
VOA 6. (*conformal weight*) $L_0 u = nu$ whenever $u \in V_n$;

VOA 7. (*locality*) $(z - w)^M [Y(u, z), Y(v, w)] = 0$ for some integer $M = M(u, v)$.

We saw the Virasoro algebra in Part 1 (see (1.2.7)). The number c in **VOA 4** is called the *central charge*, and is an important invariant of V. The peculiar-looking **VOA 7** simply says that the commutator $[Y(u, z), Y(v, w)]$ of two vertex operators will be a finite linear combination of derivatives of various orders of the Dirac delta centred at $z - w$. A recommended exercise for the reader is to show that $M = 4$ works in **VOA 7** for $u = v = \omega$. Note that in a VOA, any $Y(u, z)v$ will be a finite sum — i.e. the series $Y(u, z)$ is summable (defined last section). It is a consequence of the axioms that $1 \in V_0$ and $\omega \in V_2$: for instance, **VOA 7** says all $u_n 1 = 0$ for any $n \geq 0$, so $L_0 1 = \omega_1 1 = 0$ and hence $1 \in V_0$.

In RCFT, V would be the 'Hilbert space of states' (more carefully, V will be a dense subspace of it), and $z = e^{t+ix}$ would be a local complex coordinate on a Riemann surface. L_0 generates time translations, and so its eigenvalues (the *conformal weights*) can be identified with energy. Physically, the requirement that $V_n \to 0$ for $n \to -\infty$ corresponds to the energy of the RCFT being bounded from below. Also, $z = 0$ in **VOA 3** corresponds to the time limit $t \to -\infty$. For each state u, the vertex operator $Y(u, z)$ is a holomorphic (chiral) quantum field. The vector 1 is the vacuum $|0\rangle$, and $Y(\omega, z)$ is the stress-energy tensor T. The most important axiom, **VOA 7**, says that vertex operators commute up to a possible pole at $z = w$, and so are local quantum fields. It is equivalent to the duality axiom of many treatments of CFT. In the physics literature, there is a minor notational difference: for $u \in V_k$, $Y(u, z) = \sum u_n z^{-n-1}$ is written $\sum u_{(n)} z^{-n-k}$. (Physicists prefer this because it cleans up some formulas a little; mathematicians abhor it because it artificially prefers the 'homogeneous' vectors $u \in V_k$.)

In Segal's language (see §1.1), $Y(u, z)$ appears quite naturally. Consider the physical event of two strings combining to form a third. To first order (i.e. the tree-level Feynman diagram), this would correspond in Segal's language to a 'pair-of-pants', or a sphere with three punctures, two of which are positively oriented (corresponding to the incoming strings) and the other being negatively oriented. We can think of the sphere as the Riemann sphere $\mathbb{C}\cup\{\infty\}$; put the punctures at ∞ (outgoing) and z and 0 (the incomings). Segal's functor $\mathcal{T}$ will associate to this a z-dependent homomorphism $\varphi_z : V\times V\to V$. We write $\varphi_z(u,v)\in V$ as $Y(u,z)v$. Incidentally, the symbol 'Y' was chosen because of this 'pair-of-pants' picture (time flows from the top of the 'Y' to the bottom), as was the name 'vertex operator'.

The original axioms by Borcherds were a little more complicated and general: he didn't require $\dim(V_n)<\infty$ nor the $V_n\to 0$ condition, and he only considered L_0 and L_{-1} rather than the full Virasoro algebra. The resulting generalisation is called a *vertex algebra.*

VOA 7 can be rewritten in the form (usually called the *Jacobi identity* for the VOA)

$$z_0^{-1}\delta(\frac{z_1-z_2}{z_0})\,Y(u,z_1)\,Y(v,z_2)-z_0^{-1}\delta(\frac{z_2-z_1}{-z_0})\,Y(v,z_2)\,Y(u,z_1) \tag{2.6.1}$$
$$=z_2^{-1}\delta(\frac{z_1-z_0}{z_2})\,Y(Y(u,z_0)v,z_2)\ ,$$

where the formal series are expanded in the appropriate way. This is the embodiment of commutativity and associativity in the VOA, as we will see. To bring it into a more useful form, hit it with $t\in V$ and expand out into $z_0^\ell z_1^m z_2^n$: we obtain

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\,(u_{\ell+m-i}\circ v_{n+i}-(-1)^\ell v_{\ell+n-i}\circ u_{m+i})=\sum_{i\geq 0}\binom{m}{i}\,(u_{\ell+i}v)_{m+n-i}\ , \tag{2.6.2}$$

where for any $k\in\mathbb{Z}$, $j\in\mathbb{Z}_{\geq}$, $\binom{k}{j}:=\frac{k\,(k-1)\cdots(k-j+1)}{j!}$. For instance, specialising (2.6.2) to $\ell=0$ and $m=0$, resp., gives us

$$[u_m,v_n]=\sum_{i\geq 0}\binom{m}{i}\,(u_iv)_{m+n-i} \tag{2.6.3}$$

$$(u_\ell v)_n=\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\,(u_{\ell-i}\circ v_{n+i}-(-1)^\ell v_{\ell+n-i}\circ u_i)\ . \tag{2.6.4}$$

Why is (2.6.1) called the Jacobi identity? Put $\ell=m=n=0$ in (2.6.2): we get $u_0(v_0t)-v_0(u_0t)=(u_0v)_0t$. If we now formally write $[xy]:=x_0y$, then this becomes $[u[vt]]-[v[ut]]=[[uv]t]$, which is one of the forms of the Lie algebra Jacobi identity (1.2.1b). Even though $[xy]\neq-[yx]$ here, this formal little trick will turn out to be quite important next section.

The simplest examples of VOAs correspond to any even positive-definite lattice Λ; for their construction see e.g. [27,39]. Physically, they correspond to a bosonic string compactified on the torus $\mathbb{R}^n/\Lambda\cong S^1\times\cdots\times S^1$ (where n is the dimension of Λ); the central charge $c=n$. Other important examples, first constructed by Frenkel-Zhu (again see e.g. [27,39]), correspond to affine Kac-Moody algebras $X_\ell^{(1)}$ at level $k\in\mathbb{Z}_>$, and physically to WZW theories on simply-connected compact group manifolds. (We discussed affine algebras in §1.4.) These have central charge $c=\frac{k\dim(X_\ell)}{k+h^\vee}$.

In 1984 Frenkel-Lepowsky-Meurman [23] constructed the *Moonshine module* $V^\natural$. It is a VOA with $c = 24$, with $V^\natural = V_0^\natural \oplus V_1^\natural \oplus V_2^\natural \oplus \cdots$, where $V_0^\natural = \mathbb{C}1$ is 1-dimensional, $V_1^\natural = \{0\}$ is trivial, and $V_2^\natural = (\mathbb{C}\omega) \oplus (\text{Griess algebra})$ is $(1 + 196883)$-dimensional. Its automorphism group (=symmetry group) is precisely the Monster $\mathbb{M}$. Each graded piece $V_n^\natural$ is a finite-dimensional representation of $\mathbb{M}$; Borcherds proved that in fact $V^\natural$ is the McKay-Thompson infinite-dimensional representation of $\mathbb{M}$. It can be regarded as the most natural representation of $\mathbb{M}$ — it is rather surprising that important aspects of a finite group need to be studied via an infinite-dimensional representation.

$V^\natural$ has an elegant physical interpretation. First construct the bosonic string on $\mathbb{R}^{24}/\Lambda_{24}$ (recall that Λ_{24} is the Leech lattice). The resulting $c = 24$ VOA has partition function (=graded dimension) $J(\tau) + 24$, but although its graded pieces (at least for $n > 0$) have the right dimensions, they don't carry a natural representation of $\mathbb{M}$ and so can't qualify for the McKay-Thompson representation. To get $V^\natural$, orbifold this Λ_{24} VOA by the order-2 automorphism of Λ_{24} sending $\vec{x} \mapsto -\vec{x}$. $V^\natural$ thus corresponds to a holomorphic $c = 24$ RCFT, and Moonshine is related to physics. Most of Moonshine can be interpreted physically, except perhaps the genus 0 property of the McKay-Thompson series T_g.

There is a formal parallel between e.g. lattices and VOAs. For example, the Leech lattice Λ_{24} and the Moonshine module $V^\natural$ play analogous roles: Λ_{24} is the unique even lattice which (i) is self-dual, (ii) contains no norm 2 vectors, and (iii) has dimension 24; $V^\natural$ is believed to be the unique VOA which (i) possesses only one irreducible representation (namely itself), (ii) contains no conformal weight 1 elements, and (iii) has central charge $c = 24$. Analogies of these kinds are always useful as they suggest new directions to explore, and the history of math blooms with them. The battlecry 'Why invent what can be profitably copied' is not only heard in Hollywood.

We will end this section on a more speculative note. Witten (1986) said that to understand string theory conceptually, we need a new analogue of Riemannian geometry. Huang (1997) has pushed this thought a little further, saying that there is a more classical 'particle-math' and a more modern 'string-math'. According to Huang we have the real numbers (particle physics) vrs the complex numbers (string theory); Lie algebras vrs VOAs; and the representation theory of Lie algebras vrs RCFT, etc. What are the stringy analogues of calculus, ordinary differential equations, Riemannian manifolds, the Atiyah-Singer Index theorem,...? At present these are all unknown. However, Huang suggests that just as we could imagine Moonshine as a mystery which is explained in some way by RCFT, perhaps the stringy version of calculus would similarly explain the mystery of 2-dimensional gravity, stringy ODEs would explain the mystery of infinite-dimensional integrable systems, stringy Riemannian manifolds would help explain the mystery of mirror symmetry, and the stringy index theorem would help explain the elliptic genus.

2.7. INGREDIENT #4: GENERALISED KAC-MOODY ALGEBRAS

In this section we investigate Lie algebras arising from VOAs. These Lie algebras are an interesting generalisation of Kac-Moody algebras. See e.g. [5,6,38 Chapter 11.13, 29].

Much of Lie theory (indeed much of algebra) is developed by analogy with simple properties of integers. In §2.2 I invited you to think of a finite group as a massive generalisation of the concept of whole number. Specifically, the number n can be identified with the cyclic group $\mathbb{Z}_n$ with n elements. A divisor d of n generalises to a normal subgroup of a group. A prime number then corresponds to a simple group. Multiplying numbers corresponds to taking the semidirect product of groups (more generally, taking extensions of groups). Then we find that every group has a unique set of simple building blocks (although unlike numbers, different groups can have the same list of building blocks).

For a finite-dimensional Lie algebra, a divisor is called an ideal; a prime is called simple; and multiplying corresponds to semidirect sum. Lie algebras behave simpler than groups but not as simple as numbers, and the analogy sketched above is a reasonably satisfactory one. In particular, simple Lie algebras are important for similar reasons that simple groups are, and as mentioned in §1.2 can also be classified (with *much* less effort). A good treatment of this important classification (over $\mathbb{C}$) is provided by [36]. The proof is now reaching the state of perfection of the formulation of classical mechanics. One unobvious discovery is that the best way to capture the structure of a simple Lie algebra is by an integer matrix, called the *Cartan matrix*, or equivalently but more effectively (since most entries in the Cartan matrix are 0's) by using a graph called the *(Coxeter-)Dynkin diagram.* For instance the Dynkin diagram for A_ℓ consists of ℓ nodes connected sequentially in a line. See Figure 6 in [59].

More precisely, define a *symmetrised Cartan matrix* to be a symmetric real matrix $A = (a_{ij})_{i,j\leq\ell}$ such that $a_{ij} \leq 0$ if $i \neq j$, $a_{ii} > 0$, each $2\frac{a_{ij}}{a_{ii}} \in \mathbb{Z}$, and A is positive-definite. Examples of 2×2 symmetrised Cartan matrices are[32]

$$\begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \quad \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, \quad \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}, \quad \begin{pmatrix} 2 & -3 \\ -3 & 6 \end{pmatrix}$$

The Dynkin diagram corresponding to A consists of ℓ nodes; the ith and jth nodes are connected with $4a_{ij}^2/a_{ii}a_{jj}$ lines, and if $a_{ii} \neq a_{jj}$, then we put an arrow over those lines pointing to i if $a_{ii} < a_{jj}$. The Dynkin diagrams corresponding to those four Cartan matrices are respectively

 ,  ,  , 
We may without loss of generality require A to be *indecomposable*, or equivalently that the Dynkin diagram be connected. Of the 4 given above, only the second is decomposable.

To any $\ell \times \ell$ symmetrisable Cartan matrix, we can construct the corresponding Lie algebra $\mathfrak{g}$ in the following way. For each i, create 3 generators e_i, f_i, h_i (so there are a total of 3ℓ generators). The relations these generators obey are given by the following brackets: $[e_i f_j] = \delta_{ij} h_i$, $[h_i e_j] = a_{ij} e_j$, $[h_i f_j] = -a_{ij} f_j$, and for $i \neq j$ $\mathrm{ad}(e_i)^n e_j = \mathrm{ad}(f_i)^n f_j = 0$ where $n = 1 - 2\frac{a_{ij}}{a_{ii}}$. By 'ad$(e)$' here I mean the function $\mathfrak{g} \to \mathfrak{g}$ defined by $\mathrm{ad}(e)f = [ef]$. So $\mathrm{ad}(e)^2 f = [e[ef]]$, $\mathrm{ad}(e)^3 f = [e[e[ef]]]$, etc.

---

[32] Note that our Cartan matrices differ from the usual definition, in which every diagonal entry equals 2.

To get a better feeling for these relations, consider a fixed i. The generators $e = \sqrt{\frac{2}{a_{ii}}}\, e_i, f = \sqrt{\frac{2}{a_{ii}}}\, f_i, h = \frac{2}{a_{ii}}\, h_i$ obey the relations (1.2.2b). In other words, every node in the Dynkin diagram corresponds to a copy of the A_1 Lie algebra. The lines connecting these nodes tells how these ℓ copies of A_1 intertwine.

For instance consider the first Cartan matrix given above. It corresponds to the Lie algebra A_2, or $\mathrm{sl}_3(\mathbb{C})$. The two A_1 subalgebras which generate it (corresponding to the 2 nodes of the Dynkin diagram) can be chosen to be the trace-zero matrices of the form

$$\begin{pmatrix} \star & \star & 0 \\ \star & \star & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad \begin{pmatrix} 0 & 0 & 0 \\ 0 & \star & \star \\ 0 & \star & \star \end{pmatrix}.$$

It can be shown that the Lie algebra corresponding to an indecomposable symmetrised Cartan matrix will be finite-dimensional and simple, and conversely that any finite-dimensional simple Lie algebra corresponds to an indecomposable symmetrisable Cartan matrix in this way.

A confusion sometimes arises between the terms 'generators' and 'basis'. Both generators and basis vectors build up the whole algebra; the difference lies in which operations you are permitted to use. For a basis, you are only allowed to use linear combinations (i.e. addition of vectors and multiplication by numbers), while for generators you are also permitted multiplication of vectors (or the bracket, in the Lie case). 'Dimension' refers to basis, while 'rank' usually refers in some way to generators. For instance the (commutative associative) algebra of polynomials in one variable x is infinite-dimensional — any basis needs infinitely many vectors. However, the single polynomial x is enough to generate it (so we could say that its rank is 1). Although those Lie algebras have 3ℓ generators, their dimensions in general will be greater.

From the point of view of generators and relations, the step from 'finite-dimensional simple' to 'symmetrisable Kac-Moody' is rather easy: the only difference is that we drop the 'positive-definite' condition (which was responsible for finite-dimensionality). Kac-Moody (KM) algebras are also generated by (finitely many) A_1 subalgebras, and their theory is quite parallel to that of the simple algebras. Compare Figures 6 and 9 in [59].

Now, it is easy to generalise something; the challenge is to generalise it in a rich and interesting direction. One natural and appealing strategy for generalisation was followed instinctively by a grad student named Robert Moody. Moody's original motivation for developing the theory of Kac-Moody algebras was the Weyl group. If there were Lie algebras for finite Coxeter groups, he asked, why not also for the Euclidean (=affine) ones? For another example of this style of generalisation, consider the question: What is the analogue of calculus (or manifolds) over weird fields — fields (like $\mathbb{Z}_p$) for which the usual limit definitions make no sense? This question leads to the riches of algebraic geometry. Nevertheless this generalisation strategy, even in the hands of a master, will not always be successful. For instance, consider all the trouble the following metaphor has caused: my watch has a maker, so so should the Universe.

Recently Borcherds produced a further generalisation of finite-dimensional simple Lie algebras, which is rather less obvious than that of Kac-Moody algebras. It is easy to associate a Lie algebra to a matrix A, but which class of matrices will yield a deep theory?

Borcherds found such a class by holding in his hand a single algebra (the fake Monster Lie algebra, see §2.9) which acted a lot like a KM algebra, even though it had 'imaginary simple roots'.

By a *generalised symmetrised Cartan matrix* $A = (a_{ij})$ we will mean a symmetric real matrix (possibly infinite), such that $a_{ij} \leq 0$ if $i \neq j$, and if $a_{ii} > 0$ then $2\frac{a_{ij}}{a_{ii}} \in \mathbb{Z}$ for all j. By a *universal generalised Kac-Moody algebra* (universal GKM) or *universal Borcherds-Kac-Moody algebra* $\mathfrak{g}$ we mean the algebra[33] with generators e_i, f_i, h_{ij}, and with relations: $[e_i f_j] = h_{ij}$; $[h_{ij} e_k] = \delta_{ij} a_{ik} e_k$; $[h_{ij} f_k] = -\delta_{ij} a_{ik} f_k$; if $a_{ii} > 0$ and $i \neq j$ then $\mathrm{ad}(e_i)^n e_j = \mathrm{ad}(f_i)^n f_j = 0$ for $n = 1 - 2\frac{a_{ij}}{a_{ii}}$; and if $a_{ij} = 0$ then $[e_i e_j] = [f_i f_j] = 0$.

For example the Heisenberg algebra (1.2.3) corresponds to the choice $A = (0)$, while any other 1×1 $A = (a)$ corresponds to A_1. A universal GKM algebra differs from a KM algebra in that it is built up from Heisenberg algebras as well as A_1, and these subalgebras intertwine in more complicated ways. Nevertheless *much of the theory for finite-dimensional simple Lie algebras continues to find an analogue in this much more general setting* (e.g. root-space decomposition, Weyl group, character formula,...). This unexpected fact is the point of GKM algebras.

To get a feel for these algebras, let us prove a few simple results concerning the h_{ij}. Note first that, using the above relations together with the Jacobi identity, we obtain $[h_{ij} h_{k\ell}] = \delta_{ij}(a_{jk} - a_{j\ell}) h_{k\ell}$. Comparing this with $[h_{k\ell} h_{ij}] = -[h_{ij} h_{k\ell}]$, we see that bracket must always equal 0. Hence all h's pairwise commute, and $h_{ij} = 0$ unless the ith and jth columns of A are identical. An easy exercise now is to show that when $i \neq j$, h_{ij} will lie in the centre of the algebra (i.e. h_{ij} will commute with all other generators).

Although the definition of universal GKM algebra is more natural, it turns out that an equivalent form can be more useful in practice. (It's simpler to describe over $\mathbb{R}$, so in most expositions the reals are used, but alas it's far too late for us to switch loyalties now.) By a *generalised Kac-Moody algebra* (or *Borcherds-Kac-Moody algebra*) $\mathfrak{g}$, we mean a (complex!) Lie algebra which is:

- $\mathbb{Z}$-graded, i.e. $\mathfrak{g} = \oplus_i \mathfrak{g}_i$, where $[\mathfrak{g}_i \mathfrak{g}_j] \subseteq \mathfrak{g}_{i+j}$;
- $\mathfrak{g}_i$ is finite-dimensional for $i \neq 0$;
- $\mathfrak{g}$ has an antilinear involution ω (i.e. $\omega(kx + y) = k^* \omega(x) + \omega(y)$, $[\omega(x)\omega(y)] = \omega([xy])$, and $\omega \circ \omega = id$.) which maps $\mathfrak{g}_i$ to $\mathfrak{g}_{-i}$ and acts as multiplication by -1 on some basis of $\mathfrak{g}_0$;
- $\mathfrak{g}$ has an invariant symmetric bilinear form $(\star, \star)$ (i.e. $([xy], z) = (x, [yz])$ and $(y, z) = (z, y) \in \mathbb{C}$), obeying $(\omega(x), \omega(y)) = (x, y)^*$, such that $(\mathfrak{g}_i, \mathfrak{g}_j) = 0$ if $i \neq -j$;
- the Hermitian form defined by $(x|y) := -(\omega(x), y)$ is positive-definite on $\mathfrak{g}_{i \neq 0}$.

Note that for some basis x_i of $\mathfrak{g}_0$, the third condition tells us $-[x_i x_j] = [(-x_i)(-x_j)] = [x_i x_j]$, i.e. $\mathfrak{g}_0$ has a trivial bracket. It plays the role of the Cartan subalgebra $\mathfrak{h}$ in the theory.

For example, let $\mathfrak{g} = \mathrm{sl}_2(\mathbb{C})$ and recall (1.2.5). Then $\mathfrak{g}_1 = \mathbb{C}e$, $\mathfrak{g}_0 = \mathbb{C}h$, $\mathfrak{g}_{-1} = \mathbb{C}f$ is the root-space decomposition. $\omega(x) = -x^\dagger$ is the Cartan involution. $(x, y) = \mathrm{tr}(xy)$ is the Killing form.

---

[33] As with KM algebras, usually we want to extend it by some derivations; enough derivations are added so that the simple roots are linearly independent.

It turns out [5] that any universal GKM algebra is a GKM algebra, and any GKM algebra can be constructed from a unique universal GKM algebra (by quotienting out part of the centre and adding derivations), so in that sense the two structures are equivalent. This theorem is important, because it tells us that *GKM algebras are the ultimate generalisation of simple Lie algebras,* in the sense that any further generalisation will lose some basic structural ingredient.

We know simple Lie algebras (and groups) arise in both classical and quantum physics, and the affine KM algebras are important in CFT, as we saw in Part 1. GKM algebras have recently appeared in the physics literature (see Harvey-Moore) in the context of BPS states in string theory.

How do GKM algebras arise in VOAs? If we define $[xy] := x_0 y$, then as mentioned in §2.6 we get from the VOA Jacobi identity the equation $[x[yz]] - [y[xz]] = [[xy]z]$. Thus our bracket will be anti-associative if it is anti-commutative. But is it anti-commutative? It can be shown

$$u_n v = \sum_{i=0}^{\infty} \frac{1}{i!}(-1)^{i+n+1}(L_{-1})^i (v_{n+i} u) \tag{2.7.1}$$

so $u_0 v \equiv -v_0 u$ if we look at things mod $L_{-1}V$.

Since our bracket is clearly bilinear, we thus get a Lie algebra structure on $V/L_{-1}V$. Similarly, we get a symmetric bilinear product on $V/L_{-1}V$, given by $\langle u, v\rangle := u_1 v$.

We would like $\langle \star, \star\rangle$ to respect the Lie algebra structure, i.e. be $[\star\star]$-invariant. We compute from (2.6.4)

$$\langle [uv], t\rangle = -[v\langle u, t\rangle] + \langle u, [vt]\rangle \ . \tag{2.7.2}$$

Since we would like to identify $\langle \star, \star\rangle$ with the bilinear form in the GKM algebra definition, we also would like it to be number-valued (i.e. have 1-dimensional range).

There is a simple way to satisfy both of these. First, restrict attention to V_1, i.e. the conformal weight 1 vectors: $V_1 \cap (V/L_{-1}V) = V_1/L_{-1}V_0$. Then $\langle u, v\rangle \in V_0$. Assume V_0 is 1-dimensional: i.e. $V_0 = \mathbb{C}1$. Then $\langle u, v\rangle$ will equal a number times 1, so call (u, v) that number. Also, $[\langle u, t\rangle v] = (u, t)1_0 v = 0$, so $\langle \star, \star\rangle$ and hence $(\star, \star)$, will be invariant. Of course, when $V_0 = \mathbb{C}1$, $L_{-1}V_0 = \{0\}$.

$V_1/L_{-1}V_0$ is generally too large in practice to be useful; a subalgebra can be defined as follows. Let P_n be the 'primary states with conformal weight n', i.e. the $u \in V_n$ killed by L_m for all $m > 0$. Then $\mathfrak{g}(V) := P_1/L_{-1}P_0$ will be a subalgebra of $V_1/L_{-1}V_0$. Through the assignment $u \mapsto u_0$, $\mathfrak{g}(V)$ acts on V and this action commutes with that of L_i. This association of a Lie algebra to a VOA is due to Borcherds (1986).

Similar arguments show that when V_0 is 1-dimensional and V_1 is 0-dimensional, then V_2 will necessarily be a commutative nonassociative algebra with product $u \times v := u_1 v \in V_2$ and identity element $\frac{1}{2}\omega$ (*proof*: $\omega \times u = L_0 u = 2u$). Now, those conditions on V_0, V_1 are satisfied by the Moonshine module $V^\natural$. We find that $V_2^\natural$ is none other than the Griess algebra extended by an identity element.

2.8. INGREDIENT #5: DENOMINATOR IDENTITIES

In §1.3, we discussed the representation theory of Lie algebras. An important invariant of a representation is its *character*. Simple Lie algebras possess a very useful formula for their characters, due to Weyl:

$$\mathrm{ch}_\lambda(z) := \sum_\mu \dim(L_\lambda(\mu))\, e^{\mu\cdot z} = e^{-\rho\cdot z}\, \frac{\sum_{w\in W} \pm e^{w(\lambda+\rho)\cdot z}}{\prod_{\alpha\in\Delta_+}(1-e^{-\alpha\cdot z})}\ , \tag{2.8.1}$$

where W is the Weyl group, Δ_+ the positive roots, and where $\oplus_\mu L_\lambda(\mu)$ is the weight-space decomposition of L_λ — i.e. the simultaneous eigenspaces of the h_i. Here z belongs to the Cartan subalgebra $\mathfrak{h}$; the character is complex-valued. Analogous statements hold for all GKM algebras.

It is rare indeed when a trivial special case of a theorem or formula produces something interesting. But that is what happens here. Consider the trivial representation: i.e. $x \mapsto 0$ for all $x \in X_\ell$. Then the character is identically 1, by definition: $ch_0 \equiv 1$. Thus the character formula tells us that a certain alternating sum over a Weyl group, equals a certain product over positive roots. These formulas, called *denominator formulas*, are nontrivial even in the finite-dimensional cases.

Consider for instance the smallest simple algebra, A_1. Here the identity indeed is too trivial: it reads $e^{z/2} - e^{-z/2} = e^{z/2}(1-e^{-z})$. For A_2 we get a sum of 6 terms equalling a product of 3 terms, and the complexity continues to rise from there.

Around 1970 Macdonald tried to generalise these finite denominator identities to infinite identities, corresponding to the extended Dynkin diagrams. These were later reinterpreted by Kac, Moody and others as denominator identities for affine nontwisted KM algebras. The simplest one was known classically as the Jacobi triple product identity:

$$\sum_{n=-\infty}^{\infty}(-1)^n x^{n^2} y^n = \prod_{m=1}^{\infty}(1-x^{2m})(1-x^{2m-1}y)(1-x^{2m-1}y^{-1})$$

We now know it to be the denominator identity for the simplest infinite-dimensional KM algebra, $A_1^{(1)}$.

Freeman Dyson is famous for his work in quantum field theory, but he started as an undergraduate in number theory and still enjoys it as a hobby. Dyson [20] found a curious formula for the Ramanujan τ-function, which can be defined by the generating function $\sum_{n=1}^\infty \tau(n)x^n = \eta^{24}(x) := x\prod_{m=1}^\infty (1-x^m)^{24}$. Dyson found the remarkable formula

$$\tau(n) = \sum \frac{(a-b)(a-c)(a-d)(a-e)(b-c)(b-d)(b-e)(c-d)(c-e)(d-e)}{1!\ 2!\ 3!\ 4!}$$

where the sum is over all 5-tuples $(a,b,c,d,e) \equiv (1,2,3,4,5) \pmod 5$ obeying $a+b+c+d+e=0$ and $a^2+b^2+c^2+d^2+e^2 = 10n$. Using this, an analogous formula can be found for η^{24}. Dyson knew that similar-looking formulas were also known for η^d for the values $d = 3, 8, 10, 14, 15, 21, 24, 26, 28, 35, 36, \ldots$.

What was ironic was that Dyson found that formula at the same time that Macdonald was finding the Macdonald identities. Both were at Princeton then, and would often chat a little when they bumped into each other after dropping off their daughters at school. But they never discussed work. Dyson didn't realise that his strange list of numbers has a simple interpretation: they are precisely the dimensions of the simple Lie algebras! $3 = \dim(\mathrm{A}_1)$, $8 = \dim(A_2)$, $10 = \dim(C_2)$, $14 = \dim(G_2)$, etc. In fact these formulas for η^d are none other than (specialisations of) the Macdonald identities. For example, Dyson's formula is the denominator formula for $A_4^{(1)}$ ($24 = \dim(A_4)$). If they had spoken, they would probably have anticipated the affine denominator identity interpretation.

One curiousity apparently still has no algebraic interpretation: No simple Lie algebra has dimension 26, so the formula for η^{26} can't correspond to any Macdonald identity.

Macdonald didn't close the book on denominator identities. More recently Kac and Wakimoto [40] have used denominator identities for Lie superalgebras to obtain nice formulas for various generator functions involving sums of squares, sums of triangular numbers (triangular numbers are numbers of the form $\frac{1}{2}k(k+1)$), etc. For instance, the number of ways n can be written as a sum of 16 triangular numbers is

$$\frac{1}{3\cdot 4^3}\sum ab\,(a^2-b^2)^2$$

where the sum is over all odd positive integers a, b, r, s obeying $ar + bs = 2n + 4$ and $a > b$.

Another example of denominator identities is Borcherds' use of them in proving the Moonshine conjectures. In particular this motivated his introduction of the GKM algebras. The denominator identities for other GKM algebras were used by Borcherds to obtain results on the moduli spaces of e.g. families of K3 surfaces. They are also often turned-around now and used for learning about the positive roots in a given GKM.

2.9. PROOF OF THE MOONSHINE CONJECTURES

The main Conway-Norton conjecture was proved almost immediately. Thompson showed that if $g \mapsto a_n(g)$ is a character for all $n \leq 1200$, then it will be for all n. He also showed that if certain congruence conditions hold for a certain number of $a_n(g)$ (all with $n \leq 100$), then all $g \mapsto a_n(g)$ will be *virtual* characters (i.e. a linear combination over $\mathbb{Z}$ of irreducible characters of $\mathbb{M}$; only if all coefficients are nonnegative will it be a true character). Atkin-Fong-Smith [54] used that to prove on a computer that indeed all were virtual characters. But their work didn't say anything about the underlying (possibly virtual) representation V. The real challenge was to construct (preferably in a natural manner) the representation which works. Frenkel-Lepowsky-Meurman [23] constructed a candidate for it (the Moonshine module $V^\natural$); it was Borcherds who finally proved $V^\natural$ obeyed the Conway-Norton conjecture. A good overview of Borcherds' work on Moonshine is provided in [32].

We want to show that the McKay-Thompson series $T_g(\tau) := q^{-1}\mathrm{tr}_{V^\natural}(gq^{L_0})$ of (2.1.4) equals the Hauptmodul $J_g(\tau)$ in (2.4.1) (the 'fudge factor' $q^{-1} = q^{-c/24}$ is familiar to e.g. KM algebras and CFT and was discussed at the end of §1.2). Borcherds' strategy was to bring in Lie theory and to use the corresponding denominator identity to provide useful combinatorial data. The first guess for this 'Monster Lie algebra' was the Kac-Moody algebra whose Dynkin diagram is essentially the Leech lattice (i.e. a node for each vector in Λ_{24}, and 2 nodes are connected by a number of edges depending on the value of a certain dot product). It was eventually discarded because some of the critical data (namely positive root multiplicities) needed in order to write down its denominator identity were too complicated. But looking at that failed attempt led Borcherds to a second candidate, now called the *fake Monster Lie algebra* $\mathfrak{g}'_{\mathbb{M}}$. In order to *construct* it, he developed the theory of VOAs; and in order to *understand* it, he developed the theory of GKM algebras. We will define it shortly. $\mathfrak{g}'_{\mathbb{M}}$ also turned out to be inadequate for proving the Moonshine conjectures; however it directly led him to the GKM algebra now called the true *Monster Lie algebra* $\mathfrak{g}_{\mathbb{M}}$. And that directly led to the proof of Moonshine.

Step 1: Construct $\mathfrak{g}_{\mathbb{M}}$ from $V^\natural = V_0^\natural \oplus V_1^\natural \oplus \cdots$. For later convenience, reparametrise these subspaces $V^i := V_{i+1}^\natural$. Recall the even indefinite lattice $II_{1,1}$ defined in (1.6.1). Of course the direct choice $\mathfrak{g}(V^\natural)$ is 0-dimensional because $V_1^\natural$ is trivial, so we must modify $V^\natural$ first.

The Monster Lie algebra is (essentially) defined to be the Lie algebra $\mathfrak{g}(V^\natural \otimes V_{II_{1,1}})$ associated to the vertex algebra $V^\natural \otimes V_{II_{1,1}}$ (strictly speaking, more of $\mathfrak{g}$ is quotiented away). By contrast, the fake Monster is the Lie algebra associated to the vertex algebra $V_{\Lambda_{24}} \otimes V_{II_{1,1}} \cong V_{II_{25,1}}$. Both of these are vertex algebras as opposed to VOAs, because of the presence of the indefinite lattices, but this isn't important here. $\mathfrak{g}_{\mathbb{M}}$ inherits a $II_{1,1}$-grading from $V_{II_{1,1}}$: the piece of grading (m,n) is isomorphic (as a vector space) to V^{mn}, if $(m,n) \neq (0,0)$; the (0,0) piece is isomorphic to $\mathbb{R}^2$. Borcherds uses the No-Ghost Theorem of string theory to show that the homogeneous pieces of $\mathfrak{g}_{\mathbb{M}}$ are those of $V^\natural$.

Both $\mathfrak{g}_{\mathbb{M}}$ and $\mathfrak{g}'_{\mathbb{M}}$ are GKM algebras; for instance the $\mathbb{Z}$-grading of $\mathfrak{g}_{\mathbb{M}}$ is given by $(\mathfrak{g}_{\mathbb{M}})_k = \oplus_{m+n=k} V^{mn}$ for $k \neq 0$, while the 0-part is $V^{-1} \oplus V^{-1}$. Although $\mathfrak{g}'_{\mathbb{M}}$ is not used in the proof of the Monstrous Moonshine conjectures, it is related to some kind of Moonshine for the finite simple group .1, which is 'half' of the automorphism group .0 of the Leech lattice Λ_{24}. $\mathfrak{g}_{\mathbb{M}}$ corresponds to the Cartan matrix

$$\begin{pmatrix} B_{-1,-1} & B_{-1,1} & B_{-1,2} & \cdots \\ B_{1,-1} & B_{1,1} & B_{1,2} & \cdots \\ B_{2,-1} & B_{2,1} & B_{2,2} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix},$$

where $B_{i,j}$ for $i,j \in \{-1,1,2,3,\ldots\}$ is the $a_i \times a_j$ block with fixed entry $-i-j$ (the a_i as usual are the coefficients $\sum_n a_n q^n$ of $j - 744$).

2nd step: Compute the denominator identity of $\mathfrak{g}_{\mathbb{M}}$: we get

$$p^{-1} \prod_{\substack{m>0 \\ n\in\mathbb{Z}}} (1 - p^m q^n)^{a_{mn}} = j(z) - j(\tau) \tag{2.9.1}$$

where $p = e^{2\pi \mathrm{i} z}$. The result are various formulas involving the coefficients a_i, for instance $a_4 = a_3 + (a_1^2 - a_1)/2$. It turns out to be possible to 'twist' (2.9.1) by each $g \in \mathbb{M}$, obtaining

$$p^{-1} \exp[-\sum_{k>0} \sum_{\substack{m>0 \\ n\in\mathbb{Z}}} a_{mn}(g^k) \frac{p^{mk} q^{nk}}{k}] = T_g(z) - T_g(\tau)\ . \tag{2.9.2}$$

This looks a lot more complicated, but you can glimpse the Taylor expansion of $\ln(1-p^m q^n)$ there and in fact for $g = id$ (2.9.2) reduces to (2.9.1). This formula gives more generally identities like $a_4(g) = a_2(g) + (a_1(g)^2 - a_1(g^2))/2$, where $T_g(\tau) = \sum_i a_i(g) q^i$. These formulas involving the McKay-Thompson coefficients are equivalent to the replication formulae conjectured in §2.4.

3rd step: It was known earlier that all of the Hauptmoduls also obey those replication formula, and that anything obeying them will lie in a finite-dimensional manifold which we'll call R. In particular, if $B(q) = q^{-1} + \sum_{n>0} b_n q^n$ and $C(q) = q^{-1} + \sum_{n>0} c_n q^n$ both lie in R, and $b_n = c_n$ for $n \leq 23$, then $B(q) = C(q)$. In fact, it turns out that if we verify for each conjugacy class $[g]$ of $\mathbb{M}$ that the first, second, third, fourth and sixth coefficients of the McKay-Thompson series T_g and the corresponding Hauptmodul J_g agree, then $T_g = J_g$, and we are done.

That is precisely what Borcherds then did: he compared finitely many coefficients, and as they all equalled what they should, this concluded the proof of Monstrous Moonshine!

However there was a disappointing side to his proof. While no one disputed its *logical* validity, it did seem to possess a disappointing *conceptual gap*. In particular, the Moonshine conjectures were made in the hope that proving them would help explain what the Monster had to do with the j-function and the other Hauptmoduls. A good proof says much more than 'True' or 'False'. The case-by-case verification occurred at the critical point where the McKay-Thompson series were being compared directly to the Hauptmoduls. The proof showed that indeed the Moonshine module establishes some sort of relation between T_g and J_g (namely, they must lie in the same finite-dimensional space), but why couldn't it be just a happy meaningless accident that they be equal? Of course we believe it's more than merely an accident, so our proof should reflect this: we want a more conceptual explanation.

This conceptual gap has since been filled [17] — i.e. the case-by-case verification has been replaced with a general theorem. It turns out that something obeying the replicable formulas will also obey something called *modular equations*. A modular equation for a function f is a polynomial identity obeyed by $f(x)$ and $f(nx)$. The simplest examples come from the exponential and cosine functions: note that for any $n > 0$, $\exp(nx) = (\exp(x))^n$ and $\cos(nx) = T_n(\cos(x))$ where T_n is a Tchebychev polynomial. A more interesting example of a modular equation is obeyed by $J(\tau) = j(\tau) - 744$: put $X = J(\tau)$ and $Y = J(2\tau)$, then

$$(X^2 - Y)(Y^2 - X) = 393768\,(X^2 + Y^2) + 42987520\,XY + 40491318744\,(X + Y) \\ - 120981708338256\ .$$

Finding modular equations (for various elliptic functions) was a passion of the great mathematician Ramanujan. His notebooks are filled with them. See e.g. [7] for an application of Ramanujan's modular equations to computing the first billion or so digits of π. Many modular equations are also studied in [10]. For more of their applications, see e.g. [16]. It can be shown that the only functions $f(\tau) = q^{-1} + a_1 q + \cdots$ which obey modular equations for all n, are $J(\tau)$ and the 'modular fictions' q^{-1} and $q^{-1} \pm q$ (which are essentially exp, cos, and sin).

It was proved in [17] that, roughly speaking, a function $B(\tau) = q^{-1} + \sum_{n>0} b_n q^n$ which obeys enough modular equations, will either be of the form $B(\tau) = q^{-1} + b_1 q$, or will necessarily be a Hauptmodul for a modular group containing some $\Gamma_0(N)$. The converse is also true: for instance, a modular equation for the Hauptmodul J_{25} of $\Gamma_0(25)$ given in (2.3.5) is

$$(X^2 - Y)(Y^2 - X) = -2\,(X^2 + Y^2) + 4\,(X + Y) - 4\ ,$$

where $X = J_{25}(\tau)$ and $Y = J_{25}(2\tau)$. To eliminate the conceptual gap, this result should then replace step 3. Steps 1 and 2 are still required, however.

This conceptual gap should not take away from what was a remarkable accomplishment by Borcherds: not only the proof of the Monstrous Moonshine conjectures, but also the definition of two new and important algebraic structures. I hope the preceding sections give the reader some indication of why Borcherds was awarded one of the 1998 Fields Medals.

Another approach to the Hauptmodul property is by Tuite [57], who related it to the (conjectured) uniqueness of $V^\natural$. Norton has suggested that the reason $\mathbb{M}$ is associated to *genus-zero* modular functions could be what he calls its '6-transposition' property [47].

So has Moonshine been explained? According to Conway, McKay, and many others, it hasn't. They consider VOAs in general, and $V^\natural$ in particular, to be too complicated to be God-given. The progress, though impressive, has broadened not lessened the fundamental mystery, they would argue.

For what it's worth, I don't completely agree. Explaining away a mystery is a little like grasping a bar of soap in a bathtub, or quenching a child's curiousity. Only extreme measures like pulling the plug, or enrollment in school, ever really work. True progress means displacing the mystery, usually from the particular to the general. Why is the sky blue? Because of how light scatters in gases. Why are Hauptmoduls attached to each $g \in \mathbb{M}$? Because of $V^\natural$. Mystery exists wherever we can ask 'why' — like beauty it's in the beholder's eye.

Moonshine is now 'leaving the nest'. We are entering a consolation phase, tidying up, generalising, simplifying, clarifying, working out more examples. Important and interesting discoveries will be made in the next few years, and yes there still is mystery, but no longer does a Moonshiner feel like an illicit distiller: Moonshine is now a day-job!

Acknowledgments. I warmly thank the Feza Gursey Institute in Istanbul, and in particular Teoman Turgut, for their invitation to the workshop and hospitality during my month-long stay. These notes are based on 16 lectures I gave there in Summer 1998. I've also benefitted from numerous conversations with Y. Billig, A. Coste, C. Cummins, M. Gaberdiel, J. McKay, M. Tuite, and M. Walton — Mark Walton in particular made a very careful reading of the manuscript (and hence must share partial blame for any errors still remaining). My appreciation as well goes to J.-B. Zuber and P. Ruelle for sharing with me their personal stories behind the discoveries of, respectively, A-D-E in $A_1^{(1)}$ and Fermat in $A_2^{(1)}$. The research was supported in part by NSERC.

Monstrous Moonshine: The first twenty-five years

Terry Gannon

Abstract

Twenty-five years ago, Conway and Norton published in this journal[†] their remarkable paper 'Monstrous Moonshine', proposing a completely unexpected relationship between finite simple groups and modular functions. This paper reviews the progress made in broadening and understanding that relationship.

1. Introduction

It has been approximately twenty-five years since John McKay remarked that

$$196\,884 = 196\,883 + 1\ . \tag{1.1}$$

That time has seen the discovery of important structures, the establishment of another deep connection between number theory and algebra, and a reinforcement of a new era of cooperation between pure mathematics and mathematical physics. It is a beautiful and accessible example of how mathematics can be driven by strictly conceptual concerns, and of how the particular and the general can feed off each other. Now, six years after Borcherds' Fields Medal, the original flurry of activity is over; the new period should be one of consolidation and generalisation and should witness the gradual movement of this still rather esoteric corner of mathematics toward the mainstream.

The central question McKay's equation (1.1) raises, is: What does the j-function (the left side) have to do with the Monster finite group (the right side)? Many would argue that we still don't have our finger on the essence of the matter. But what is clear is that we understand far more about this central question today than we did in 1978. Today we say that there is a vertex operator algebra, called the *Moonshine module* $V^\natural$, which interpolates between the left and right sides of (1.1): its automorphism group is the Monster and its graded dimension is the j-function (-744).

This paper tries to summarise this work of the past twenty-five years in about as many pages. The original article [**24**] is still very readable and contains a wealth of information not found in other sources. Other reviews are [**21**], [**87**], [**12**], [**39**], [**90**], [**48**], [**15**], [**78**], [**102**], [**16**], [**46**] and the introductory chapter in [**44**], and each has its own emphasis. Our own bias here has been to breadth at the expense of depth, which probably limits this review to be a mere annotated sampling of representative literature.

2. Background

In §2.1 we describe the finite simple groups and in particular the Monster. In §2.2 we focus on the modular groups and functions which arise in Monstrous Moonshine.

2.1. The Monster. By definition, a simple group is one whose only normal subgroups are the trivial ones: {1} and the group itself. The importance of the finite simple groups lies in their role as building blocks, in the sense that any finite group G can be constructed from $\{1\}$ by extending successively by a (unique up to order) sequence of finite simple groups. For example the symmetric group S_4 arises in this way from the cyclic groups C_2, C_2, C_3, C_2.

[†] This is an invited paper for the *Bull. London Math. Soc.* Comments are welcome.

2000 *Mathematics Subject Classification* 11F22, 17B69, 17B67, 81T40

A formidable accomplishment last century was determining the explicit list of all finite simple groups. See e.g. [**49**] for more details and references. These groups are:

(i) the cyclic groups C_p, p prime;
(ii) the alternating groups A_n, $n \geq 5$;
(iii) 16 infinite families of groups of Lie type;
(iv) 26 sporadic groups.

An example of a family of finite simple group of Lie type is $\mathrm{PSL}_n(\mathbb{F}_q)$, i.e. the group of $n \times n$ matrices with determinant 1, and entries from the finite field $\mathbb{F}_q$, quotiented out by its centre (the scalar matrices aI, where $a^n = 1$).

The mysteriousness of the sporadics is due to their falling outside those infinite families. They range in size from the Mathieu group M_{11}, with order 7920 and discovered in 1861, to the Monster $\mathbb{M}$, with order

$$|\mathbb{M}| = 2^{45} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71 \approx 8 \times 10^{53} \ . \tag{2.1}$$

The existence of $\mathbb{M}$ was conjectured in 1973 by Fischer and Griess, and finally constructed in 1980 by Griess [**50**]. Most sporadics arise in $\mathbb{M}$ (e.g. as quotients of subgroups). We'll encounter many of these sporadics in the coming pages, but most of our attention will be directed at $\mathbb{M}$.

Griess showed in fact that $\mathbb{M}$ was the automorphism group of a 196883-dimensional commutative nonassociative algebra, now called the *Griess algebra*, but the construction was somewhat artificial. We now understand [**44**] the Griess algebra as the first nontrivial tier of an infinite-dimensional graded algebra, the *Moonshine module* $V^\natural$, which lies at the heart of Monstrous Moonshine. We'll discuss $V^\natural$ in §4.2; we will find that it has a very rich algebraic structure, is conjectured to obey a strong uniqueness property, and has automorphism group $\mathbb{M}$.

The Monster $\mathbb{M}$ has a remarkably simple presentation. As with any noncyclic finite simple group, it is generated by its involutions (i.e. elements of order 2) and so will be a homomorphic image of a Coxeter group. Let $\mathcal{G}_{pqr}$, $p \geq q \geq r \geq 2$, be the graph consisting of three strands of lengths $p+1, q+1, r+1$, sharing a common endpoint. Label the $p+q+r+1$ nodes as in Figure 1. Given any graph $\mathcal{G}_{pqr}$, define Y_{pqr} to be the group consisting of a generator for each node, obeying the usual Coxeter group relations (i.e. all generators are involutions, and the product gg' of two generators has order 3 or 2, depending on whether or not the two nodes are adjacent), together with one more relation:

$$(ab_1b_2ac_1c_2ad_1d_2)^{10} = 1 \ . \tag{2.2}$$

The groups Y_{pqr}, for $p \leq 5$, have now all been identified (see e.g. [**61**]). Conway conjectured and, building on work by Ivanov [**60**], Norton proved [**98**] that $Y_{555} \cong Y_{444}$ is the 'Bimonster', the wreathed-square $\mathbb{M} \wr C_2$ of the Monster (so has order $2|\mathbb{M}|^2$). A closely related presentation of the Bimonster has 26 involutions as generators and has relations given by the incidence graph of the projective plane of order 3; the Monster itself arises from 21 involutions and the affine plane of order 3 [**25**]. Likewise, $Y_{553} \cong Y_{443} \cong \mathbb{M} \times C_2$. Other sporadics arise in e.g. $Y_{533} \cong Y_{433}$ (the Baby Monster $\mathbb{B}$), $Y_{552} \cong Y_{442}$ (the Fischer group Fi'_{24}), and $Y_{532} \cong Y_{432}$ (the Fischer group Fi_{23}). The Coxeter groups of $\mathcal{G}_{555}$, $\mathcal{G}_{553}$, $\mathcal{G}_{533}$, $\mathcal{G}_{552}$, and $\mathcal{G}_{532}$, are all infinite groups of hyperbolic reflections in e.g. $\mathbb{R}^{17,1}$, and contain copies of groups such as the affine E_8 Weyl group, so the geometry here should be quite pretty. What role, if any, these remarkable presentations have in Moonshine hasn't been established yet. As a first step though, [**97**] identifies in $\mathrm{Aut}(V^\natural)$ the 21 involutions generating $\mathbb{M}$.

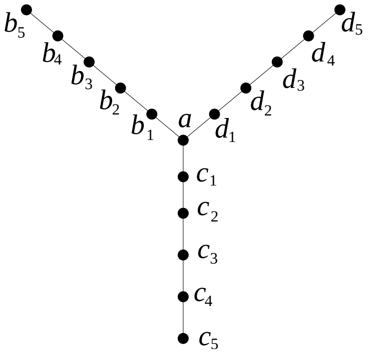

Figure 1. The graph $\mathcal{G}_{555}$ presenting the Bimonster

The Monster has 194 conjugacy classes, and so that number of irreducible representations. Its character table (and much other useful information) is given in the Atlas [**22**], where we also find analogous data for the other simple groups of 'small' order. For example, we find that $\mathbb{M}$ has exactly 2, 3, 4 conjugacy classes of elements of order 2, 3, 4, respectively — these classes are named 2A, 2B, 3A, etc. We also find that the dimensions of the smallest irreducible representations of $\mathbb{M}$ are 1, 196883, 21296876, and 842609326. This is the same 196883 as on the right side of (1.1), and as the dimension of the Griess algebra.

2.2. The j-function. The group $\mathrm{SL}_2(\mathbb{R})$, consisting of 2×2 matrices of determinant 1 with real entries, acts on the upper half-plane $\mathbb{H} := \{\tau \in \mathbb{C} \,|\, \mathrm{Im}(\tau) > 0\}$ by fractional linear transformations

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} . \tau = \frac{a\tau + b}{c\tau + d} \ . \tag{2.3}$$

Of course this is really an action of $\mathrm{PSL}_2(\mathbb{R}) := \mathrm{SL}_2(\mathbb{R})/\{\pm I\}$ on $\mathbb{H}$, but it is more convenient to work with $\mathrm{SL}_2(\mathbb{R})$. $\mathbb{H}$ is the hyperbolic plane, one of the three possible geometries in two dimensions (the others are the sphere and the Euclidean plane), and $\mathrm{PSL}_2(\mathbb{R})$ is its group of orientation-preserving isometries.

Let G be a discrete subgroup of $\mathrm{SL}_2(\mathbb{R})$. Then the space $G\backslash\mathbb{H}$ has a natural structure of an orientable surface, and inherits a complex structure from $\mathbb{H}$ (so can be regarded as a complex curve). By the *genus* of the group G, we mean the genus of the resulting real surface $G\backslash\mathbb{H}$. For example, the choice $G = \mathrm{SL}_2(\mathbb{Z})$ yields the sphere with one puncture, so $\mathrm{SL}_2(\mathbb{Z})$ has genus 0. Moreover, any curve Σ with genus g and n punctures, for $3g+n > 3$, is equivalent as a complex curve to the space $G\backslash\mathbb{H}$, for some subgroup G of $\mathrm{SL}_2(\mathbb{R})$ isomorphic to the fundamental group $\pi_1(\Sigma)$.

The most important choice for G is $\mathrm{SL}_2(\mathbb{Z})$, thanks to its interpretation as the modular group of the torus. Most groups G of interest are commensurable with $\mathrm{SL}_2(\mathbb{Z})$, i.e. $G \cap \mathrm{SL}_2(\mathbb{Z})$ has finite index in both G and $\mathrm{SL}_2(\mathbb{Z})$. Examples of these are the congruence subgroups

$$\Gamma(N) := \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \mid \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \pmod{N} \} \ , \tag{2.4a}$$

$$\Gamma_0(N) := \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \mid N \text{ divides } c \} \ . \tag{2.4b}$$

For example $\Gamma_0(N)$ has genus 0 for $N = 2, 13, 25$, while $N = 50$ has genus 2 and $N = 24$ has genus 3. The following definition includes all groups arising in Monstrous Moonshine.

Definition 1. *Call a discrete subgroup G of $SL_2(\mathbb{R})$ a* moonshine-type modular group, *if it contains some $\Gamma_0(N)$, and also obeys the condition that*

$$\begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix} \in G \text{ iff } t \in \mathbb{Z} \ .$$

Such a modular group is necessarily commensurable with $\mathrm{SL}_2(\mathbb{Z})$. Note that for such a G, any meromorphic function $f : G\backslash\mathbb{H} \to \mathbb{C}$ will have a Fourier expansion of the form $f(\tau) = \sum_{n=-\infty}^{\infty} a_n q^n$, where $q = e^{2\pi \mathrm{i} \tau}$.

Definition 2. *Let G be any subgroup of $SL_2(\mathbb{R})$ commensurable with $SL_2(\mathbb{Z})$. By a* modular function f for G *we mean any meromorphic function $f : \mathbb{H} \to \mathbb{C}$, such that*

$$f(\frac{a\tau + b}{c\tau + d}) = f(\tau) \qquad \forall \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in G \tag{2.5}$$

and such that, for any $A \in \mathrm{SL}_2(\mathbb{Z})$, the function $f(A.\tau)$ has Fourier expansion of the form $\sum_{n=-\infty}^{\infty} b_n q^{n/N}$ for some N and b_n (both depending on A), and where $b_n = 0$ for all but finitely many negative n.

This definition simply states that f is a meromorphic function on the *compact* surface $\Sigma_G := G\backslash\overline{\mathbb{H}}$, where $\overline{\mathbb{H}} := \mathbb{H} \cup \mathbb{Q} \cup \{\mathrm{i}\infty\}$. The G-orbits of $\mathbb{Q} \cup \{\mathrm{i}\infty\}$ are called *cusps*; their role is to fill in the punctures of $G\backslash\mathbb{H}$, compactifying the surface, as there are much fewer meromorphic functions on compact surfaces than on noncompact ones (compare the Riemann sphere to the complex plane!).

We are especially interested in genus 0 groups G of moonshine-type. Their modular functions are particularly easy to characterise: there will be a unique modular function J_G for G, with q-expansion of the form

$$J_G(\tau) = q^{-1} + \sum_{n=1}^{\infty} a_n q^n \ ; \tag{2.6}$$

the modular functions for G are precisely the rational functions $f(\tau) = \frac{\mathrm{poly}(J_G(\tau))}{\mathrm{poly}(J_G(\tau))}$ in J_G. This function J_G is called the (normalised) *Hauptmodul* for the genus 0 group G. For example, the modular group $\mathrm{SL}_2(\mathbb{Z})$ has Hauptmodul

$$J_{\mathrm{SL}_2(\mathbb{Z})}(\tau) = J(\tau) = q^{-1} + 196884\, q + 214\,93760\, q^2 + 8642\,909970\, q^3 + \cdots \ . \tag{2.7}$$

This 196884 is the same as that on the left-side of (1.1). Historically, in place of this Hauptmodul was the equivalent

$$j(\tau)=\frac{(\theta_2(\tau)^8+\theta_3(\tau)^8+\theta_4(\tau)^8)^3}{8\eta(\tau)^{24}}=J(\tau)+744\ .$$

As we know, there are other genus 0 modular groups. For example the Hauptmoduls for $\Gamma_0(2)$, $\Gamma_0(13)$, and $\Gamma_0(25)$, are respectively

$$J_2(\tau)=q^{-1}+276q-2048q^2+11202q^3-49152q^4+184024q^5+\cdots\ , \qquad (2.8a)$$

$$J_{13}(\tau)=q^{-1}-q+2q^2+q^3+2q^4-2q^5-2q^7-2q^8+q^9+\cdots\ , \qquad (2.8b)$$

$$J_{25}(\tau)=q^{-1}-q+q^4+q^6-q^{11}-q^{14}+q^{21}+q^{24}-q^{26}+\cdots\ . \qquad (2.8c)$$

Thompson [**115**] proved there are only finitely many modular groups of moonshine-type in each genus. Cummins [**28**] has found all of these of genus 0 and 1. In particular there are precisely 6486 genus 0 moonshine-type groups. Exactly 616 of these have Hauptmoduls with rational (in fact integral) coefficients, the remainder have cyclotomic integer coefficients. There are some natural equivalences (e.g. a Galois action) which collapse this number to 371, 310 of which have integral Hauptmoduls.

In genus >0, two functions are needed to generate the function field. A complication facing the development of a higher-genus Moonshine is that, unlike the situation in genus 0 considered here, there is no canonical choice for these generators.

See e.g. [**92**] for a very readable account of some of the circle of ideas meandering through this subsection. Modular functions are discussed in e.g. [**75**].

3. The Monstrous Moonshine conjectures

The number on the left of (1.1) is the first nontrivial coefficient of the j-function, and the numbers on the right are the dimensions of the smallest irreducible representations of the Fischer–Griess Monster $\mathbb{M}$. On the one side we have a modular function; on the other, a sporadic finite simple group. Moonshine is the explanation and generalisation of this unlikely connection.

But first, why can't (1.1) merely be a coincidence? This is soon dispelled by comparing the next few coefficients of J with the dimensions of irreducible representations of $\mathbb{M}$:

$$214\,93760=212\,96876+196883+1\ , \qquad (3.1a)$$

$$8642\,99970=8426\,09326+212\,96876+2\cdot 196883+2\cdot 1\ . \qquad (3.1b)$$

3.1. The fundamental conjecture of Conway and Norton. The central structure in the attempt to understand equations (1.1) and (3.1) is an infinite-dimensional graded module for the Monster:

$$V=V_0\oplus V_1\oplus V_2\oplus V_3\oplus\cdots\ . \qquad (3.2a)$$

If we let ρ_d denote the d-dimensional irreducible representation of $\mathbb{M}$, then the first few subspaces will be $V_0=\rho_1$, $V_1=\{0\}$, $V_2=\rho_1\oplus\rho_{196883}$, and $V_3=\rho_1\oplus\rho_{196883}\oplus\rho_{21296876}$. This module is to have graded dimension

$$\dim_V(\tau)=\sum_{n=0} q^n\dim(V_n)=1+196884q^2+214\,93760q^3+\cdots=qJ(\tau)\ . \qquad (3.2b)$$

Of course, (3.2b) alone certainly doesn't uniquely determine V, but assume for now this V has been found. Thompson [**114**] suggested studying in addition the graded traces

$$T_g(\tau) := q^{-1} \sum_{n=0}^{\infty} \mathrm{ch}_{V_n}(g)\, q^n \tag{3.2c}$$

for all $g \in \mathbb{M}$, where the ch_{V_n} are characters. As taking $g = 1$ recovers J, (3.2c) is a natural twist of (3.2b). The functions T_g are now called the *McKay–Thompson series.*

Conway and Norton conjectured [**24**] that for each element g of the Monster $\mathbb{M}$, T_g is the Hauptmodul

$$J_{G_g}(\tau) = q^{-1} + \sum_{n=1}^{\infty} a_n(g)\, q^n \tag{3.3}$$

for a genus 0 subgroup G_g of $\mathrm{SL}_2(\mathbb{R})$. So for each n the coefficient $g \mapsto a_n(g)$ defines a character $\mathrm{ch}_{V_n}(g)$ of $\mathbb{M}$. They explicitly identify each of the groups G_g; these groups each contain $\Gamma_0(N)$ as a normal subgroup, for some N dividing $o(g) \gcd(24, o(g))$ ($o(g)$ is the order of g), and the quotient group $G_g/\Gamma_0(N)$ has exponent 2 (or 1).

Since $T_g = T_{hgh^{-1}}$ by definition, there are at most 194 distinct McKay–Thompson series. All coefficients $a_n(g)$ are integers (as are in fact most entries of the character table of $\mathbb{M}$). This implies that $T_g = T_h$ whenever the cyclic subgroups $\langle g\rangle$ and $\langle h\rangle$ are equal. In fact, the total number of distinct McKay–Thompson series T_g arising in Monstrous Moonshine turns out to be only 171. The first 50 coefficients $a_n(g)$ of each T_g are given in [**91**]. Together with the recursions given in §3.3 below, this allows one to effectively compute arbitrarily many coefficients $a_n(g)$ of the Hauptmoduls. It is also this which uniquely defines V, up to equivalence, as a graded $\mathbb{M}$-module.

For example, there are two different conjugacy classes of order 2 elements. One of these gives the Hauptmodul J_2 in (2.8a), while the other corresponds to (3.4) below. Similarly, (2.8b) corresponds to an order 13 element, but J_{25} in (2.8c) doesn't equal any T_g. Recall that there are exactly 616 Hauptmoduls of moonshine-type with integer coefficients, so most of these don't arise as T_g. Recently [**23**], a fairly simple characterisation has been found of the groups arising as G_g in Monstrous Moonshine. Their proof of this characterisation is by exhaustion.

Conway coined this conjecture *Monstrous Moonshine.* The word 'moonshine' here is English slang for 'insubstantial or unreal', 'idle talk or speculation', 'an illusive shadow'. It is meant to give the impression that matters here are dimly lit, and that [**24**] is 'distilling information illegally' from the character table of $\mathbb{M}$.

Monstrous Moonshine began, unofficially, in 1975 when Andrew Ogg remarked that the list of primes p for which the group

$$\Gamma_0(p)+ := \langle \Gamma_0(p), \frac{1}{\sqrt{p}} \begin{pmatrix} 0 & -1 \\ p & 0 \end{pmatrix} \rangle \tag{3.4}$$

has genus 0, is precisely equal to the list of primes p dividing the order of $\mathbb{M}$. Indeed, in the tables of [**24**] we find that, for each prime p dividing $|\mathbb{M}|$, an element g of $\mathbb{M}$ of order p is assigned the group $G_g = \Gamma_0(p)+$.

3.2. Lie theory and Moonshine. McKay not only noticed (1.1), but also observed that

$$j(\tau)^{\frac{1}{3}} = q^{-\frac{1}{3}} \left(1 + 248q + 4124q^2 + 34\,752q^3 + \cdots\right) . \tag{3.5}$$

The point is that 248 is the dimension of the defining representation of the E_8 Lie group, while $4124 = 3875 + 248 + 1$ and $34\,752 = 30\,380 + 3875 + 2 \cdot 248 + 1$. Incidentally, $j^{\frac{1}{3}}$ is a generating modular function for the genus-0 group $\Gamma(3)$. Thus Moonshine is related somehow to Lie theory.

McKay later found independent relationships with Lie theory [**89**], [**15**], [**47**], reminiscent of his famous A-D-E correspondence with finite subgroups of $\mathrm{SU}_2(\mathbb{C})$. As mentioned earlier, $\mathbb{M}$ has two conjugacy classes of involutions. Let K be the smaller one, called '2A' in [**22**] (the alternative, class '2B', has almost 100 million times more elements). The product of any two elements of K will lie in one of nine conjugacy classes: namely, 1A, 2A, 2B, 3A, 3C, 4A, 4B, 5A, 6A, corresponding respectively to elements of orders 1, 2, 2, 3, 3, 4, 4, 5, 6. It is surprising that, for such a complicated group as $\mathbb{M}$, that list stops at only 6 — we call $\mathbb{M}$ a *6-transposition group* for this reason (more on this in §5.2). The punchline: McKay noticed that those nine numbers are precisely the labels of the affine E_8 diagram (see Figure 2). Thus we can attach a conjugacy class of $\mathbb{M}$ to each vertex of the $\widehat{E}_8$ diagram. An interpretation of the *edges* in the $\widehat{E_8}$ diagram, in terms of $\mathbb{M}$, is unfortunately not known.

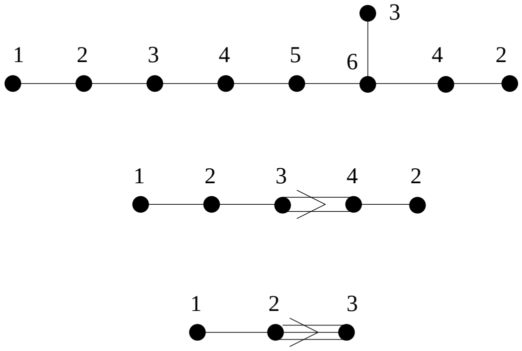

Figure 2. The affine E_8, F_4, and G_2 diagrams with labels

We can't get the affine E_7 labels in a similar way, but McKay noticed that an order two folding of affine E_7 gives the affine F_4 diagram, and we can obtain its labels using the Baby Monster $\mathbb{B}$ (the second largest sporadic). In particular, let K now be the smallest conjugacy class of involutions in $\mathbb{B}$ (also labelled '2A' in [**22**]); the conjugacy classes in KK have orders 1, 2, 2, 3, 4 ($\mathbb{B}$ is a 4-transposition group), and these are the labels of $\widehat{F_4}$. Of course we'd prefer $\widehat{E_7}$ to $\widehat{F_4}$, but perhaps that *two*-folding has something to do with the fact that an order-*two* central extension of $\mathbb{B}$ is the centraliser of an element $g \in \mathbb{M}$ of order *two*.

Now, the *triple*-folding of affine E_6 is affine G_2. The Monster has three conjugacy classes of order *three*. The smallest of these ('3A') has a centraliser which is a *triple* cover of the Fischer group $Fi'_{24}.2$. Taking the smallest conjugacy class of involutions in $Fi'_{24}.2$, and multiplying it by itself, gives conjugacy classes with orders 1, 2, 3 (hence $Fi'_{24}.2$ is a 3-transposition group) — and those not surprisingly are the labels of $\widehat{G_2}$!

Although we now understand (3.5) (see §4.1) and have proven the fundamental Conway–Norton conjecture (see §§4.2–4.4), McKay's $\widehat{E_8}, \widehat{F_4}, \widehat{G_2}$ observations still have no explanation. In [**47**] these patterns are extended, by relating various simple groups to the $\widehat{E_8}$ diagram with deleted nodes.

3.3. Replicable functions. There are several other less important conjectures. One which played an important role in ultimately proving the main conjecture involves the *replication formulae.* Conway–Norton want to think of the Hauptmoduls T_g as being intimately connected with $\mathbb{M}$; if so, then the group structure of $\mathbb{M}$ should somehow directly relate different T_g. Considering the power map $g \mapsto g^n$ leads to the following.

It was well-known classically that $j(\tau)$ has the property that $j(p\tau) + j(\frac{\tau}{p}) + j(\frac{\tau+1}{p}) + \cdots + j(\frac{\tau+p-1}{p})$ is a polynomial in $j(\tau)$, for any prime p (*proof:* it's a modular function for $\mathrm{SL}_2(\mathbb{Z})$, and hence equals a rational function of $j(\tau)$; since its only poles will be at the cusps, the denominator polynomial must be trivial). Hence the same will hold for J. More generally, we get

$$\sum_{ad=n, 0\le b<d} J(\frac{a\tau+b}{d}) = Q_n(J(\tau)) \ , \tag{3.6a}$$

where Q_n is the unique polynomial for which $Q_n(J(\tau)) - q^{-n}$ has a q-expansion with only strictly positive powers of q. For example, $Q_2(x) = x^2 - 2a_1$ and $Q_3(x) = x^3 - 3a_1 x - 3a_2$, where we write $J(\tau) = \sum_n a_n q^n$. The left side of (3.6a) is really a Hecke operator applied to J. These equations (3.6a) can be rewritten into recursions such as $a_4 = a_3 + (a_1^2 - a_1)/2$, or collected together into the remarkable expression (originally due to Zagier)

$$p^{-1} \prod_{\substack{m>0 \\ n\in\mathbb{Z}}} (1 - p^m q^n)^{a_{mn}} = J(z) - J(\tau) \ , \tag{3.6b}$$

where $p = e^{2\pi \mathrm{i} z}$.

Conway and Norton conjectured [**24**] that these formulas have an analogue for any McKay–Thompson series T_g. In particular, (3.6a) becomes

$$\sum_{ad=n, 0\le b<d} T_{g^a}(\frac{a\tau+b}{d}) = Q_{n,g}(T_g(\tau)) \ , \tag{3.7a}$$

where $Q_{n,g}$ plays the same role for T_g that Q_n played for J. These are called the replication formulae. Again, these yield recursions like $a_4(g) = a_2(g) + (a_1(g)^2 - a_1(g^2))/2$, or can be collected into the expression

$$p^{-1} \exp[-\sum_{k>0} \sum_{\substack{m>0 \\ n\in\mathbb{Z}}} a_{mn}(g^k) \frac{p^{mk} q^{nk}}{k}] = T_g(z) - T_g(\tau) \ . \tag{3.7b}$$

This looks a lot more complicated than (3.6b), but you can glimpse the Taylor expansion of $\ln(1 - p^m q^n)$ there and in fact for $g = 1$ (3.7b) reduces to (3.6b).

Axiomatising (3.7a) leads to Norton's notion of *replicable function* [**96**], [**1**]. Write $f^{(1)}(\tau) = q^{-1} + \sum_{k=1}^{\infty} b_k^{(1)} q^k$, and replacing each T_{g^a} in (3.7a) with $f^{(a)}$, use (3.7a) to recursively define each $f^{(n)}$. If each $f^{(n)}$ has a q-expansion of the form $f^{(n)}(\tau) = q^{-1} + \sum_{k=1}^{\infty} b_k^{(n)} q^k$ — i.e. no fractional powers of q arise — then we call $f = f^{(1)}$ replicable. Equation (3.7a) says the McKay–Thompson series are replicable, and [**30**] proved that the Hauptmodul of any genus 0 modular group of moonshine-type is replicable, provided its coefficients are rational. Conversely, Norton conjectured that any replicable function with rational coefficients is either such a Hauptmodul, or one of the 'modular fictions' $f(\tau) = q^{-1}$, $f(\tau) = q^{-1} \pm q$. This conjecture seems difficult and is still open. Incidentally, if the coefficients $b_k^{(1)}$ are irrational, then the definition (3.7a) of replicability should be modified to include Galois automorphisms (see §8 of [**29**]). Replication in positive genus is discussed in [**109**].

Replication (3.7a) concerns the power map $g \mapsto g^n$ in $\mathbb{M}$. Can Moonshine see more of the group structure of $\mathbb{M}$? We explored one step in this direction in §3.2, where McKay modeled products of conjugacy classes using Dynkin diagrams. A different idea is given in §5.1. It would be very desirable to find other direct connections between the group operation in $\mathbb{M}$ and e.g. the McKay–Thompson series.

3.4. The Leech lattice and Moonshine. The Leech lattice $\Lambda = \Lambda_{24}$ is a 24-dimensional even self-dual lattice [**26**] which is to lattices much as the $\mathbb{M}$-module V of (3.2a) turns out to be for vertex operator algebras (see §4.2 below). Λ has no vectors of odd norm, no norm-2 vectors, and precisely 196560 norm-4 vectors — a number remarkably close to the monstrous 196883. In fact its theta series $\Theta_\Lambda(\tau) = \sum_{v \in \Lambda} q^{v \cdot v/2}$, when divided by $\eta(\tau)^{24}$, equals $J(\tau) + 24$. Is this another example of Moonshine?

Indeed it is. However we have:

THEOREM 3. *Let $L \subset \mathbb{R}^n$ be any n-dimensional positive-definite lattice whose norms $\mathbf{v} \cdot \mathbf{v}$ are all rational. Let $\mathbf{t} \in \mathbb{R}^n$ be any vector with finite order in L: i.e. $m\mathbf{t} \in L$ for some nonzero $m \in \mathbb{Z}$. Then the theta series*

$$\Theta_{L+\mathbf{t}}(\tau) := \sum_{\mathbf{v} \in L} e^{\pi \mathrm{i} \tau \, (\mathbf{v}+\mathbf{t})^2} \ ,$$

divided by $\eta(\tau)^n$, is a modular function for some $\Gamma(N)$.

See e.g. Theorem 20 of [**100**] for a proof of this classical result. If L is in fact an *even* lattice (i.e. all norms $\mathbf{v} \cdot \mathbf{v}$ lie in $2\mathbb{Z}$), we can say more. Let $L^* := \{\mathbf{x} \in \mathbb{R}^n \mid \mathbf{x} \cdot L \subseteq \mathbb{Z}\}$ be the dual lattice. It contains L with finite index; write $\mathbf{t}_i + L$, $i = 1, \ldots, M$, for the finitely many cosets in L^*/L. Define a column vector $\vec{\chi}_L(\tau)$ with ith component $\Theta_{\mathbf{t}_i+L}(\tau)/\eta(\tau)^n$. Then $\vec{\chi}_L$ forms a *vector-valued modular function* for $\mathrm{SL}_2(\mathbb{Z})$: for any $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$,

$$\vec{\chi}_L\left(\frac{a\tau + b}{c\tau + d}\right) = \rho(A)\, \vec{\chi}_L(\tau) \tag{3.8}$$

for some M-dimensional unitary matrix representation ρ of $\mathrm{SL}_2(\mathbb{Z})$. In particular, for the Leech lattice $L = \Lambda$, $M = 1$ and we can quickly identify $\Theta_\Lambda(\tau)$ in terms of $J(\tau)$. Although the 196560 ≈ 196884 coincidence is thus trivial to explain, it will turn out to be a very instructive example of Moonshine.

The lattices are related to groups through their automorphism groups, which will always be finite for positive-definite lattices. The automorphism group $Co_0 := \mathrm{Aut}(\Lambda)$ of the Leech lattice has order about 8×10^{18}, and is the direct product of C_2 with Conway's sporadic group Co_1. Several other sporadics are also involved in $\mathrm{Aut}(\Lambda)$. To each automorphism $\alpha \in \mathrm{Aut}(\Lambda)$, let θ_α denote the theta series of the sublattice of Λ fixed by α. [**24**] also associate to each automorphism α a certain function $\eta_\alpha(\tau)$ of the form $\prod_i \eta(a_i\tau)/\prod_j \eta(b_j\tau)$ built out of the Dedekind eta. Both θ_α and η_α are constant on each conjugacy class in $\mathrm{Aut}(\Lambda)$, of which there are 202. [**24**] remarks that the ratio $\theta_\alpha/\eta_\alpha$ always seems to equal some McKay–Thompson series $T_{g(\alpha)}$. See also [**87**].

It turns out that this observation isn't quite correct [**74**]. For each $\alpha \in \mathrm{Aut}(\Lambda)$, the subgroup of $\mathrm{SL}_2(\mathbb{R})$ which fixes $\theta_\alpha/\eta_\alpha$ is indeed genus 0, but for exactly 15 conjugacy classes in $\mathrm{Aut}(\Lambda)$, $\theta_\alpha/\eta_\alpha$ is not the Hauptmodul.

Similarly, one can ask this for the E_8 lattice, whose automorphism group is the Weyl group (of order $\approx 7 \times 10^8$) of the E_8 Lie group. The automorphisms α of the E_8 lattice which yield a Hauptmodul were classified in [**19**].

4. Proof of the Monstrous Moonshine conjectures

At first glance, the significance of the Moonshine conjectures seems very unlikely: they constitute after all a finite set of very specialised coincidences. The whole point though is to try to understand *why* such seemingly incomparable objects as the Monster and the Hauptmoduls can be so related, and to try to extend and apply this understanding to other contexts. Establishing the truth (or falsity) of the conjectures was merely meant as an aid to uncovering the why of Moonshine. Indeed, in achieving this understanding, important new algebraic structures were formulated. We will sketch this theory below.

The main Conway–Norton conjecture was attacked almost immediately. Thompson showed [**113**] (see also [**103**]) that if $g \mapsto a_n(g)$ is a character for all sufficiently small n (apparently $n \leq 1300$ is sufficient), then it will be for all n. He also showed that if certain congruence conditions hold for a certain number of $a_n(g)$ (all with $n \leq 100$), then all $g \mapsto a_n(g)$ will be *virtual* characters (i.e. differences of true characters of $\mathbb{M}$). Atkin, Fong, and Smith (see [**110**] for details) used that to prove on a computer that indeed all $a_n(g)$ were virtual characters (they didn't quite reach $n = 1300$ though). But their work doesn't say anything more about the underlying (possibly virtual) representation V, other than its existence. Their work plays no role in the following.

We want to show that the McKay–Thompson series $T_g(\tau)$ of (3.2c) equals the Hauptmodul $J_{G_g}(\tau)$ in (3.3). First, we need to construct the infinite-dimensional module V of $\mathbb{M}$. We discuss this, and the underlying theory of vertex operator algebras, in §4.2. Borcherds' strategy [**11**] was to bring in Lie theory, by associating to the module V a 'Monster Lie algebra'. This algebra, and the underlying theory of generalised Kac–Moody algebras, is described in §4.3. In the final subsection we go from the Monster Lie algebra to the replication formulae, and conclude the proof. We begin this section though by explaining the much simpler connection of E_8 with $j^{\frac{1}{3}}$.

4.1. E_8 *and* $j^{\frac{1}{3}}$*.* An explanation for the relation between E_8 and $j^{\frac{1}{3}}$ was found almost immediately, by Kac and Lepowsky [**65**], [**76**]: $j^{\frac{1}{3}}$ is the (normalised) character of a representation of the affine Kac–Moody algebra $E_8^{(1)}$. Given a finite-dimensional simple Lie algebra $\mathfrak{g}$, the affine algebra $\mathfrak{g}^{(1)}$ is the infinite-dimensional Lie algebra consisting of all Laurent polynomials $\sum_{n=-\infty}^{\infty} a_n t^n$ where $a_n \in \mathfrak{g}$ and t is an indeterminate, together with a central term and derivation $D = -L_0$ (see [**66**], [**70**]). Highest weight representations are defined in the usual way. Thanks largely to the fact that the affine Weyl group is a semi-direct product of the additive group $\mathbb{Z}^r$ ($r = \mathrm{rank}(\mathfrak{g})$) with the finite Weyl group, the characters of these representations (especially the 'integrable' highest weight ones, which are the direct analogue of the finite-dimensional representations of $\mathfrak{g}$) transform nicely with respect to $\mathrm{SL}_2(\mathbb{Z})$. See e.g. Chapter 13 of [**70**] for details. This is probably the single biggest reason Kac–Moody algebras are so well-known.

THEOREM 4. [**69**] *Let $\mathfrak{g}$ be any finite-dimensional Lie algebra, and $\mathfrak{g}^{(1)}$ denote the corresponding affine algebra. Let P_+^k denote the finitely many 'level k integrable highest weight modules' L_λ of $\mathfrak{g}^{(1)}$. The $\mathfrak{g}^{(1)}$-module L_λ has a natural $\mathbb{Z}$-grading $L_\lambda = \oplus_{n=0}^{\infty} (L_\lambda)_n$ into finite-dimensional $\mathfrak{g}$-modules $(L_\lambda)_n$. Let $\chi_\lambda(\tau) = q^{h_\lambda - c/24} \sum_{n=0}^{\infty} \dim((L_\lambda)_n)\, q^n$ be the corresponding normalised character (for some appropriate choice of $h_\lambda - c/24 \in \mathbb{Q}$). Then each χ_λ is a holomorphic function in $\mathbb{H}$, and the vector $\vec{\chi}_k(\tau)$ with entry $\chi_\lambda(\tau)$ for each $\lambda \in P_+^k$ defines a vector-valued modular function for $SL_2(\mathbb{Z})$, as in (3.8), for some finite-dimensional unitary representation ρ of $SL_2(\mathbb{Z})$.*

In fact each character χ_λ will be a rational function in lattice theta series, and so will be a modular function for some $\Gamma(N)$. It turns out that there is only one level 1 integrable highest-weight representation of $E_8^{(1)}$, and its character equals $j^{\frac{1}{3}}$. The modularity of $j^{\frac{1}{3}}$ is thus predicted by Kac–Moody theory, and the fact that the coefficients are dimensions of E_8 representations is automatic. We will see a simultaneous generalisation of Theorems 3 and 4 next section.

We've already encountered the mysterious normalisation q^{-1} of the McKay–Thompson series, and the $q^{-\frac{1}{3}}$ of the $E_8^{(1)}$ character, and more generally the $q^{h_\lambda - c/24}$ of χ_λ. Many explanations have been provided for this pervasive factor. For example, to [**2**] it is topological in origin, and related to the Atiyah–Singer Index Theorem; a geometric interpretation using determinant line bundles is due to Segal [**107**]. In quantum physics it's called the *conformal anomaly* (a breakdown of manifest conformal symmetry when the classical system is quantised), and is introduced in regularisation as a vacuum energy. Probably the simplest instance of it is the prefactor in the familiar definition $\eta(\tau) = q^{\frac{1}{24}} \prod_{n=1}^{\infty}(1-q^n)$ for the Dedekind eta: reading through classical proofs for its modularity we find that '$\frac{1}{24}$' here arises through the combination $\zeta(2)/(2\pi)^2$; η appears also in physics in the partition function of the bosonic string, and that same '$\frac{1}{24}$' arises there via regularisation as $-\zeta(-1)/2$. The equivalence of these two expressions for $\frac{1}{24}$ comes from the functional equation of the Riemann zeta. This same zeta value appears famously in the central term of the Virasoro algebra (4.3), and Bloch [**8**] found other zeta values appearing in other algebras of differential operators, many of which have now been interpreted and generalised (starting with [**77**]) within the vertex operator algebra framework.

Although a direct explanation for Monstrous Moonshine using affine algebras has never been found (and certainly isn't expected), the theory of Kac–Moody algebras influenced every stage of the ultimate proof. For this reason we'll briefly sketch their theory. A simple finite-dimensional Lie algebra $\mathfrak{g}$ is built out of the 3-dimensional algebra sl_2, in a simple way; the Dynkin diagram of $\mathfrak{g}$ encodes the exact presentation. In the identical way, Kac–Moody algebras are also built out of copies of sl_2 — the only difference is that the finite-dimensionality constraint (a positive-definiteness condition on the Cartan matrix) is lifted. Their structure is completely analogous to that of the simple Lie algebras: e.g. it has a grading by roots into finite-dimensional spaces; it has a triangular decomposition (making Verma modules possible); it has an invariant symmetric bilinear form. See e.g. [**66**], [**70**] for details. The affine algebras are the class of Kac–Moody algebras especially analogous to the finite-dimensional ones.

4.2. The Moonshine module $V^\natural$. A vital component of the Monstrous Moonshine conjectures came a few years after [**24**]. In a deep work, Frenkel–Lepowsky–Meurman [**43**], [**44**] constructed a graded infinite-dimensional representation $V^\natural$ of $\mathbb{M}$ and conjectured (correctly) that it is the representation V in (3.2a). $V^\natural$ has a very rich algebraic structure: it is in fact a *vertex operator algebra!*

A vertex operator algebra [**9**], [**44**], [**67**], [**39**], [**79**] is an infinite-dimensional vector space V with infinitely many heavily constrained bilinear products $u *_n v$. The name means 'algebra of (generalised) vertex operators'; vertex operators are formal differential operators which originally appeared in physics as quantum fields describing the creation and propagation of physical strings (see §6 below), and were constructed later but independently by Lie theorists (starting with Lepowsky and Wilson) to realise affine Kac–Moody algebras as algebras of differential operators. Because there were vertex operator constructions associated to lattices, affine algebra modules, and string theory, and all of these have connections to modular functions, it was natural to use vertex operators to try to construct the $\mathbb{M}$-module V of (3.2a).

The definition of vertex operator algebra (VOA) is too complicated to give in detail here. A VOA is a graded infinite-dimensional vector space $\mathcal{V} = \oplus_{n=0}^{\infty}\mathcal{V}_n$, where each $\mathcal{V}_n$ is finite-dimensional. To simplify the discussion, we will limit ourselves in this paper to VOAs with one-dimensional $\mathcal{V}_0$, which is typical of the examples relevant to Moonshine (and conformal field theory). To each vector $v \in \mathcal{V}$ we assign a *vertex operator* $Y(v,z)$, which is a formal power series $Y(v,z) = \sum_{m\in\mathbb{Z}} v_{(m)} z^{-m-1}$, with coefficients $v_{(m)} \in \mathrm{End}(\mathcal{V})$. The vertex operator is just the generating function for the products: $u *_n v = u_{(n)}(v)$. These products respect the grading — in particular,

$$\mathcal{V}_k *_n \mathcal{V}_\ell \subseteq \mathcal{V}_{k+\ell-n-1} \ . \tag{4.1}$$

A key axiom, which collects together all the identities obeyed by the products $u *_n v$, can be written as

$$(z-w)^M [Y(u,z), Y(v,w)] = 0 \qquad \forall u, v \in \mathcal{V} \ , \tag{4.2a}$$

for some integer M (depending on u, v), where the bracket in (4.2a) means the commutator $Y(u,z)\,Y(v,w) - Y(v,w)\,Y(u,z)$. This strange-looking formula really says that each such commutator is a linear combination of Dirac deltas and their derivatives, all centred at $z = w$ (see e.g. Corollary 2.2 in [**67**]). Equation (4.2a) implies more down-to-earth identities, such as

$$(u_\ell v)_n = \sum_{i\geq 0}(-1)^i \binom{\ell}{i} \left(u_{\ell-i}\circ v_{n+i} - (-1)^\ell v_{\ell+n-i}\circ u_i\right) \ . \tag{4.2b}$$

There are two distinguished elements in $\mathcal{V}$: the identity $\mathbf{1}\in\mathcal{V}_0$ (so $\mathcal{V}_0=\mathbb{C}\mathbf{1}$) and the *conformal vector* $\omega\in\mathcal{V}_2$. The identity obeys $Y(\mathbf{1},z)=id$, i.e. $\mathbf{1}_{(n)}v=\delta_{n,-1}v$. More interesting is the conformal vector: writing $L_n=\omega_{(n+1)}$, the operators L_n are required to form a representation on $\mathcal{V}$ of the *Virasoro algebra*:

$$[L_m,L_n]=(m-n)L_{m+n}+\delta_{m,-n}\frac{m^3-m}{12}c\,id_{\mathcal{V}} \ , \tag{4.3}$$

for some number $c\in\mathbb{R}$ (an important numerical invariant of $\mathcal{V}$) called the *rank* or *central charge* of the VOA. In addition we require $L_0u=nu$ whenever $u\in\mathcal{V}_n$, and L_{-1} acts on $\mathcal{V}$ as a derivation.

The appearance here of the Virasoro algebra is fundamental. It is the unique nontrivial central extension of the (polynomial) vector fields on S^1, which in turn is the Lie algebra associated to the group Diff(S^1) of diffeomorphisms of the circle.

The notion of a VOA may seem very arbitrary, but as we'll mention in §6 it is the 'chiral algebra' of a conformal field theory. The simplest (and least interesting) special case of a VOA occurs when $M=0$ in (4.2a) — i.e. when all vertex operators commute. Then it is not hard to see that, for each choice of $z\neq 0$, $\mathcal{V}$ would be a commutative associative algebra with unit, whose product is given by $u *_z v := Y(u,z)v$. A more honest way to motivate VOAs has been suggested by Huang: binary trees can be used to keep track of the brackets in nested products, e.g. $a((bc)d)$, and e.g. Lie algebras can be easily formulated using this language [**58**]; in a monumental work [**59**], Huang 'two-dimensionalised' this Lie algebra formulation by replacing binary trees with spheres with tubes, and showed that the result is equivalent to a VOA.

A relation between VOAs and Lie algebras also exists at a more elementary level. Placing $\ell=n=0$ in (4.2b), and evaluating it on the right by $w\in\mathcal{V}$, gives

$$(u_0v)_0w=u_0(v_0w)-v_0(u_0w) \ . \tag{4.4}$$

Writing $[xy]$ for x_0y, this becomes the Lie algebra Jacobi identity, at least when $[xy]=-[yx]$. There are different ways to obtain from this a true Lie algebra. The simplest is that V_1 will be a Lie algebra for that bracket; moreover, the number $\langle u,v\rangle$ defined by $u_1v=\langle u,v\rangle\mathbf{1}$ is an invariant bilinear form for this Lie algebra (by (4.2b) with $\ell=0,n=1$). Equation (4.4) tells us each $\mathcal{V}_n$ is a $\mathcal{V}_1$-module, and in fact e^u will be an automorphism of $\mathcal{V}$ for any $u\in\mathcal{V}_1$. In the most common examples, $\mathcal{V}_1$ will be reductive (i.e. a direct sum of simple and abelian Lie algebras).

Modules M of $\mathcal{V}$ can be defined in the obvious way [**42**], [**79**] — e.g. for each $u\in\mathcal{V}$, each $u_{(n)}$ will be in End(M). All (irreducible) modules M come with a $\mathbb{Z}$-grading $M=\oplus_{n=0}^\infty M_n$, where $u_kM_n\subseteq M_{n+\ell-k-1}$ for all $u\in\mathcal{V}_\ell$, and $L_0x=(n+h)x$ for any $x\in M_n$, where h is some number (the *conformal weight*) depending only on M. The (normalised) character of M is

$$\chi_M(\tau)=q^{-c/24}\mathrm{Tr}_Mq^{L_0}=q^{h-c/24}\sum_{n=0}^\infty \dim(M_n)\,q^n \ .$$

It takes a little effort to construct even the simplest examples of VOAs. The best-behaved ones are called *rational VOAs* [**124**] (borrowing on terminology from physics) and have only finitely many irreducible modules. A rational VOA is associated to any even positive-definite lattice L, and their modules are in one-to-one correspondence with the cosets L^*/L. Another important example: to any affine nontwisted Kac–Moody algebra and choice of positive integer k (the 'level'), the highest weight module $L_{k\Lambda_0}$ has a natural VOA structure, and its modules are precisely the affine algebra modules L_λ for each highest weight $\lambda \in P_+^k$.

One of the deepest results in the theory of VOAs is due to Zhu:

Theorem 5. [**124**] *Let $\mathcal{V}$ be a rational VOA. Its characters $\chi_M(\tau)$ are holomorphic in $\mathbb{H}$, and the subspaces M_n carry representations for Aut($\mathcal{V}$). Write $\vec{\chi}_{\mathcal{V}}(\tau)$ for the vector whose components are the characters $\chi_M(\tau)$ of irreducible modules M. Then $\vec{\chi}_{\mathcal{V}}$ is a vector-valued modular function for $SL_2(\mathbb{Z})$.*

It is believed that the characters $\chi_M(\tau)$ themselves will be modular functions for some $\Gamma(N)$; significant progress towards this was made in [**5**] (see also [**71**]). The proof of Zhu's Theorem is much more difficult than that of Theorem 4, which it generalises.

The automorphism group $\mathrm{Aut}(\mathcal{V})$ is by definition required to fix ω, which is why it respects the grading of $\mathcal{V}$. $\mathrm{Aut}(\mathcal{V})$ is how group theory impinges on VOA theory. Since the automorphism group $\mathrm{Aut}(\mathcal{V})$ of a VOA contains $e^{\mathcal{V}_1}$ as a (normal) subgroup, $\mathrm{Aut}(\mathcal{V})$ can be finite only when $\mathcal{V}_1 = 0$. Zhu's Theorem tells us that Moonshine (without the genus-0 aspect) will hold between the group $\mathrm{Aut}(\mathcal{V})$ and the functions $\chi_M(\tau)$, for any rational VOA.

The most famous example of a VOA is the Moonshine module $V^\natural$ of [**44**]. It is the orbifold of the Leech lattice VOA $\mathcal{V}_\Lambda$ by the ±1-symmetry of Λ, which means it's the direct sum of two parts: an invariant part $V_+^\natural$ and a twisted part $V_-^\natural$ (more on this in §5.1). The orbifold serves two purposes: it removes the constant term '24' from the graded dimension $J + 24$ (hence the subspace $(\mathcal{V}_\Lambda)_1$) of $\mathcal{V}_\Lambda$; and it enhances the symmetry from the discrete part of $\mathrm{Aut}(\mathcal{V}_\Lambda)$, which is an extension of Co_0 by $(C_2)^{24}$, to all of $\mathbb{M}$.

A major claim of [**44**] was that $V^\natural$ is a 'natural' structure (hence their notation). Even so, this bipartite structure to $V^\natural$ complicates its study. We have $V_0^\natural = \mathbb{C}\mathbf{1}$, as usual, but the Lie algebra $\mathcal{V}_1 = \{0\}$ is trivial. For any such VOA, the space $\mathcal{V}_2$ will be a commutative nonassociative algebra with product $u \times v := u_1 v$ and identity $\frac{1}{2}\omega$. For the Moonshine VOA $V^\natural$, this can be shown (with effort!) to be the 196883-dimensional Griess algebra extended by an identity element. From this, we find the automorphism group of $V^\natural$ to be the Monster $\mathbb{M}$. The only irreducible module for $V^\natural$ is itself — such a VOA is called *holomorphic*. Together with Zhu's Theorem, this implies that its character, namely $J(\tau)$, must be a modular function for $\mathrm{SL}_2(\mathbb{Z})$ (strictly speaking, we only get invariance up to a 1-dimensional character of $\mathrm{SL}_2(\mathbb{Z})$, but it is easy to show that character must be identically 1). We'll see in §5.1 how to obtain the other McKay–Thompson series from $V^\natural$.

Conjecturally, there are 71 holomorphic VOAs with rank $c = 24$ [**106**]. Much as the Leech lattice is the unique even self-dual positive-definite lattice of dimension 24 containing no norm-2 vectors [**26**], the Moonshine module $V^\natural$ is *conjecturally* [**44**] the unique holomorphic VOA with $c = 24$ and with trivial $\mathcal{V}_1$. Thus, just as the Leech lattice is the unique lattice with theta series Θ_Λ, so (conjecturally) is the Moonshine module the unique holomorphic VOA with (normalised) graded dimension J. Proving this is one of the most important (and difficult) challenges in the subject.

4.3. The Monster Lie algebra $\mathfrak{m}$. To show that all of the McKay–Thompson series T_g are indeed Hauptmoduls, Borcherds needed identities satisfied by their q-expansions. He obtained these through a Lie algebra he associated to $V^\natural$. Before discussing it, let's briefly describe Borcherds' generalisation of Kac–Moody algebras [**10**].

A Borcherds–Kac–Moody algebra differs from a Kac–Moody algebra in that it is built up from Heisenberg algebras as well as sl_2, and these subalgebras intertwine in more complicated ways. Nevertheless much of the theory for finite-dimensional simple Lie algebras continues to find an analogue in this much more general setting (e.g. root-space decomposition, Weyl group, character formula,...). This unexpected fact is the point of Borcherds–Kac–Moody algebras. For reasons of space we avoid giving here the fairly simple definition, but for this and much more see the review articles [**53**], [**63**], [**102**].

Their basic structure theorem is that of Kac–Moody algebras. In particular, there is a grading by roots into finite-dimensional spaces (except that the 0-graded piece, corresponding to the Cartan subalgebra, may be infinite-dimensional). They also have a triangularisable decomposition and an invariant symmetric bilinear form. Indeed, these structural properties *characterise* Borcherds–Kac–Moody algebras. In this sense Borcherds–Kac–Moody algebras are the ultimate generalisation of simple Lie algebras, in that any further generalisation would lose some basic structural ingredient.

In short, Borcherds' algebras strongly resemble the Kac–Moody ones and constitute a natural and nontrivial generalization. The main differences are that they can be generated by copies of the 3-dimensional Heisenberg algebra as well as sl_2, and that there can be imaginary simple roots. Borcherds introduced these algebras and developed their theory in order to understand the Monster Lie algebra $\mathfrak{m}$.

We want to construct $\mathfrak{m}$ from the Moonshine module $V^\natural = V_0^\natural \oplus V_1^\natural \oplus \cdots$. For later convenience, relabel its subspaces $V^i := V_{i+1}^\natural$. Of course the obvious choice $V_1^\natural = V^0$ is 0-dimensional, so we must modify $V^\natural$ first. Let $II_{1,1}$ denote the even self-dual indefinite lattice consisting of all pairs $(m,n) \in \mathbb{Z}^2$ with inner product $(m,n)\cdot(m',n') = mn' + nm'$. Because it is indefinite, the usual construction of a VOA from a lattice will fail here to produce a true VOA, but most properties will be obtained. Call this near-VOA, $\mathcal{V}_{1,1}$.

The Monster Lie algebra $\mathfrak{m}$ is a Lie algebra associated to the near-VOA $V^\natural \otimes \mathcal{V}_{1,1}$ — see [**11**] for the details. $\mathfrak{m}$ inherits a $II_{1,1}$-grading from $\mathcal{V}_{1,1}$, and this is its root space decomposition: the (m,n) root space is isomorphic (as a vector space) to V^{mn}, if $(m,n) \neq (0,0)$; the $(0,0)$ piece is isomorphic to $\mathbb{R}^2$. Structurally, the Monster Lie algebra has a decomposition $\mathfrak{m} = u^+ \oplus \mathrm{gl}_2 \oplus u^-$ into a sum of Lie subalgebras, where $u^\pm$ are free Lie algebras (see e.g. [**64**]). It inherits the action of $\mathbb{M}$ from $V^\natural$.

This construction of $\mathfrak{m}$ may seem indirect; an alternate approach, anticipated in [**11**] and [**12**], uses *Moonshine cohomology* [**81**] — a functor, inspired by BRST cohomology in conformal field theory, assigning to certain $c = 2$ near-VOAs some Lie algebra carrying an action of $\mathbb{M}$. To $\mathcal{V}_{1,1}$ this functor associates $\mathfrak{m}$.

4.4. Denominator identities and modular equations. It was discovered early on that the Hauptmoduls all obey the replication formulae, and that anything obeying those formulae will be determined by their first few coefficients. The idea then is to show that the McKay–Thompson series T_g of (3.2c) also are replicable. Borcherds did this using Lie algebra denominator identities [**11**].

Finite-dimensional simple Lie algebras $\mathfrak{g}$ possess a very useful formula for their characters, due to Weyl: the (formal) character χ_λ of a module L_λ equals

$$\chi_\lambda := \sum_\mu \dim(L_\lambda(\mu))\, e^\mu = e^{-\rho}\,\frac{\sum_{w\in W}\epsilon(w)\, e^{w(\lambda+\rho)}}{\prod_{\alpha\in\Delta_+}(1-e^{-\alpha})}\ , \tag{4.5}$$

where W is the Weyl group, Δ_+ the positive roots, $\epsilon(w) = \det(w)$ is a sign, and where $\oplus_\mu L_\lambda(\mu)$ is the weight-space decomposition of L_λ. As the weights μ by definition lie in the dual $\mathfrak{h}^*$ of the Cartan subalgebra of $\mathfrak{g}$, the character χ_λ can be regarded as a complex-valued function on the space $\mathfrak{h} \cong \mathbb{C}^r$ ($r = \mathrm{rank}(\mathfrak{g})$).

Consider the trivial representation: i.e. $x \mapsto 0$ for all $x \in \mathfrak{g}$. Its character χ_0 will be identically 1. Thus the character formula (4.5) tells us that a certain alternating sum over a Weyl group, equals a certain product over positive roots. These formulas, called *denominator identities*, are nontrivial even in this finite-dimensional case.

In a famous paper [**83**], Macdonald generalised the denominator identity for (4.5), to infinite sum/product identities, corresponding to the extended Dynkin diagrams. The simplest one was known classically as the Jacobi triple product identity:

$$\sum_{n=-\infty}^{\infty}(-1)^n x^{n^2} y^n = \prod_{m=1}^{\infty}(1-x^{2m})(1-x^{2m-1}y)(1-x^{2m-1}y^{-1})\ . \tag{4.6}$$

Macdonald's identities were later reinterpreted, by Kac and Moody, as denominator identities for the affine algebras. For example, we now know (4.6) to be the denominator identity for the algebra $A_1^{(1)}$.

In particular, the same formula (4.5) holds for Kac–Moody algebras, except that the sum and product are now infinite, the positive roots now come with multiplicities, and the characters are usually normalised by a prefactor $q^{h_\lambda - c/24}$. The variable τ in Theorem 4 is one of the coordinates in the Cartan subalgebra $\mathbb{C}^{r+2}$ of the affine algebra (see e.g. equation (13.2.4) of [**66**]). In that theorem we dropped the remaining variable dependence of the χ_λ for readability, although those additional coordinates serve the important role of guaranteeing linear independence of the characters, and of giving us an action of $\mathrm{SL}_2(\mathbb{Z})$ rather than merely $\mathrm{PSL}_2(\mathbb{Z})$.

Because a Borcherds–Kac–Moody algebra $\mathfrak{g}$ is triangularisable, highest weight $\mathfrak{g}$-modules can be defined in the usual way from Verma modules. The character formula becomes

$$\chi_\lambda = e^{-\rho}\,\frac{\sum_{w\in W}\epsilon(w)\, w(e^{\lambda+\rho}S_\lambda)}{\prod_{\alpha\in\Delta_+}(1-e^{-\alpha})^{\mathrm{mult}\,\alpha}}\ , \tag{4.7}$$

where S_λ is a correction factor due to imaginary simple roots.

The corresponding denominator identity of the Monster Lie algebra $\mathfrak{m}$ can be computed, and is given in (3.6b). Its Weyl group is C_2 and sends the (m, n)-root space to

(n,m); the (m,n) root has multiplicity given by coefficient a_{mn} of J; for each $n>0$ we have an imaginary simple root $(1,n)$ with multiplicity a_n. Because of a cohomological interpretation of all denominator identities, (3.6b) can be 'twisted' by each $g\in\mathbb{M}$, and this gives (3.7b). These formulas are equivalent to the replication formula (3.7a) conjectured in §3.3.

Identities equivalent to (3.7b) were obtained by more elementary means — i.e. methods requiring less of the theory of Borcherds–Kac–Moody algebras — in [**64**] and [**68**], permitting a simplification of Borcherds' proof at this stage.

Now, it turns out that if we verify for each conjugacy class K_g of $\mathbb{M}$ that the first, second, third, fourth and sixth coefficients of the McKay–Thompson series T_g and the corresponding Hauptmodul J_{G_g} agree, then indeed $T_g=J_{G_g}$. That is precisely what Borcherds then did: he compared finitely many coefficients, and as they all equalled what they should, this concluded the proof [**11**] of Monstrous Moonshine!

However, this case-by-case verification occurred at the critical point where the McKay–Thompson series were being compared directly to the Hauptmoduls, and so provides little insight into why the T_g are genus 0. Fortunately a more conceptual explanation of their equality has since been found.

A function f obeying the replication formulae (3.7a) will also obey *modular equations* — i.e. a 2-variable polynomial identity satisfied by $f(x)$ and $f(nx)$. The simplest examples come from the exponential and cosine functions: note that for any $n>0$, $\exp(nx)=(\exp(x))^n$ and $\cos(nx)=T_n(\cos(x))$ where T_n is a Tchebychev polynomial. It was known classically that j (hence J) satisfied a modular equation for any n: e.g. put $X=J(\tau)$ and $Y=J(2\tau)$, then

$$\begin{aligned}(X^2-Y)(Y^2-X)=&\,393768\,(X^2+Y^2)+42987520\,XY+40491318744\,(X+Y)\\&-120981708338256\ .\end{aligned}$$

The only functions $f(\tau)=q^{-1}+a_1q+\cdots$ which obey modular equations for all n, are $J(\tau)$ and the 'modular fictions' q^{-1} and $q^{-1}\pm q$ (which are essentially exp, cos, and sin) [**72**]. More generally, we have:

THEOREM 6. [**29**] *A function $B(\tau)=q^{-1}+\sum_{n=1}^{\infty}b_nq^n$ which obeys a modular equation for all $n\equiv 1$ (mod N), will either be of the form $B(\tau)=q^{-1}+b_1q$, or will be a Hauptmodul for a modular group of moonshine-type.*

The converse is also true [**29**]. The denominator identity argument tells us each T_g obeys a modular equation for each $n\equiv 1$ modulo the order of g, so Theorem 6 then concludes the proof of Monstrous Moonshine.

The computer searches in [**20**] suggest that the hypothesis of Theorem 6 may be considerably weakened, perhaps all the way down to the existence of modular equations for any two distinct primes.

5. Further developments

5.1. Orbifolds. About a third of the McKay–Thompson series T_g will have some negative coefficients. In §5.4 we'll see Borcherds interpret them as dimensions of superspaces (which come with signs). In an important announcement [**97**], on par with [**24**], Norton proposed that, although $T_g(-1/\tau)$ will not usually be another McKay–Thompson series, it will always have nonnegative integer q-coefficients, and these can be interpreted as ordinary dimensions. In the process, he extended the $g \mapsto T_g$ assignment to commuting pairs $(g,h) \in \mathbb{M} \times \mathbb{M}$.

In particular, to each such pair we have a function $N(g,h;\tau)$, which we will call a *Norton series*, such that

$$N(g^a h^c, g^b h^d; \tau) = \alpha\, N(g,h;\frac{a\tau+b}{c\tau+d}) \qquad \forall \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \ , \tag{5.1}$$

for some root of unity α (of order dividing 24, and depending on g, h, a, b, c, d). The Norton series $N(g,h;\tau)$ is either constant, or generates the modular functions for a genus-0 subgroup of $\mathrm{SL}_2(\mathbb{Z})$ containing some $\Gamma(N)$ (but otherwise not necessarily of moonshine-type). Constant $N(g,h;\tau)$ arise when all elements of the form $g^a h^b$ (for $\gcd(a,b) = 1$) are 'non-Fricke' (an element $g \in \mathbb{M}$ is called *Fricke* if the group G_g contains an element sending 0 to $\mathrm{i}\infty$ — the identity 1 is Fricke, as are 120 of the 171 G_g). Each $N(g,h;\tau)$ has a $q^{\frac{1}{N}}$-expansion for that N; the coefficients of this expansion are characters evaluated at h of some central extension of the centralizer $C_{\mathbb{M}}(g)$. Simultaneous conjugation of g, h leaves the Norton series unchanged: $N(aga^{-1}, aha^{-1};\tau) = N(g,h;\tau)$.

For example, when $\langle g,h\rangle \cong C_2 \times C_2$ and g, h, gh are all in class 2A, then $N(g,h;\tau) = \sqrt{J(\tau) - 984}$. The McKay–Thompson series are recovered by the $g = 1$ specialisation: $N(1,h;\tau) = T_h(\tau)$. This action (5.1) of $\mathrm{SL}_2(\mathbb{Z})$ is related to its natural action on the fundamental group $\mathbb{Z}^2$ of the torus, as we'll see in §6, as well as a natural action of the braid group, as we'll see next subsection. Norton arrived at his conjecture empirically, by studying the data of Queen (see §5.3).

The basic tool we have for approaching Moonshine conjectures is the theory of VOAs, so we need to understand Norton's suggestion from that point of view. For reasons of space, we'll limit this discussion to $V^\natural$, but it generalises. Given any automorphism $g \in \mathrm{Aut}(V^\natural)$, we can define g-twisted modules in the obvious way [**36**]. Then for each $g \in \mathbb{M}$, there is a unique g-twisted module, call it $V^\natural(g)$, for $V^\natural$ — this statement generalises the holomorphicity of $V^\natural$ mentioned in §4.2. More generally, given any automorphism $h \in \mathrm{Aut}(V^\natural)$ commuting with g, h will yield an automorphism of $V^\natural(g)$, so we can perform Thompson's twist (3.2c) and write

$$q^{-c/24}\mathrm{Tr}_{V^\natural(g)} h\, q^{L_0} =: \mathcal{Z}(g,h;\tau) \ . \tag{5.2}$$

These $\mathcal{Z}(g,h)$'s can be thought of as the building blocks of the graded dimensions of various eigenspaces in $V^\natural(g)$: e.g. if h has order m, then the subspace of $V^\natural(g)$ fixed by automorphism h will have graded dimension $m^{-1}\sum_{i=1}^m \mathcal{Z}(g,h^i)$. In the case of the Monster considered here, we have $\mathcal{Z}(g,h) = N(g,h)$.

The important paper [**36**] proves that, whenever the subgroup $\langle g,h\rangle$ generated by g and h is cyclic, then $N(g,h)$ will be a Hauptmodul satisfying (5.1). One way this will happen of course is whenever the orders of g and h are coprime. Extending [**36**] to all commuting pairs g, h is one of the most pressing tasks in Moonshine.

This orbifold construction is the same as was used to construct $V^\natural$ from $\mathcal{V}_\Lambda$: $V^\natural$ is the sum of the 'ι'-invariant subspace $V^\natural_+$ of $\mathcal{V}_\Lambda$ with the 'ι'-invariant subspace $V^\natural_-$ of the unique '-1'-twisted module for $\mathcal{V}_\Lambda$, where $\iota \in \mathrm{Aut}(\Lambda)$ is some involution. The graded dimensions of $V^\natural_\pm$ are $2^{-1}(\mathcal{Z}(\pm 1, 1) + \mathcal{Z}(\pm 1, \iota))$, respectively, and these sum to J.

The orbifold construction is also involved in an interesting reformulation of the Hauptmodul property, due to Tuite [**116**]. Assume the uniqueness conjecture: $V^\natural$ is the only VOA with graded dimension J. He argues from this that, for each $g \in \mathbb{M}$, T_g will be a Hauptmodul iff the only orbifolds of $V^\natural$ are $\mathcal{V}_\Lambda$ and $V^\natural$ itself. In e.g. [**62**], this analysis is extended to some of Norton's $N(g,h)$'s, where the subgroup $\langle g, h\rangle$ is not cyclic (thus going beyond [**36**]), although again assuming the uniqueness conjecture.

5.2. Why the Monster? That $\mathbb{M}$ is associated with *modular functions* can be explained by it being the automorphism group of the Moonshine VOA $V^\natural$. But what is so special about this group $\mathbb{M}$ that these modular functions T_g and $N(g,h)$ should be Hauptmoduls? This is still open. One approach is due to Norton, and was first (rather cryptically) stated in [**97**]: the Monster is probably the largest (in a sense) group with the 6-transposition property. Recall from §3.2 that a k-transposition group G is one generated by a conjugacy class K of involutions, where the product gh of any two elements of K has order $\leq k$. For example, taking K to be the transpositions in the symmetric group $G = S_n$, we find that S_n is 3-transposition.

A transitive action of $\Gamma := \mathrm{PSL}_2(\mathbb{Z})$ on a finite set X with one distinguished point $x_0 \in X$, is equivalent to specifying a finite index subgroup Γ_0 of Γ. In particular, Γ_0 is the stabiliser $\{g \in \Gamma \mid g.x_0 = x_0\}$ of x_0, X can be identified with the cosets $\Gamma_0\backslash\Gamma$, and x_0 with the coset Γ_0. (If we avoid specifying x_0, then Γ_0 will be identified only up to conjugation.)

To such an action, we can associate an interesting triangulation of the closed surface $\Gamma_0\backslash\overline{\mathbb{H}}$, called a (modular) *quilt*. The definition, originally due to Norton and further developed by Parker, Conway, and Hsu, is somewhat involved and will be avoided here (but see especially Chapter 3 of [**57**]). It is so-named because there is a polygonal 'patch' covering every cusp of $\Gamma_0\backslash\mathbb{H}$, and the closed surface is formed by sewing together the patches along their edges ('seams'). There are a total of $2n$ triangles and n seams in the triangulation, where n is the index $\|\Gamma_0\backslash\Gamma\| = \|X\|$. The boundary of each patch has an even number of edges, namely the double of the corresponding cusp width. The familiar formula

$$\gamma = \frac{n}{12} - \frac{n_2}{4} - \frac{n_3}{3} - \frac{n_\infty}{2} + 1$$

for the genus γ of $\Gamma_0\backslash\mathbb{H}$ in terms of the index n and the numbers n_i of Γ_0-orbits of fixed-points of order i, can be interpreted in terms of the data of the quilt (see (6.2.3) of [**57**]), and we find in particular that if every patch of the quilt has at most 6 sides, then the genus will be 0 or 1, and genus 1 only exceptionally.

In particular, we're interested in one class of these Γ-actions (actually an $\mathrm{SL}_2(\mathbb{Z})$-action, but this doesn't matter). Recall that the braid group B_3 has presentation

$$\langle \sigma_1, \sigma_2 \mid \sigma_1\sigma_2\sigma_1 = \sigma_2\sigma_1\sigma_2\rangle \ , \tag{5.3a}$$

and centre $Z = \langle(\sigma_1\sigma_2\sigma_1)^2\rangle$ [**7**]. It is related to the modular group by

$$B_3/Z \cong \mathrm{PSL}_2(\mathbb{Z}) \ , \quad B_3/\langle(\sigma_1\sigma_2\sigma_1)^4\rangle \cong \mathrm{SL}_2(\mathbb{Z}) \ . \tag{5.3b}$$

Fix a finite group G (we're most interested in the choice $G = \mathbb{M}$). We can define a right action of B_3 on triples $(g_1, g_2, g_3) \in G^3$ by

$$(g_1, g_2, g_3)\sigma_1 = (g_1 g_2 g_1^{-1}, g_1, g_3) \ , \qquad (g_1, g_2, g_3)\sigma_2 = (g_1, g_2 g_3 g_2^{-1}, g_2) \ . \tag{5.4a}$$

We will be interested in this action on the subset of G^3 where all $g_i \in G$ are involutions. The action (5.4a) is equivalent to a reduced version, where we replace (g_1, g_2, g_3) with $(g_1 g_2, g_2 g_3) \in G^2$. Then (5.4a) becomes

$$(g, h)\sigma_1 = (g, gh) \ , \qquad (g, h)\sigma_2 = (gh^{-1}, h) \ . \tag{5.4b}$$

These B_3 actions come from specialisations of the Burau and reduced Burau representations [**7**], respectively, and generalise to actions of B_n on G^n and G^{n-1}. We can get an action of $\mathrm{SL}_2(\mathbb{Z})$ from the B_3 action (5.4b) in two ways: either

(i) by restricting to commuting pairs g, h; or

(ii) by identifying each pair (g, h) with all its conjugates (aga^{-1}, aha^{-1}).

Norton's $\mathrm{SL}_2(\mathbb{Z})$ action of §5.1 arises from the B_3 action (5.4b), when we perform both (i) and (ii).

The quilt picture was designed for this $\mathrm{SL}_2(\mathbb{Z})$ action. The point of this construction is that the number of sides in each patch is determined by the orders of the corresponding elements g, h. If G is say a 6-transposition group (such as the Monster), and we take the involutions g_i from 2A, then each patch will have ≤ 6 sides, and the corresponding genus will be 0 (usually) or 1 (exceptionally if at all). In this way we can relate the Monster with a genus-0 property.

Based on the actions (5.4), Norton anticipates some analogue of Moonshine valid for noncommuting pairs. CFT considerations ('higher genus orbifolds') alluded to in §6 suggest that more natural should be e.g. quadruples $(g, g', h, h') \in \mathbb{M}^4$ obeying $ghg^{-1}h^{-1} = h'g'h'^{-1}g'^{-1}$.

An interesting question is, how much does Monstrous Moonshine determine the Monster? How much of $\mathbb{M}$'s structure can be deduced from e.g. McKay's $\widehat{E}_8$ Dynkin diagram observation, and/or the (complete) replicability of the T_g, and/or Norton's conjectures in §5.1, and/or Modular Moonshine in §5.4 below? A small start toward this is taken in [**99**], where some control on the subgroups of $\mathbb{M}$ isomorphic to $C_p \times C_p$ (p prime) was obtained, using only the properties of the series $N(g, h)$. For related work, see Chapter 8 of [**57**].

5.3. Other finite groups. It is natural to ask about Moonshine for other groups. Indeed, the Hauptmodul for $\Gamma_0(2)+$ looks like

$$q^{-1} + 4372q + 96256q^2 + 12\,40002q^3 + \cdots \tag{5.5a}$$

and we find the relations

$$4372 = 4371 + 1 \ , \qquad 96256 = 96255 + 1 \ , \qquad 12\,40002 = 11\,39374 + 4371 + 2 \cdot 1 \ , \tag{5.5b}$$

where 1, 4371, 96255, and 11 39374 are all dimensions of irreducible representations of the Baby Monster $\mathbb{B}$. Thus we find Moonshine for $\mathbb{B}$! We will return to this example shortly.

Of course any subgroup of $\mathbb{M}$ automatically inherits Moonshine by restriction, but obviously this isn't interesting. Most constructions of the Leech lattice start with Mathieu's sporadic M_{24} (see e.g. Chapters 10 and 11 of [**26**]), and most constructions of the Monster involve the Leech lattice. Thus we are led to the following natural hierarchy of (most) sporadics:

(1) M_{24} (from which we can get M_{11}, M_{12}, M_{22}, M_{23}); which leads to
(2) $Co_0 = C_2 \times Co_1$ (from which we get HJ, HS, McL, Suz, Co_3, Co_2); which leads to
(3) $\mathbb{M}$ (from which we get He, Fi_{22}, Fi_{23}, Fi'_{24}, HN, Th, $\mathbb{B}$).

It can thus be argued that we could approach problems in Monstrous Moonshine, by first addressing in order M_{24} and Co_1, which should be much simpler. Indeed, the full VOA orbifold theory — i.e. the complete analogue of §5.1 — for M_{24} has been established in [**38**] (the relevant series $\mathcal{Z}(g,h)$ had already been constructed in [**88**]).

Largely by trial and error, Queen [**101**] established Moonshine for the following groups (all essentially centralisers of elements of $\mathbb{M}$): Co_0, Th, $3.2.Suz$, $2.HJ$, HN, $2.A_7$, He, M_{12} (by e.g. '$2.HJ$' we mean C_2 is normal and HJ is the quotient $2.HJ/C_2$). In particular, to each element g of these groups, there corresponds a series $Q_g(\tau) = q^{-1} + \sum_{n=0}^{\infty} a_n(g)q^n$, which is a Hauptmodul for some modular group of moonshine-type, and where each $g \mapsto a_n(g)$ is a virtual character. For Th, HN, He and M_{12} it is a proper character. Other differences with Monstrous Moonshine are that there can be a preferred nonzero value for the constant term a_0, and that although $\Gamma_0(N)$ will be a subgroup of the fixing group, it won't necessarily be normal. We will return to these results next section, where we will see that many seem to come out of the Moonshine for $\mathbb{M}$. About half of Queen's Hauptmoduls Q_g for Co_0 do not arise as a McKay–Thompson series for $\mathbb{M}$. Norton's conjectures in §5.1 are a reinterpretation and extension of Queen's work.

Queen never reached $\mathbb{B}$ because of its size. However, the Moonshine (5.5) for $\mathbb{B}$ falls into her and Norton's scheme because (5.5a) is the McKay–Thompson series associated to class 2A of $\mathbb{M}$, and the centraliser of an element in 2A is a double cover of $\mathbb{B}$.

There can't be a VOA $V = \oplus_n V_n$ with graded dimension (5.5a) and automorphisms in $\mathbb{B}$, because e.g. the $\mathbb{B}$-module V_3 doesn't contain V_2 as a submodule. However, Höhn deepened the analogy between $\mathbb{M}$ and $\mathbb{B}$ by constructing a vertex operator superalgebra $V\mathbb{B}^\natural$ of rank $c = 23.5$, called the *shorter Moonshine module*, closely related to $V^\natural$ (see e.g. [**56**]). Its automorphism group is $C_2 \times \mathbb{B}$. Just as $\mathbb{M}$ is the automorphism group of the Griess algebra $V_2^\natural$, so is $\mathbb{B}$ the automorphism group of the algebra $(V\mathbb{B}^\natural)_2$. Just as $V^\natural$ is associated to the Leech lattice Λ, so is $V\mathbb{B}^\natural$ associated to the shorter Leech lattice O_{23}, the unique 23-dimensional positive-definite self-dual lattice with no vectors of length 2 or 1 (see e.g. Chapter 6 of [**26**]). The automorphism group of O_{23} is $C_2 \times Co_2$.

There has been no interesting Moonshine rumoured for the remaining six sporadics (the *pariahs* J_1, J_3, Ru, ON, Ly, J_4). There will be some sort of Moonshine for any group which is an automorphism group of a vertex operator algebra (so this means any finite group [**37**]!). Many finite groups of Lie type should arise as automorphism groups of VOAs associated to affine algebras except defined over finite fields. But apparently all known examples of genus-0 Moonshine are limited to the groups involved with $\mathbb{M}$.

5.4. Modular Moonshine. Consider an element $g \in \mathbb{M}$. We expect from [**101**], [**97**], [**36**] that there is a Moonshine for the centraliser $C_{\mathbb{M}}(g)$ of g in $\mathbb{M}$, governed by the g-

twisted module $V^\natural(g)$. Unfortunately, $V^\natural(g)$ is not usually itself a VOA, so the analogy with $\mathbb{M}$ is not perfect. Ryba found it interesting that, for $g \in \mathbb{M}$ of prime order p, Norton's series $N(g,h)$ is a McKay–Thompson series (and has all the associated nice properties) whenever h is *p-regular* (i.e. h has order coprime to p). This special behaviour of p-regular elements suggested to him to look at modular representations.

The basics of modular representations and Brauer characters are discussed in sufficient detail in Chapter 2 of [**31**]. A *modular representation* ρ of a group G is a representation defined over a field of positive characteristic p dividing the order $|G|$ of G. Such representations possess many special (i.e. unpleasant) features. For one thing, they are no longer completely reducible (so the role of irreducible modules as direct summands will be replaced with their role as composition factors). For another, the usual notion of character (the trace of representation matrices) loses its usefulness and is replaced by the more subtle *Brauer character* $\beta(\rho)$: a complex-valued class function on $\mathbb{M}$ which is only well-defined on the p-regular elements of G.

THEOREM 7. [**105**], [**17**], [**13**] *Let $g \in \mathbb{M}$ be any element of prime order p, for any p dividing $|\mathbb{M}|$. Then there is a vertex operator superalgebra ${}^g\mathcal{V} = \oplus_{n\in\mathbb{Z}}{}^g\mathcal{V}_n$ defined over the finite field $\mathbb{F}_p$ and acted on by the centraliser $C_\mathbb{M}(g)$. If $h \in C_\mathbb{M}(g)$ is p-regular, then the graded Brauer character*

$$R(g,h;\tau) := q^{-1}\sum_{n\in\mathbb{Z}} \beta({}^g\mathcal{V}_n)(h)\, q^n$$

equals the McKay–Thompson series $T_{gh}(\tau)$. Moreover, for g belonging to any conjugacy class in $\mathbb{M}$ except 2B, 3B, 5B, 7B, or 13B, this is in fact an ordinary VOA (i.e. the 'odd' part vanishes), while in the remaining cases the graded Brauer characters of both the odd and even parts can separately be expressed using McKay–Thompson series.

By a vertex operator superalgebra, we mean there is a $\mathbb{Z}_2$-grading into even and odd subspaces, and for u, v both odd the commutator in (4.2a) is replaced by an anticommutator. In the proof, the superspaces arise as cohomology groups, which naturally form an alternating sum. The centralisers $C_\mathbb{M}(g)$ in the Theorem are quite nice: e.g. for g in classes 2A, 2B, 3A, 3B, 3C, 5A, 5B, 7A, 11A, respectively, these involve the sporadic groups $\mathbb{B}$, Co_1, Fi'_{24}, Suz, Th, HN, HJ, He, and M_{12}. The proof for $p = 2$ is not complete at the present time. The conjectures in [**105**] concerning modular analogues of the Griess algebra for several sporadics follow from Theorem 7.

Can these modular ${}^g\mathcal{V}$s be interpreted as a reduction mod p of (super)algebras in characteristic 0? Also, what about elements g of composite order?

CONJECTURE 8. [**13**] *Choose any $g \in \mathbb{M}$ and let n denote its order. Then there is a $\frac{1}{n}\mathbb{Z}$-graded superspace ${}^g\widehat{\mathcal{V}} = \oplus_{i\in\frac{1}{n}\mathbb{Z}}{}^g\widehat{\mathcal{V}}_i$ over the ring of cyclotomic integers $\mathbb{Z}[e^{2\pi i/n}]$. It is often (but probably not always) a vertex operator superalgebra — in particular ${}^1\widehat{\mathcal{V}}$ is an integral form of the Moonshine module $V^\natural$. Each ${}^g\widehat{\mathcal{V}}$ carries a representation of a central extension of $C_\mathbb{M}(g)$ by C_n. Define the graded trace*

$$B(g,h;\tau) = q^{-1}\sum_{i\in\frac{1}{n}\mathbb{Z}} \mathrm{ch}_{{}^g\widehat{\mathcal{V}}_i}(h)\, q^i\ .$$

If $g, h \in \mathbb{M}$ commute and have coprime orders, then $B(g, h; \tau) = T_{gh}(\tau)$. If all q-coefficients of T_g are nonnegative, then the 'odd' part of ${}^g\widehat{\mathcal{V}}$ vanishes, and ${}^g\widehat{\mathcal{V}}$ is the g-twisted module $V^\natural(g)$ of [**36**]. *If g has prime order p, then the reduction mod p of ${}^g\widehat{\mathcal{V}}$ is the modular vertex operator superalgebra ${}^g\mathcal{V}$ of Theorem 7.*

When we say ${}^1\widehat{\mathcal{V}}$ is an integral form for $V^\natural$, we mean that ${}^1\widehat{\mathcal{V}}$ has the same structure as a VOA, with everything defined over $\mathbb{Z}$, and tensoring it with $\mathbb{C}$ recovers $V^\natural$. This remarkable conjecture, which tries to explain Theorem 7, is completely open.

5.5. The geometry of Moonshine. Algebra is the mathematics of structure, and so of course it has a profound relationship with every area of mathematics. Therefore the trick for finding possible fingerprints of Moonshine in say geometry is to look there for modular functions. And that search quickly leads to the elliptic genus.

For details see e.g. [**55**], [**108**], [**112**]. All manifolds here are compact, oriented and differentiable. In Thom's cobordism ring Ω, elements are equivalence classes of cobordant manifolds, addition is connected sum, and multiplication is Cartesian product. The *universal elliptic genus* $\phi(M)$ is a ring homomorphism from $\mathbb{Q} \otimes \Omega$ to the ring of power series in q, which sends n-dimensional manifolds with spin connections to a weight $n/2$ modular form of $\Gamma_0(2)$ with integer coefficients. Several variations and generalisations have been introduced, e.g. the Witten genus assigns spin manifolds with vanishing first Pontryagin class a weight $n/2$ modular form of $\mathrm{SL}_2(\mathbb{Z})$ with integer coefficients.

Several deep relationships between elliptic genera and the general material reviewed elsewhere in this paper, have been uncovered. For instance, the important rigidity property of the Witten genus with respect to any compact Lie group action on the manifold, is a consequence of the modularity of the characters of affine algebras (our Theorem 4) [**81**]. The elliptic genus of a manifold M has been interpreted as the graded dimension of a vertex operator superalgebra constructed from M [**111**]. Seemingly related to this, [**18**] recovered the elliptic genus of a Calabi–Yau manifold X from the sheaf of vertex algebras in the chiral de Rham complex [**85**] attached to X. Unexpectedly, the elliptic genus of even-dimensional projective spaces P^{2n} has nonnegative coefficients and in fact equals the graded dimension of a certain vertex algebra [**86**]; this suggests interesting representation-theoretic questions in the spirit of Monstrous Moonshine. In physics, elliptic genera arise as partition functions of $N = 2$ superconformal field theories [**120**]. Mason's constructions [**88**] associated to Moonshine for the Mathieu group M_{24} have been interpreted as providing a geometric model ('elliptic system') for elliptic cohomology $\mathrm{Ell}^*(BM_{24})$ of the classifying space of M_{24} [**112**], [**39**]. The Witten genus (normalised by η^8) of the Milnor–Kervaire manifold M_0^8, an 8-dimensional manifold built from the E_8 diagram, equals $j^{\frac{1}{3}}$ [**55**] (recall (3.5)).

Hirzebruch's 'prize question' (p.86 of [**55**]) asks for the construction of a 24-dimensional manifold M with Witten genus J (after being normalised by η^{24}). We would like $\mathbb{M}$ to act on M by diffeomorphisms, and the twisted Witten genera to be the McKay–Thompson series T_g. It would also be nice to associate Norton's series $N(g, h)$ to this Moonshine manifold. Constructing such a manifold is perhaps the remaining Holy Grail of Monstrous Moonshine.

Hirzebruch's question was partially answered by Mahowald and Hopkins [**84**], who constructed a manifold with Witten genus J, but couldn't show it would support an effective action of $\mathbb{M}$. Related work is [**3**], who constructed several actions of $\mathbb{M}$ on e.g. 24-dimensional manifolds (but none of which could have genus J), and [**73**], who showed the graded dimensions of the subspaces $V^\natural_\pm$ of the Moonshine module are twisted $\widehat{A}$-genera of Milnor–Kervaire's manifold M_0^8 (the $\widehat{A}$-genus is the specialisation of elliptic genus to the cusp $\mathrm{i}\infty$).

There has been a second conjectured relationship between geometry and Monstrous Moonshine. *Mirror symmetry* says that most Calabi–Yau manifolds come in closely related pairs. Consider a 1-parameter family X_z of Calabi–Yau manifolds, with mirror X^* given by the resolution of an orbifold X/G for G finite and abelian. Then the Hodge numbers $h^{1,1}(X)$ and $h^{2,1}(X^*)$ will be equal, and more precisely the moduli space of (complexified) Kähler structures on X will be locally isometric to the moduli space of complex structures on X^*. The 'mirror map' $z(q)$, which can be defined using the Picard–Fuchs equation [**95**], gives a canonical map between those moduli spaces. For example, $x_1^4 + x_2^4 + x_3^4 + x_4^4 + z^{-1/4}x_1x_2x_3x_4 = 0$ is such a family of K3 surfaces, where $G = C_4 \times C_4$. Its mirror map is given by

$$z(q) = q - 104q^2 + 6444q^3 - 311744q^4 + 13018830q^5 - 493025760q^6 + \cdots \, . \tag{5.6}$$

Lian–Yau [**80**] noticed that the reciprocal $1/z(q)$ of the mirror map in (5.6) equals the McKay–Thompson series $T_g(\tau) + 104$ for g in class 2A of $\mathbb{M}$. After looking at several other examples with similar conclusions, they proposed their *Mirror-Moonshine Conjecture*: The reciprocal $1/z$ of the mirror map of a 1-parameter family of K3 surfaces with an orbifold mirror, will be a McKay–Thompson series (up to an additive constant).

A counterexample (and more examples) are given in §7 of [**118**]. In particular, although there are relations between mirror symmetry and modular functions (see e.g. [**51**] and [**54**]), there doesn't seem to be any special relation with the Monster. Doran [**40**] 'demystifies the Mirror-Moonshine phenomenon' by finding necessary and sufficient conditions for $1/z$ to be a modular function for a modular group commensurable with $\mathrm{SL}_2(\mathbb{Z})$.

6. The physics of Moonshine

The physical side (perturbative string theory, or equivalently conformal field theory) of Moonshine was noticed early on, and has profoundly influenced the development of Moonshine and VOAs. This is a very rich subject, which we can only superficially touch on. The book [**32**], with its extensive bibliography, provides an introduction but will be difficult reading for many mathematicians (as will this section!) The treatment in [**45**] is more accessible and shows how naturally VOAs arise from the physics. This effectiveness of physical interpretations isn't magic — it merely tells us that many of our finite-dimensional objects are seen much more clearly when studied through infinite-dimensional structures (often by being 'looped'). Of course Moonshine, which teaches us to study the finite group $\mathbb{M}$ via its infinite-dimensional module $V^\natural$, fits perfectly into this picture.

A conformal field theory (CFT) is a quantum field theory on 2-dimensional space-time, whose symmetries include the conformal transformations. In string theory the basic objects are finite curves ('strings') rather than points ('particles'), and the CFT lives on the surface traced by the strings as they evolve (colliding and separating) through time. Each CFT is associated with a pair $\mathcal{V}_L, \mathcal{V}_R$ of mutually commuting VOAs, called its *chiral algebras* [**6**]. For example, strings living on a compact Lie group manifold (the so-called Wess–Zumino–Witten model) will have chiral algebras given by affine algebra VOAs. The space $\mathcal{H}$ of states for the CFT carries a representation of $\mathcal{V}_L \otimes \overline{\mathcal{V}}_R$, and many authors have (somewhat optimisticly) concluded that the study of CFTs reduces to that of VOA representation theory. Rational VOAs correspond to the important class of *rational* CFTs, where $\mathcal{H}$ decomposes into a finite sum $\oplus M_L \otimes M_R$ of irreducible modules. The Virasoro algebra (4.3) arises naturally in CFT through infinitesimal conformal transformations. The vertex operator $Y(\phi, z)$, for the space-time parameter $z = e^{t+\mathrm{i}x}$, is the quantum field which creates from the vacuum $|0\rangle \in \mathcal{H}$ the state $|\phi\rangle \in \mathcal{H}$ at time $t = -\infty$: $|\phi\rangle = \lim_{z\to 0} Y(\phi, z)\,|0\rangle$. In particular, Borcherds' definition [**9**] of VOAs can be interpreted as an axiomatisation of the notion of chiral algebra in CFT, and for this reason alone is important.

In CFT, the Hauptmodul property of Moonshine is hard to interpret, and a less direct formulation like that in [**116**] is needed. However, both the statement and proof of Theorem 5 are natural from the CFT framework (see [**45**]) — e.g. the modularity of the series T_g and $N(g, h)$ are automatic in CFT. This modularity arises in CFT through the equivalence of the Hamiltonian formulation, which describes concretely the graded spaces we take traces on (and hence the coefficients of our q-expansions), and the Feynman path formalism, which interprets these graded traces as sections over moduli spaces (and hence makes modularity manifest). Beautiful reviews are sketched in [**119**], [**120**].

Because $V^\natural$ is so mathematically special, it may be expected that it corresponds to interesting physics. Certainly it has been the subject of some speculation. There will be a $c = 24$ rational CFT whose chiral algebra $\mathcal{V}_L$ and state space $\mathcal{H}$ are both $V^\natural$, while $\mathcal{V}_R$ is trivial (this is possible because $V^\natural$ is holomorphic). This CFT is nicely described in [**34**]; see also [**35**]. The Monster is the symmetry of that CFT, but the Bimonster $\mathbb{M} \wr C_2$ will be the symmetry of a rational CFT with $\mathcal{H} = V^\natural \otimes \overline{V^\natural}$. The paper [**27**] finds a family of D-branes for the latter theory which are in one-to-one correspondence with the elements of $\mathbb{M}$, and their 'overlaps' $\langle\!\langle g \| q^{\frac{1}{2}(L_0+\bar{L}_0-\frac{c}{24})} \| h\rangle\!\rangle$ equal the McKay–Thompson series $T_{g^{-1}h}$. However, we still lack any explanation as to why a CFT involving $V^\natural$ should yield interesting *physics*.

Almost every facet of Moonshine finds a natural formulation in CFT, where it often was discovered first. For example, the 'No-Ghost' Theorem of Brower–Goddard–Thorn was used to great effect in [**11**] to understand the structure of the Monster Lie algebra $\mathfrak{m}$. On a finite-dimensional manifold M, the index of the Dirac operator D in the heat kernel interpretation is a path integral in supersymmetric quantum mechanics, i.e an integral over the free loop space $\mathcal{L}M = \{\gamma : S^1 \to M\}$; the string theory version of this is that the index of the Dirac operator on $\mathcal{L}M$ should be an integral over $\mathcal{L}(\mathcal{L}M)$, i.e. over smooth maps of tori into M, and this is just the elliptic genus, and explains why it should be modular. The orbifold construction of [**36**] comes straight from CFT (although [**43**]'s construction of $V^\natural$ predates CFT orbifolds by a year and in fact influenced their development in physics). That said, the translation process from physics to mathematics of course is never easy — Borcherds' definition [**9**] is a prime example!

But from this standpoint, what is most exciting is what hasn't yet been fully exploited.

String theory tells us that CFT can live on any surface Σ. The VOAs, including the geometric VOAs of [**59**], capture CFT in genus 0. The graded dimensions and traces considered above concern CFT quantities ('conformal blocks') at genus 1: $\tau \mapsto e^{2\pi \mathrm{i}\tau}$ maps $\mathbb{H}$ onto a cylinder, and the trace identifies the two ends. But there are analogues of all this at higher genus [**123**] (though the formulas can rapidly become awkward). For example, the graded dimension of e.g. the $V^\natural$ CFT in genus 2 is computed in [**117**], and involves e.g. Siegel theta functions. The orbifold theory in §5.1 is genus 1: each 'sector' (g, h) corresponds to a homomorphism from the fundamental group $\mathbb{Z}^2$ of the torus into the orbifold group G (e.g $G = \mathbb{M}$) — g and h are the targets of the two generators of $\mathbb{Z}^2$ and hence must commute. More generally, the sectors will correspond to each homomorphism $\varphi : \pi_1(\Sigma) \to G$, and to each we will get a higher genus trace $\mathcal{Z}(\varphi)$, which will be a function on the Teichmüller space T_g (generalising the upper half-plane $\mathbb{H}$ for genus 1). The action of $\mathrm{SL}_2(\mathbb{Z})$ on the $N(g, h)$ generalises to the action of the mapping class group on $\pi_1(\Sigma)$ and T_g. See e.g. [**4**] for some thoughts in this direction.

7. Conclusion

There are different basic aspects to Monstrous Moonshine: (i) why modularity enters at all; (ii) why in particular we have genus 0; and (iii) what does it have to do with the Monster. We understand (i) best. There will be a Moonshine-like relation between any (subgroup of the) automorphism group of any rational VOA, and the characters χ_M, and the same can be expected to hold of the orbifold characters $\mathcal{Z}$ in §5.1.

To prove the genus 0 property of the T_g, we needed recursions obtained one way or another from the Monster Lie algebra $\mathfrak{m}$, and from these we apply Theorem 6. These recursions are very special, but so presumably is the genus 0 property. The suggestion of [**20**] though is that we may be able to considerably simplify this part of the argument.

Every group known to have rich Moonshine properties is contained in the Monster. Our understanding of this seemingly central role of $\mathbb{M}$ is the poorest of those three aspects.

It should be clear from this review, of the central role VOAs play in our current understanding of Moonshine. The excellent review [**39**] makes this point even more forcefully. It can be (and has been) questioned though whether the full and difficult machinery of VOAs is really needed to understand this, i.e. whether we really have isolated the key conjunction of properties needed for Moonshine to arise. CFT has been an invaluable guide thus far, but perhaps we are a little too steeped in its lore.

Moonshine (in its more general sense) is a relation between algebra and number theory, and its impact on algebra has been dramatic (e.g. VOAs, $V^\natural$, Borcherds–Kac–Moody algebras). Its impact on number theory has been far less so. This may merely be a temporary accident due to the backgrounds of most researchers (including the mathematical physicists) working to date in the area. But the most exciting prospects for the future of Moonshine (in this writer's opinion) are in the direction of number theory. Hints of this future can be found in e.g. [**121**], [**41**], [**14**], [**33**], [**52**], [**94**].

Acknowledgements. This paper was written at IHES and at U of Wales Swansea, and I thank both for their hospitality. Much of what I've learned of Moonshine came from conversations over the years with Chris Cummins and John McKay, and I warmly thank both. I appreciate the many comments and suggestions provided by the readers of the first draft; in this vein I would particularly like to mention James Lepowsky and Fyodor Malikov. My research is supported in part by NSERC.

Abstract

Eguchi, Ooguri and Tachikawa have observed that the elliptic genus of type II string theory on K3 surfaces appears to possess a Moonshine for the largest Mathieu group. Subsequent work by several people established a candidate for the elliptic genus twisted by each element of M_{24}. In this paper we prove that the resulting sequence of class functions are true characters of M_{24}, proving the Eguchi-Ooguri-Tachikawa conjecture. The integrality of multiplicities is proved using a small generalisation of Sturm's Theorem, while positivity involves a modification of a method of Hooley. We also prove the evenness property of the multiplicities, as conjectured by several authors. We also identify the role group cohomology plays in both K3-Mathieu Moonshine and Monstrous Moonshine; in particular this gives a cohomological interpretation for the non-Fricke elements in Norton's Generalised Monstrous Moonshine conjecture. We investigate the proposal of Gaberdiel-Hohenegger-Volpato that K3-Mathieu Moonshine lifts to the Conway group Co_1.

1 Introduction

The elliptic genus (a.k.a. partition function) of a nonlinear sigma model with K3 target space is a very special function. On general grounds, it is a weak Jacobi form of index one and weight zero for $\mathbb{Z}^2 \rtimes \mathrm{SL}_2(\mathbb{Z})$, and is therefore equal to the unique (up to scaling) such function, $\phi_{0,1}(z,\tau)$. This implies it is topological in the sense that it is independent of where you are on the 20-(complex) dimensional K3 moduli space, or indeed of where you are on the 40-dimensional moduli space of K3 sigma models.

The world-sheet description of these string theories is as an $N = 4$ superconformal field theory, and thus the whole state space can be organised as an $N = 4$ superconformal representation. In particular, the elliptic genus can be decomposed into sums of elliptic genera of $N = 4$ superconformal representations. Eguchi, Ooguri and Tachikawa [24] observed that the multiplicities with which these $N = 4$ elliptic genera contribute to the elliptic genus are dimensions of M_{24}-group representations.

According to Conway, the sporadic simple group M_{24} is the most remarkable of all finite groups (p.300, [9]), with a great wealth of structure and applications. For instance it is the automorphism group of the Golay code, a stabilizer in the Leech lattice, and all symplectic symmetries of K3 surfaces can be embedded in it (in fact in a subgroup M_{23}) [42, 39]. Its order (size) is 244 823 040, and class number (i.e. number of conjugacy classes) is 26. The character table is given in Table 1; we retain the order of irreps(= irreducible representations) in [8], relate with a bar the complex conjugate irrep (when nonisomorphic), and write $\rho_0 = 1$ for the trivial representation. We write there $\alpha_t^s = (s + t\mathrm{i}\sqrt{7})/2$, $\beta_t^s = (s + t\mathrm{i}\sqrt{15})/2$, and $\gamma_t^s = (s + t\mathrm{i}\sqrt{23})/2$, for all choices of signs $s, t \in \{\pm 1\}$.

K3-Mathieu Moonshine was pushed further — indeed, made well-defined — by the work of Cheng [5], Gaberdiel, Hohenegger & Volpato [28, 29] and Eguchi & Hikami [20] who calculated the analogue $\phi_g(\tau, z)$ of the McKay-Thompson series here. The resulting functions are weak Jacobi forms for $\mathbb{Z}^2 \rtimes \Gamma_0(|g|)$ up to certain phases ($|g|$ denotes the order of $g \in M_{24}$). At the conclusion of this paper (see also [31]) we identify the cohomological source of these phases. The K3-Mathieu Moonshine fits beautifully into this general cohomological framework of conformal field theory (CFT) [31].

Once we know the weak Jacobi forms ϕ_g, we obtain modular forms f_g from (2.10) below and can read off the class functions H_n from (2.11) and (2.13) (a class function is a function constant on conjugacy classes). These H_n can also be obtained explicitly from (4.4) below. In any case, our most important result is the proof that these class functions H_n are all true representations of M_{24}. This can be regarded as a proof of the weak form of the K3-Mathieu moonshine conjecture.

Theorem A. *Each H_n ($n \geq 1$) is a true character of M_{24} (i.e. a sum of irreducible characters of M_{24}).*

The *strong* conjecture says that these ϕ_g are the twisted elliptic genera of an $N = 4$ vertex operator superalgebra — we have nothing to say about this. One would have liked to prove Theorem A by explicitly constructing these M_{24}-representations H_n. This remains an important challenge. Instead, we prove Theorem A in two steps.

The first step in showing this is to prove that the H_n are *virtual characters*, i.e. linear combinations over the integers of irreducible characters. It can be easily shown that the coefficients $H_n(g)$ will be *integer-valued* class functions, but this only implies the class function is a linear combination over $\mathbb{Q}$ of irreducibles, with denominators dividing the order $|G|$ of the group (244 million, in our case!). We prove the H_n are virtual by verifying that for each n the quantities $H_n(g)$ satisfy certain congruences; we can verify this simultaneously for all n by studying mod p^α reductions of associated modular forms. (Our result Lemma 3 on mod n reductions of modular forms is a refinement of older results in the literature.)

The other and more difficult step in proving Theorem A, is to show that each $H_n(g)$ is a *nonnegative* (real) linear combination of irreducible characters. It is easy to reduce this to showing that for any $g \neq 1$, $|H_n(g)|$ is small compared to $H_n(1)$ for all $n > N$ for some N (the coefficients for $n \leq N$ are then checked explicitly). Thanks to [6] we know

$$H_n(g) = \mathcal{O}\left(\frac{e^{\pi\sqrt{8n-1}/2|g|}}{\sqrt{8n-1}}\right) \tag{1.1}$$

where $|g|$ denotes the order of g, so for all $n > N$, where N is sufficiently large, $H_n(1)$

will dwarf $H_n(g)$ for $g \neq 1$, but we need to make this *effective* by finding that N, and this is the hard part of this positivity argument. It is tempting to guess we could follow Rademacher's calculation of effective bounds for the partition numbers, which looks like it should be similar, but Rademacher's series was absolutely convergent whereas those in [6] aren't, so the argument is much more delicate. But the analogy with partition numbers is still useful: *generalised* Kloosterman sums arise here, and the corresponding zeta functions are what we need to bound; but Whiteman [51] showed long ago that the classical Kloosterman sum has an elegant expression as a sparse sum, and Hooley [37] explained how to use the theory of binary quadratic forms to bound series associated to similar sums, so we follow their lead. This involves though finding significant generalisations of Whiteman's and Hooley's results. As an aside, our inequalities yield an independent proof of the convergence of the Rademacher sum expressions in [6].

Integrality of these multiplicities is crucial. In contrast, the significance of positivity is not as clear to this author — after all, elliptic genus is a *signed* trace. What happens here should be contrasted with the $N = 4$ $c = 6$ toroidal theories, where the elliptic genus vanishes. Positivity could be a consequence of the minimality of this string theory (see e.g. the discussions in [44],[52]) — we return to this important question in the conclusion. In any case, it is intriguing to note that the elliptic genera of the M_{24}-twisted modules (these have been recently obtained in [31]) also appear to be true representations (of the appropriate central extension of centralisers in M_{24}).

Our methods of proving weak Moonshine are quite robust. In particular, they can surely be applied to the twisted twining Mathieu Moonshine elliptic genera of [31], the 'Umbral Moonshine' of [7] and the $\mathrm{PSL}_2(\mathbb{Z}_{11})$ $N = 2$ Moonshine of [21] (as well of course to Monstrous Moonshine itself).

It is a consequence of our proof that the multiplicities $\mathrm{mult}_{\rho_i}(H_n)$ tend to infinity with n, for each i, and all $\mathrm{mult}_{\rho_i}(H_n)$ are strictly positive for $n \geq 25$. See Theorem 4 below.

It is common in the Mathieu Moonshine literature to emphasise the presence of *mock* modular forms. Indeed, the sums $q^{-1/8}\sum_{n=0}^{\infty} H_n(g)q^n$ are mock modular for each g, not (usually) modular. We had no use however of mock modularity in this paper; however the true modularity of the derived functions we call f_g plays a crucial role.

In Section 3 we also obtain an evenness result conjectured by several authors:

Theorem B. *Each head character H_n is a sum of*

$$\{2, 2\rho_1, \rho_2 + \overline{\rho_2}, \rho_3 + \overline{\rho_3}, 2\rho_4, 2\rho_5, 2\rho_6, \rho_7 + \overline{\rho_7}, \rho_8 + \overline{\rho_8}, 2\rho_9, \\ \rho_{10} + \overline{\rho_{10}}, 2\rho_{11}, 2\rho_{12}, 2\rho_{13}, 2\rho_{14}, 2\rho_{15}, 2\rho_{16}, 2\rho_{17}, 2\rho_{18}, 2\rho_{19}, 2\rho_{20}\}$$

Theorems A and B are both used in [12] to prove a conjecture in Umbral Moonshine [7]. Indeed, their Theorem 1.2 is far stronger than Conjecture 5.11 in [7] (specialised to M_{24}), and a little weaker than Conjecture 5.12 in [7]. Incidentally, it is curious that imaginary quadratic fields play a role in Umbral Moonshine (see Section 5.4 of [7]) while the equivalent theory of positive-definite quadratic forms plays a crucial role in our Section 4 proof. Perhaps this can supply a deeper explanation for Conjecture 5.12 than would arise from arguments as in [12].

Theorems A and B also imply that the elliptic genus of Enriques surfaces can be decomposed into true characters of M_{12} [22] (their elliptic genus is half that of K3 surfaces, so positivity comes from Theorem A and integrality from Theorem B). The VOA or string theoretic interpretation of this observation seems quite obscure.

[30] made the intriguing proposal that in fact the much larger Conway groups Co_0 or Co_1 may act. We prove (Gerald Höhn notified us that he also has a proof):

Theorem C. *All H_n, as well as H_{00}, are restrictions of virtual representations of Co_0.*

This was a nontrivial obstruction to their suggestion. However, as we explain below, the virtual Co_0-representations are much larger than the underlying M_{24}-representations (i.e. in the restriction a large representation with negative multiplicity cancels a large representation with positive multiplicity, leaving the small remainder H_n). Indeed, it now seems few people expect Mathieu Moonshine to extend to Co_0. Of course Theorem C implies that the same conclusion necessarily holds when Co_0 is replaced there with any subgroup between M_{24} and Co_0. In the conclusion, we mention the other group that should be considered a candidate for enhanced symmetry in Mathieu Moonshine.

In our paper, and indeed in much work on the subject, no relation involving K3 is used or obtained. It seems possible to us that the connection with K3 may be illusory. This would be very disappointing. We return to this a little more in the concluding section.

Because a fairly wide range of readers are potentially interested in parts of this paper, and may wish to extend it to other Moonshines, we have endeavoured to keep it as accessible and as detailed as possible.

2 K3-Mathieu Moonshine: Review

Throughout this paper, write $e(x) = \exp(2\pi \mathrm{i} x)$. For readability we will often collapse $a \equiv b \pmod{m}$ to $a \equiv_m b$. We will write $|g|$ for the order $|\langle g \rangle|$ of the element g of a group. An excellent review of superconformal field theories and their moduli spaces and elliptic genera, including $N = 4$ $c = 6$, is included in [52].

The elliptic genus of a sigma model with Calabi-Yau target is defined to be [54]

$$\phi(\tau, z) = \mathrm{Tr}_{H_{RR}}(q^{L_0 - c/24} e(zJ_0)(-1)^F \overline{q}^{\overline{L}_0 - c/24}), \tag{2.1}$$

where $q = e(\tau)$. Here, L_0 resp. $\overline{L}_0$ are the holomorphic resp. antiholomorphic Virasoro generators defining the grading, J_0 is an operator of $N = 2$ supersymmetry defining the charge, and F is the Fermionic number operator. The central charge c equals $3d$, where d is the (complex) dimension of the Calabi-Yau target. $\phi(\tau, z)$ will be independent of $\overline{q}$, by virtue of the supersymmetry in the Ramond sector, and depends only on the topological type (rather than the complex structure) of the target. It is a *weak Jacobi form* of index $m = d/2$ and weight $k = 0$ for $\mathbb{Z}^2 \rtimes \mathrm{SL}_2(\mathbb{Z})$. This means that ϕ is a holomorphic function of $z \in \mathbb{C}$ and $\tau \in \mathbb{H}$, the upper half-plane, which is modular with respect to τ and quasi-periodic with respect to z: for all $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ and $l, l' \in \mathbb{Z}$,

$$\phi\left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\right) = (c\tau + d)^k e(mcz^2/(c\tau + d))\phi(\tau, z) \ , \tag{2.2}$$

$$\phi(\tau, z + l\tau + l') = e(-\mathrm{i}m\,(l^2\tau + 2lz))\phi(\tau, z) \ , \tag{2.3}$$

and in addition has Fourier expansion

$$\phi(\tau, z) = \sum_{n \geq 0, l \in \mathbb{Z}} c(n, l) q^n y^l \ , \tag{2.4}$$

for $y = e(z)$. Consistency of these conditions requires $c(n, l) = (-1)^k c(n, -l)$. The prefix 'weak' denotes that the sum over n is allowed to start at 0, i.e. ϕ is merely holomorphic at the cusp $\tau = \mathrm{i}\infty$; for historical reasons to be a true *Jacobi form* requires a sum over $l^2 \leq 4mn$.

The theory of Jacobi forms is developed in [25]. The definition extends trivially to weak Jacobi forms for other $\mathbb{Z}^2 \rtimes \Gamma$, where Γ is any subgroup of $\mathrm{SL}_2(\mathbb{Z})$ of finite index. Note that because we have insisted here on the full group $\mathbb{Z}^2$ of translations, Γ must be a subgroup of $\mathrm{SL}_2(\mathbb{Z})$ because it must act on that group of translations. This is significant because it means we will lose the genus-0 property which played so important a role in Monstrous Moonshine — recall that many of the Monstrous Moonshine Fuchsian groups aren't subgroups of $\mathrm{SL}_2(\mathbb{Z})$.

Nevertheless, the genus-0 property is what made Monstrous Moonshine special (and rather mysterious), so we should seek an analogue for it in Mathieu Moonshine. [6] have an intriguing proposal: that the mock modular form $q^{-1/8} \sum_n H_n(g) q^n$ equals a certain regularised Rademacher sum. The relation of such a property (in weight-0) to the genus-0 property was established in [17].

The algebra of weak Jacobi forms for $\mathbb{Z}^2 \rtimes \Gamma$ of even weight and integral index, is the polynomial algebra $\mathfrak{m}_\Gamma[\phi_{0,1}, \phi_{-2,1}]$, where $\mathfrak{m}_\Gamma$ is the ring of holomorphic modular forms for Γ, and

$$\phi_{0,1}(\tau, z) = 4\left(\frac{\theta_2(\tau, z)^2}{\theta_2(\tau, 0)^2} + \frac{\theta_3(\tau, z)^2}{\theta_3(\tau, 0)^2} + \frac{\theta_4(\tau, z)^2}{\theta_4(\tau, 0)^2}\right) \ , \ \phi_{-2,1}(\tau, z) = -\frac{\theta_1(\tau, z)^2}{\eta(\tau)^6} \ , \tag{2.5}$$

for the classical Jacobi theta series θ_i and Dedekind eta function η. (For $\Gamma = \mathrm{SL}_2(\mathbb{Z})$ this is Proposition 9.3 in [25], but the proof for arbitrary finite-index Γ is the same.) In particular, every weight-0 index-1 weak Jacobi form $F(\tau, z)$ for $\mathbb{Z}^2 \rtimes \Gamma$ can be expressed as $F = h\phi_{0,1} + f\phi_{-2,1}$, where $h \in \mathbb{C}$ and f is a holomorphic weight-2 modular form for Γ. For nonlinear σ-models on K3, this implies the elliptic genus $\phi(\tau, z)$ must be proportional to $\phi_{0,1}$ and therefore will be constant throughout the 40-dimensional moduli space of K3 sigma models, something we already knew.

The worldsheet description is of an $N = 2$ vertex operator super algebra (VOSA). The holonomy of K3 surfaces extends the $N = 2$ to $N = 4$. Therefore, the space H_{RR} in fact carries a representation of the $N = 4$ superconformal algebra at $c = 6$, so

$$\phi_{K3}(\tau, z) = A_{00} ch^s_{1/4,0}(\tau, z) + \sum_{n=0}^{\infty} A_n ch^l_{n+1/4,1/2}(\tau, z)\,, \tag{2.6}$$

where $ch^*_{h,j}(\tau, z)$ is the elliptic genus of the appropriate level 1 $N = 4$ representation ($s =$short=massless=BPS, $l =$long=massive=non-BPS) and $ch^l_{1/4,1/2}$ is to be interpreted as $ch^s_{0,0} + 2ch^s_{1/4,1/2}$. Eguchi, Ooguri & Tachikawa [24] remarked that these coefficients A_n, previously calculated in [23], appear to be dimensions of M_{24}-representations (except for $n = 0$). More precisely, $A_{00} = 20$ is the dimension of the virtual representation $H_{00} = \rho_1 - 3\rho_0 = \rho_1 - 3$, and A_n is the dimension of H_n, where H_0 is the virtual representation -2, and the next few are

$$\begin{aligned}
&H_1 = \rho_2 + \overline{\rho_2}\,, \quad H_2 = \rho_3 + \overline{\rho_3}\,, \quad H_3 = \rho_7 + \overline{\rho_7}\,, \quad H_4 = 2\rho_{14}\,, \quad H_5 = 2\rho_{19}\,,\\
&H_6 = 2\rho_{20} + 2\rho_{16}\,, \quad H_7 = 2\rho_{20} + 2\rho_{19} + 2\rho_{18} + 2\rho_{17} + 2\rho_{13} + 2\rho_{12}\,,\\
&H_8 = 6\rho_{20} + 2\rho_{19} + 2\rho_{18} + 4\rho_{17} + 2\rho_{16} + 2\rho_{15} + 2\rho_{14} + 2\rho_{11} + \rho_{10} + \overline{\rho_{10}} + \rho_8 + \overline{\rho_8}\,,\\
&H_9 = 10\rho_{20} + 8\rho_{19} + 8\rho_{18} + 4\rho_{17} + 4\rho_{16} + 4\rho_{15} + 2\rho_{14} + 2\rho_{13} + 2\rho_{12} + 2\rho_{10} + 2\overline{\rho_{10}}\\
&\qquad\quad +2\rho_9 + 2\rho_7 + 2\overline{\rho_7} + 2\rho_6\,.
\end{aligned}$$

(Incidentally, [21] note that expanding the elliptic genus into $N = 2$ characters (rather than $N = 4$) seems to carry a representation of $\mathrm{PSL}_2(\mathbb{Z}_{11})$, a simple group of order 660.)

This observation of [24] is very reminiscent of the Monstrous Moonshine observation of McKay who noted that the expansion coefficients of the Hauptmodul J-function seem to be dimensions of Monster group $\mathbb{M}$ representations V_n (see e.g. [32] for a review and references). Thompson suggested considering what are now called the *McKay-Thompson series*, defined formally for all $g \in \mathbb{M}$ by

$$T_g(\tau) = \sum_{n=-1}^{\infty} \mathrm{ch}_{Vn}(g)\, q^n\,, \tag{2.7}$$

where $q = e^{2\pi \mathrm{i}\tau}$. Note that these T_g are constant on each of the 194 conjugacy classes of $\mathbb{M}$ — they are called *class functions.* After staring at their first few coefficients, Conway & Norton [9] conjectured that these T_g are modular functions (in fact Hauptmoduls=normalised generators of the field of modular functions) for some genus-0 Fuchsian group Γ_g commensurable with (but not in general a subgroup of) $\mathrm{SL}_2(\mathbb{Z})$. To make this conjecture more precise, we should turn the logic around and associate to each conjugacy class K_g in $\mathbb{M}$ a uniquely specified modular function T_g. From their Fourier coefficients we obtain a sequence χ_n of *class functions*, i.e. linear combinations over $\mathbb{C}$ of irreducible characters of $\mathbb{M}$. Because the coefficients of the T_g are rational (in fact integral), it is immediate that this linear combination can be taken over $\mathbb{Q}$, but it is very hard to show they can be taken over $\mathbb{Z}$ (i.e. that these class functions χ_n are virtual characters) and even harder to show that they are combinations over $\mathbb{Z}_{\geq 0}$ (i.e. that the χ_n are actually characters of $\mathbb{M}$-representations M_n). Atkin, Fong & Smith (see [48]) tried to prove with the aid of a computer that these χ_n are indeed true characters, and managed to reduce the proof to a fairly plausible statement they called Conjecture 2.3 (it is often claimed in the literature — see e.g. [32] — that [48] proves the χ_n are true characters, but this is false). That Conway-Norton conjecture was finally proved in [2], independently of [48]; thanks to this work, we now know much more: there is a vertex operator algebra (VOA) $\mathcal{V}^\natural$ (constructed in [27]) with automorphism group $\mathbb{M}$, whose *twining characters* $\mathrm{Tr}_{\mathcal{V}^\natural} g q^{L_0 - 1}$ equal the McKay–Thompson series T_g (the '-1' in the exponent is the usual shift by $c/24$). In other words, the $\mathbb{M}$-modules V_n are the eigenspaces of $V^\natural$ with respect to the Virasoro operator L_0. (The adjective 'twining' is short for 'intertwining', and is used as an alternative to the over-used word 'twisted'.)

Thus we are led to test further this Mathieu Moonshine observation of [24], by introducing for each $g \in M_{24}$

$$\phi_g(\tau, z) = \mathrm{ch}_{H00}(g)\, \mathrm{ch}_{1/4,0}(\tau, z) + \sum_{n=0}^{\infty} \mathrm{ch}_{Hn}(g)\, \mathrm{ch}_{n+1/4,1/2}(\tau, z)\,. \tag{2.8}$$

These should be the *twining elliptic genera*

$$\phi_g(\tau, z) = \mathrm{Tr}_{H_{RR}} g q^{L_0 - c/24} e(zJ_0)(-1)^F \overline{q}^{\overline{L}_0 - c/24}\,, \tag{2.9}$$

although that expression is purely formal as none of these K3 sigma models will have a symmetry consisting of all of M_{24}. In fact [42], the group of symplectic automorphisms of any K3 surface will typically be trivial, will never exceed order 960, and will only contain elements of order ≤ 8. And no automorphism, symplectic or otherwise, of a K3 surface can have order 23. But ignore these subtleties for now. Twining elliptic genera should have good modular properties — we would expect them to be weight-0 index-1 Jacobi forms for $\mathbb{Z}^2 \rtimes \Gamma_0(|g|)$ (recall we write $|g|$ for the order of g) though possibly with multiplier. This is enough to guess with effort these ϕ_g from the first few coefficients (just as was done in Monstrous Moonshine by Conway & Norton).

Conjectured expressions for ϕ_g, for all $g \in M_{24}$ (constant on conjugacy classes of course) were obtained in [5, 28, 29, 20]. We have

$$\phi_g(\tau, z) = \frac{w_g}{12} \phi_{0,1}(\tau, z) + f_g(\tau)\, \phi_{-2,1}(\tau, z)\,, \tag{2.10}$$

where $w_g \in \mathbb{Z}$ is the *Witten index* given in Table 2, and $f_g(\tau)$ is some holomorphic weight-2 modular form (with trivial multiplier) for $\Gamma_0(|g|h_g)$ for h_g in Table 2. w_g equals the character value of $\rho_1 + 1$ at g; note that it vanishes iff K_g doesn't intersect M_{23} — this isn't deep: $\rho_1 + 1$ is the permutation representation, so K_g intersects M_{23} iff $\rho_1 + 1$ has a fixed point, iff its character value (which equals the number of fixed-points) is nonzero. h_g is the length of the shortest cycle in the cycle shape of g. Note that in all cases, $h_g | \gcd(N, 12)$ (where N is the order of the element), and

$h_g = 1$ iff the conjugacy class K_g intersects M_{23}. We include for later use the order of the centraliser $C_{M24}(g)$ of g in M_{24}, and the index of $\Gamma_0(|g|)$ in $\mathrm{SL}_2(\mathbb{Z})$ (the index of $\Gamma_0(\prod_i p_i^{a_i})$, where p_i are distinct primes, is $\prod_i (p_i+1)p_i^{a_i-1}$), as well as the bound $a \times 10^b$ obtained by Theorem 3 below. In Table 2 and elsewhere, we write $7AB$ for $7A \cup 7B$ etc; we collect together conjugacy classes like this when the corresponding Jacobi forms ϕ_g coincide.

Table 2. Data for M_{24} conjugacy classes

K_g	1A	2A	2B	3A	3B	4A	4B	4C	5A	6A	6B	7AB	8A	10A	11A	12A	12B	14AB	15AB	21AB	23AB

Extracting f_g from (2.10), we obtain

$$\begin{aligned} f_g(\tau) &= w_g \frac{\theta_3^4+\theta_4^4}{12} - w_g\,\theta_3\theta_4\left(\frac{1}{4} + \sum_{n=1}^{\infty}\frac{q^{n(n+1)/2}}{1+q^n}\right) - \eta^3 q^{-1/8}\sum_{n=0}^{\infty} H_n(g) q^n \\ &= -\eta^3 q^{-1/8} \sum_{n=0}^{\infty}\Big(H_n(g) - \frac{w_g}{24}H_n(1)\Big)\, q^n\,. \end{aligned} \tag{2.11}$$

These modular forms $f_g(\tau)$ are given explicitly (i.e. independently of knowing the $H_n(g)$) for all $g \in M_{24}$ in [30, 20] (see also Table 2 of [6]). Indeed, recall the Eisenstein series $E_2(\tau) = 1 - 24q - 72q^2 - \cdots$, a quasi-modular form for $\mathrm{SL}_2(\mathbb{Z})$. Then for each integer $n > 1$,

$$E_2^{(n)}(\tau) := \frac{1}{n-1}(E_2(n\tau) - E_2(\tau)) = 1 + \frac{24}{n-1}\sum_{k=1}^{\infty}\sigma_1(k)\left(q^k - q^{nk}\right) \tag{2.12}$$

is a holomorphic modular form of weight 2 for $\Gamma_0(n)$ with trivial multiplier ($\sigma_1(k) = \sum_{d|k} d$). Writing $\eta(n) := \eta(n\tau)$ and $\eta = \eta(\tau)$, we have: $f_{1A} = 0$,

$$\begin{aligned} f_{2A} &= \frac{4}{3}E_2^{(2)} = \frac{4}{3} + 32q + 32q^2 + 128q^3 + 32q^4 + 192q^5 + 128q^6 + 256q^7 + 32q^8 + 416q^9 \cdots, \\ f_{2B} &= 2\frac{\eta^8}{\eta(2)^4} = 2 - 16q + 48q^2 - 64q^3 + 48q^4 - 96q^5 + 192q^6 - 128q^7 + 48q^8 - 208q^9 + \cdots, \\ f_{3A} &= \frac{3}{2}E_2^{(3)} = \frac{3}{2} + 18q + 54q^2 + 18q^3 + 126q^4 + 108q^5 + 54q^6 + 144q^7 + 270q^8 + 18q^9 + \cdots, \\ f_{3B} &= 2\frac{\eta^6}{\eta(3)^2} = 2 - 12q + 18q^2 + 24q^3 - 84q^4 + 36q^5 + 72q^6 - 96q^7 + 90q^8 + 24q^9 + \cdots, \\ f_{4A} &= 2\frac{\eta(2)^8}{\eta(4)^4} = 2 - 16q^2 + 48q^4 - 64q^6 + 48q^8 + 0q^9 + \cdots, \\ f_{4B} &= 2E_2^{(4)} - \frac{1}{3}E_2^{(2)} = \frac{5}{3} + 8q + 40q^2 + 32q^3 + 40q^4 + 48q^5 + 160q^6 + 64q^7 + 40q^8 + 104q^9 + \cdots, \\ f_{4C} &= 2\frac{\eta^4\eta(2)^2}{\eta(4)^2} = 2 - 8q + 32q^3 - 16q^4 - 48q^5 + 64q^7 + 48q^8 - 104q^9 + \cdots, \end{aligned}$$

$$\begin{aligned}
f_{5A} &= \frac{5}{3}E_2^{(5)} = \frac{5}{3} + 10q + 30q^2 + 40q^3 + 70q^4 + 10q^5 + 120q^6 + 80q^7 + 150q^8 + 130q^9 + \cdots\,, \\
f_{6A} &= \frac{5}{2}E_2^{(6)} - \frac{1}{2}E_2^{(3)} - \frac{1}{6}E_2^{(2)} = \frac{11}{6} + 2q + 14q^2 + 26q^3 + 38q^4 + 12q^5 + 38q^6 + 16q^7 + 86q^8 + 98q^9 + \cdots\,, \\
f_{6B} &= 2\frac{\eta^2\eta(2)^2\eta(3)^2}{\eta(6)^2} = 2 - 4q - 6q^2 + 8q^3 + 12q^4 + 12q^5 - 24q^6 - 32q^7 - 6q^8 + 8q^9 + \cdots\,, \\
f_{7AB} &= \frac{7}{4}E_2^{(7)} = \frac{7}{4} + 7q + 21q^2 + 28q^3 + 49q^4 + 42q^5 + 84q^6 + 7q^7 + 105q^8 + 91q^9 + \cdots\,, \\
f_{8A} &= \frac{7}{3}E_2^{(8)} - \frac{1}{2}E_2^{(4)} = \frac{11}{6} + 4q + 12q^2 + 16q^3 + 44q^4 + 24q^5 + 48q^6 + 32q^7 + 44q^8 + 52q^9 + \cdots\,, \\
f_{10A} &= 2\frac{\eta^3\eta(2)\eta(5)}{\eta(10)} = 2 - 6q - 2q^2 + 16q^3 - 2q^4 - 6q^5 - 8q^6 - 8q^7 - 2q^8 + 2q^9 + \cdots\,, \\
f_{11A} &= \frac{11}{6}E_2^{(11)} - \frac{22}{5}\eta^2\eta(11)^2 = \frac{11}{6} + 22q^2 + 22q^3 + 22q^4 + 22q^5 + 44q^6 + 44q^7 + 66q^8 + 66q^9 + \cdots\,, \\
f_{12A} &= 2\frac{\eta^3\eta(4)^2\eta(6)^3}{\eta(2)\eta(3)\eta(12)^2} = 2 - 6q + 2q^2 + 6q^3 - 6q^4 + 12q^5 - 10q^6 - 6q^8 - 6q^9 + \cdots\,, \\
f_{12B} &= 2\frac{\eta^4\eta(4)\eta(6)}{\eta(2)\eta(12)} = 2 - 8q + 6q^2 + 8q^3 - 4q^4 - 24q^6 + 16q^7 - 6q^8 + 16q^9 + \cdots\,, \\
f_{14AB} &= \frac{91}{36}E_2^{(14)} - \frac{7}{12}E_2^{(7)} - \frac{1}{36}E_2^{(2)} - \frac{14}{3}\eta\eta(2)\eta(7)\eta(14) \\
&= \frac{23}{12} - 3q + 11q^2 + 16q^3 + 11q^4 + 10q^5 + 16q^6 + 25q^7 + 39q^8 + 17q^9 + \cdots\,, \\
f_{15AB} &= \frac{35}{16}E_2^{(15)} - \frac{5}{24}E_2^{(5)} - \frac{1}{16}E_2^{(3)} - \frac{15}{4}\eta\eta(3)\eta(5)\eta(15) \\
&= \frac{23}{12} - 2q + 9q^2 + 13q^3 + 16q^4 + 13q^5 + 24q^6 + 14q^7 + 15q^8 + 28q^9 + \cdots\,, \\
f_{21AB} &= \frac{7}{3}\frac{\eta^3\eta(7)^3}{\eta(3)\eta(21)} - \frac{1}{3}\frac{\eta^6}{\eta(3)^2} = 2 - 5q - 3q^2 + 10q^3 + 7q^4 - 6q^5 - 12q^6 - 5q^7 + 6q^8 + 10q^9 + \cdots\,, \\
f_{23AB} &= \frac{23}{12}E_2^{(23)} - 69\eta^2\eta(23)^2 + 92\eta(2)^2\eta(46)^2 + 92\eta\eta(2)\eta(23)\eta(46) + 23\frac{\eta^3\eta(23)^3}{\eta(2)\eta(46)} \\
&= \frac{23}{12} + 23q^3 + 23q^4 + 23q^6 + 46q^8 + 23q^9 + \cdots\,.
\end{aligned}$$

Equation (7.16) of [13] tells us

$$\eta^3 q^{-1/8}\sum_{n=0}^{\infty} H_n(1)\,q^n = 48F^{(2)}(\tau) - 2E_2(\tau)\,, \tag{2.13}$$

where $F_2^{(2)}(\tau) = \sum_{n>m>0,n\not\equiv_2 m}(-1)^n m q^{mn/2}$. We read off from (2.12) and (2.13) that

$$E_2^{(2)} \equiv 1 \pmod{24}\,, \tag{2.14}$$

$$E_2^{(3)} \equiv 1 \pmod{12}\,, \tag{2.15}$$

$$\eta^3 q^{-1/8}\sum_{n=0}^{\infty} H_n(1)\,q^n \equiv -2 \qquad \pmod{48}\,. \tag{2.16}$$

These will be used in the Section 3 proofs. (We thank Thomas Creutzig and Gerald Höhn for bringing (2.13) and its consequence (2.16) to our attention.)

Lemma 1. [29] *Let* $g \in M_{24}$ *have order* $|g|$, *with parameter* h *given in Table 2. Then the twining character* $\phi_g(\tau, z)$ *is a Jacobi form of index 1 and weight 0 under* $\Gamma_0(|g|)$ *with multiplier defined by*

$$\phi_g\left(\frac{a\tau+b}{c\tau+d}, \frac{z}{c\tau+d}\right) = e^{2\pi i cd/(|g|\,h)} e^{2\pi i cz^2/(c\tau+d)} \phi_g(\tau, z)\,. \tag{2.17}$$

The function $f_g(\tau)$*is a holomorphic modular form of weight 2 for* $\Gamma_0(|g|)$ *with multiplier* $e^{2\pi i cd/(|g|\,h)}$, *i.e.* $f_g\left(\frac{a\tau+b}{c\tau+d}\right) = (c\tau+d)^2 e^{2\pi i cd/(|g|\,h)} f_g(\tau)\ \forall \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(|g|)$.

$\Gamma_0(n)$ as usual consists of all matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ with $n|c$. The appearance of both $\Gamma_0(|g|)$ and the multiplier in Lemma 1 are not at all mysterious, as explained in the concluding section.

Again, reversing the logic, we can use these conjectured expressions for ϕ_g to define class functions $H_{00}(g)$ and $H_n(g)$. It was checked by brute force that these class functions are in fact true characters, for all $n \leq 500$ (except H_0 and H_{00} which are merely virtual). This is our Theorem A.

One would certainly want more than weak Moonshine (Theorem A) — e.g. we should have an M_{24}-worth of twisted twining elliptic genera with nice modularity. This is now done [31]. Unlike Monstrous Moonshine, where the algebraic content comes from the VOA $V^\natural$, the algebraic (not to mention geometric and physical) meaning of K3-Mathieu Moonshine is still unclear. Although we have learned much in the two years or so since [24], we still don't really know the right questions to ask.

3 Weak K3-Mathieu Moonshine I: Integrality

In this section and the next, we prove Theorems A and B, which were stated in Section 2. Our proof falls into two independent steps: *integrality* (this section) and *positivity* (next section).

Let G be any finite group. Let $\mathcal{P}_G$ be the set of all pairs (p, K_g) where p is a prime dividing the order $|G|$, K_g is a *p-regular* conjugacy class in G (i.e. the order $|\langle g\rangle|$ of g is coprime to p), and p divides the order $|C_G(g)|$ of the centraliser. There are precisely 22 pairs in $\mathcal{P}_G$ for $G = M_{24}$, which we list in Table 3. For reasons to become clear shortly, we include the highest power p^π of p dividing $|C_G(g)|$, and the p'*-section* S which we define next paragraph.

Table 3. Data for virtual character proof

p	2	2	2	2	2	2	3	3	3	3	3	3	3	3	5	5	5	7	7	7	11	23

q^n	q^4	q^8	q^{48}	q^6	q^4	q^4	q^2	q^2	q^2	q^4	q^6	q^4	q^{16}	q^{16}	q^1	q^3	q^4	q^1	q^4	q^5	q^2	q^4

For any $h \in G$ of order $n = p^k m$, where $\gcd(p, m) = 1$, find $a, b \in \mathbb{Z}$ such that $1 = ap^k + bm$. Then $h = h_{p'} h_p$ where the *p'-part* $h_{p'} = h^{ap^k}$ has order m and the *p-part* $h_p = h^{bm}$ has order p^k. The p'-section S for the pair $(p, K_g) \in \mathcal{P}_G$ is defined to be $S = \{h \in G \,|\, h_{p'} \in K_g\}$. S is clearly the union of conjugacy classes; in Table 3 we list those conjugacy classes.

Suppose we have an integer-valued class function $c : G \to \mathbb{Z}$, i.e. c is constant on conjugacy classes. We are interested in H being one of the head characters H_n, and we want to prove it is the character of an M_{24}-representation. The hard part is to prove that A is a virtual character, i.e. a linear combination over $\mathbb{Z}$ of irreps. The starting point is the following characterisation of virtual characters, attributed to Thompson and based on the classical theorem of Brauer. It is a refinement of the following basic idea, which the reader can verify for himself: If χ is an integer-valued character and g is an element of order a prime power p^π, then $\chi(g) \equiv \chi(e) \pmod{p}$.

Choose any $(p, K_g) \in \mathcal{P}_G$ and write the p'-section S as a disjoint union $\cup_{i=1}^k K_i$ of conjugacy classes, for some k depending on (p, S). Let R_p be the tensor product $\widehat{\mathbb{Z}}_p \otimes_{\mathbb{Z}} \mathbb{Z}[\xi_{|G|}]$, where $\widehat{\mathbb{Z}}_p$ are the p-adic integers and $\xi_n = e^{2\pi \mathrm{i}/n}$. R_p is introduced to make formal sense of the orthogonality relations we're about to introduce; the ring $\mathbb{Z}[\xi_{|G|}]$ arises because all irreducible G-characters take values there. Define $\mathcal{M}_{(p,K_g)}$ to be the set of all k-tuples $(\ell_1, \ldots, \ell_k) \in R_p^k$ such that $\sum_{i=1}^k \ell_i \chi(K_i) \in p^\pi R_p$ for all irreducible characters χ. If c is a virtual character, then c is likewise orthogonal to $\mathcal{M}_{(p,S)}$. What is important to us is the converse:

Lemma 2. [48] *Let R_p and $\mathcal{M}_{(p,K_g)}$ be as above. Let $c : G \to \mathbb{Z}$ be an integer-valued class function of G. Then c is a virtual character of G, i.e. a linear combination over $\mathbb{Z}$ of irreducibles, if $\sum_{i=1}^k \ell_i c(K_i) \in p^\pi R_p$ for all $(\ell_1, \ldots, \ell_k) \in \mathcal{M}_{(p,K_g)}$ and all $(p, K_g) \in \mathcal{P}_G$.*

Of course we want to apply this to $c = H_n$, for each $n > 0$. The reason this characterisation is helpful is that much is known about reductions of modular forms modulo powers of primes, as we will see.

Suppose $f(\tau) = \sum_{n=0}^\infty f_n q^n, g(\tau) = \sum_{n=0}^\infty g_n q^n$ are holomorphic modular forms of weight $k \in \mathbb{Z}$ for some finite-index subgroup Γ and multiplier $\mu : \Gamma \to \mathbb{C}^\times$, and μ has finite order M. If the Fourier coefficients f_n, g_n are equal for all $n \leq k\|\mathrm{SL}_2(\mathbb{Z})/\Gamma\|/12$, then $f = g$. This is an immediate consequence of the classical valence formula for Γ applied to $(f - g)^M$. Incidentally, because of this and Lemma 1, the q-expansions provided earlier are more than enough to uniquely specify f_g (and hence ϕ_g) — in fact the coefficients $n \leq 5$ suffice. What is much more surprising is that this also applies to the modular forms mod prime powers:

Lemma 3. *Suppose $f(\tau) = \sum_{l \geq 0} f_l q^l \in \mathbb{Q}[[q^{1/N}]]$ and $g(\tau) = \sum_{l \geq 0} g_l q^l \in \mathbb{Q}[[q^{1/N}]]$ are holomorphic modular forms of rational weight $k \in \mathbb{Q}$ and with some multiplier μ for some subgroup Γ of $SL_2(\mathbb{Z})$. Let $m := \|\mathrm{SL}_2(\mathbb{Z})/\Gamma\|$ be the index. We require that μ has finite order, i.e. that all values $\mu(\gamma)$ for $\gamma \in \Gamma$ are Mth roots of 1 for some M.*

(a) *Suppose the Fourier coefficients f_l and g_l are integral for all l. Suppose we have an integer $n > 0$ such that $f_l \equiv g_l \pmod{n}$ for all $l \leq km/12$. Then $f_l \equiv g_l \pmod{p}$*

for all l.

(b) *Suppose now that the weight k is integral and that the kernel of μ is a congruence subgroup, i.e. contains $\Gamma(N')$ for some N'. If the coefficients f_l are integral for all $0 \leq l \leq km/12$, then $f_l \in \mathbb{Z}$ for all l.*

Proof. The key result upon which this Lemma rests is Sturm's Theorem [49], which is part (a) in the special case where the multiplier μ is trivial and the weight is integral and n is a prime (Sturm however allows the Fourier coefficients to be algebraic integers).

It suffices to prove the Lemma for $g = 0$. Start with part (a). Let p be any prime dividing n. Choose an integer $K > 0$ so that $Kk \in \mathbb{Z}$ and μ^K is identically 1. Then $F := f^K$ is a holomorphic modular form for Γ of integer weight Kk and trivial multiplier, whose Fourier coefficients F_l are multiples of the prime p for all $l \leq Kkm/12$ (since each F_l will be a sum of monomials in f_{l_i}'s at least one of which has $l_i \leq km/12$). Then Sturm's theorem applies, and we find that p divides *all* coefficients F_l. This must imply that p divides all coefficients of f (otherwise, choose the smallest l such that p doesn't divide f_l, and note that p would fail to divide F_{Kl}). This means that f/p will have integer coefficients, so f/p will obey all hypotheses of part (a) with now n replaced with n/p. Repeat with another prime dividing n/p, until you've reduced n to 1.

To see Lemma 3(b), let V be the space of all holomorphic weight k modular forms for $\Gamma(N')$ with trivial multiplier. V is finite-dimensional with an integral basis $f^{(i)} \in \mathbb{Z}[[q^{1/N'}]]$. Therefore we can write $f = \sum_i a_i f^{(i)}$ where $a_i \in \mathbb{Q}$. This means the coefficients of f have denominator bounded by the lcm of all denominators of the a_i. Let L be the smallest positive integer such that $Lf \in \mathbb{Z}[[q]]$. If p is a prime dividing L then p will divide the first $mk/12$ coefficients of Lf by the hypothesis on f, hence will divide all coefficients by Lemma 3(a), contradicting the minimality of L. This means $L = 1$, and we're done. **QED to Lemma 3**

Theorem 1. *Each H_n ($n \geq 1$) is a virtual character of M_{24} (i.e. a linear combination over $\mathbb{Z}$ of irreducible characters of M_{24}).*

Proof. First, we need to show the class functions H_n are integer-valued. We will do this by studying the f_g's. One complication is that the coefficients of $f_g(\tau)$ are not quite integers, as can be seen by the displayed values in Section 2. The problem is the constant term $\frac{1}{4}$ in the middle term of (2.11), and the 12 in the denominator of its first term. In fact only the constant term of $w_g\,(\theta_3^4 + \theta_4^4)/12 - w_g\theta_3\theta_4/4$ can fail to be integral. To see this, it suffices to show that $\theta_3\theta_4 \in 1 + 4q\mathbb{Z}[[q]]$ and $\theta_3^4 + \theta_4^4 \in 2 + 12q\mathbb{Z}[[q]]$. That these both hold modulo 4 follows from $\theta_3 = 1 + 2\sum + 2\sum'$ and $\theta_4 = 1 + 2\sum - 2\sum'$, using obvious notation. That $\theta_3^4 + \theta_4^4 \equiv 1$ (modulo 3) follows from comparing $(\theta_3^4 + \theta_4^4)^2$ and E_4 modulo 3, using Lemma 3 with $\Gamma = \Gamma(2)$.

From Lemma 3(b) and checking the integrality of the first few coefficients of f_g we learn now that all coefficients of $f_g - w_g\,(\theta_3^4 + \theta_4^4)/12 + w_g\theta_3^2\theta_4^2/4$ are integral (the theta function contribution kills the fractional part of the constant term). This means that all coefficients of each f_g are integral except possibly for the constant term, and also (from the first equality in (2.11)) that all coefficients of $\eta^3 q^{-1/8}\sum H_n(g)q^n$ are integral. Since $\eta^3 q^{-1/8}$ is invertible in the ring $\mathbb{Z}[[q]]$, we find that $H_n(g)\in\mathbb{Z}$ for all $n\geq 0$ and all $g\in M_{24}$.

This invertibility of $\eta^3 q^{-1/8}$ directly gives us the useful implication:

$$l f_g \in m\mathbb{Z}[[q]] \;\Rightarrow\; lH_n(g)\equiv l\frac{w_g}{24}H_n(1)\pmod{m} \tag{3.1}$$

for all $n\geq 0$, for any choice of $l,m\in\mathbb{Z}$ and all $g\in M_{24}$.

We need to verify, for each pair $(p,K_g)\in\mathcal{P}_{M24}$, that $\sum_{i=1}^{k}\ell_i H_n(K_i)\in p^\pi R_p$ for all $(\ell_1,\ldots,\ell_k)\in\mathcal{M}_{(p,K_g)}$.

A typical example is the pair $(3,2A)$. From Table 3 we see that $S=K_{2A}\cup K_{6A}$. Note that $\chi(2A)\equiv_3\chi(6A)$, for all irreducible χ, so we need to show $H_n(2A)\equiv_3 H_n(6A)$ for all n. We claim that $f_{2A}-4f_{6A}\in 3\mathbb{Z}[[q]]$. To see this, first note that $f_{2A}-4f_{6A}$ is a modular form for $\Gamma_0(6)$ with integer q-expansion and trivial multiplier, so by Lemma 3(a) it suffices to check that 3 divides the q^l-coefficient of $f_{2A}-4f_{6A}$ for all $0\leq l\leq 2$, which is trivial to do from the expansions collected in Section 2. By (3.1) or otherwise, this implies $H_n(2A)\equiv_3 H_n(6A)$ for all n and we're done. The pairs $(2,5A),(2,7AB),(3,2B),(3,4AC),(5,1A),(5,2B),(11,1A)$ are all handled similarly.

The pair $(3,5A)$ is also easy. Here $S=5A\cup 15A\cup 15B$, and we find $\mathcal{M}_{(3,5A)}=R_3$-span$\{(0,1,-1),(1,-1,0)\}$ using obvious notation. $H_n(15A)=H_n(15B)$ for all n follows from $f_{15A}=f_{15B}$; $H_n(5A)\equiv_5 H_n(15A)$ follows from $f_{5A}\equiv_3 4f_{15A}$, proved in the usual manner using $\Gamma_0(15)$. The pairs $(5,3A),(7,1A),(7,2A),(7,3B),(23,1A)$ are done similarly.

For $(3,7AB)$, we need $H_n(7AB)\equiv_3 H_n(21AB)$ for all n. Using (2.11), as well as the congruences (2.16),(2.15), this is equivalent to verifying that $4f_{7AB}-f_{21AB}\equiv_3 2E_2^{(3)}$, which by Lemma 3 for $\Gamma=\Gamma_0(63)$ requires checking up to q^{16}. For $(2,3A)$, $S=3A\cup 6A\cup 12A$ and $\mathcal{M}_{(2,3A)}=R_2$-span$\{(2,-2,0),(1,1,1)\}$, so we need to verify that $H_n(3A)\equiv_2 H_n(6A)$ and $H_n(3A)+H_n(6A)\equiv_8 2H_n(12A)$, for all n. Using now (2.14), this is equivalent to verifying that $f_{3A}\equiv_2 f_{6A}$ and $f_{3A}+9f_{6A}-2f_{12A}\equiv_8 -2E_2^{(2)}$. The former requires checking up to q^2 (use $\Gamma_0(6)$), while the latter requires checking up to q^8 (use $\Gamma_0(24)$). The pair $(2,3B)$ is handled similarly.

The pair $(3,1A)$ has $S=1A\cup 3A\cup 3B$ and $\mathcal{M}_{(3,1A)}=R_3$-span$\{(1,1,1),(0,9,3),(0,0,9)\}$, so we need to establish $H_n(1A)\equiv_3 H_n(3B)$ and $H_n(3A)\equiv_{27} 3H_n(3B)-2H_n(1A)$ for all n. These are equivalent to $f_{3B}\equiv_3 2E_2^{(3)}$ and $4f_{3A}-12f_{3B}\equiv_{27} 9E_2^{(3)}$.

Finally, $\mathcal{M}_{(2,1A)}$ is the span of $(1,1,1,1,1,1,1)$, $(-22,-6,2,2,-2,2,0)$, $(44,12,28,4,4,0,0)$, $(-24,8,24,8,0,0,0)$, $(-208,-16,16,0,0,0,0)$, $(448,64,0,0,0,0,0)$, using obvious notation. Therefore we need to verify

$$\begin{aligned}
&H_n(4C) \equiv H_n(8A) \pmod 2\,,\\
&H_n(4B) \equiv 2H_n(8A) - H_n(4C) \pmod 4\,,\\
&H_n(4A) \equiv H_n(4B) + 2H_n(4C) - 2H_n(8A) \pmod 8\,,\\
&H_n(2B) \equiv 3H_n(4A) + 4H_n(4B) + 2H_n(4C) + 8H_n(8A) \pmod{16}\,,\\
&H_n(2A) \equiv -H_n(2B) + 4H_n(4A) + 6H_n(4B) - 8H_n(8A) \pmod{64}\,,\\
&H_n(1A) \equiv 7H_n(2A) - 6H_n(2B) + 8H_n(4A) + 24H_n(4B) + 32H_n(4C) - 64H_n(8A) \pmod{1024}
\end{aligned}$$

for all n. These are equivalent to

$$\begin{aligned}
&2f_{4C} \equiv 2f_{8A} + E_2^{(2)} \pmod 4\,,\\
&f_{4B} \equiv 2f_{8A} - f_{4C} \pmod 4\,,\\
&f_{4A} \equiv f_{4B} + 2f_{4C} - 2f_{8A} \pmod 8\,,\\
&f_{2B} \equiv 3f_{4A} + 4f_{4B} + 2f_{4C} + 8f_{8A} + 8E_2^{(2)} \pmod{16}\,,\\
&f_{2A} \equiv -f_{2B} + 4f_{4A} + 6f_{4B} - 8f_{8A} \pmod{64}\,,\\
&7f_{2A} - 6f_{2B} + 8f_{4A} + 24f_{4B} + 32f_{4C} - 64f_{8A} \equiv 0 \pmod{1024}\,,
\end{aligned}$$

respectively, where all of these are modular forms for $\Gamma_0(16)$. *QED*

Refining this argument slightly gives us the evenness property stated in Theorem B. (Theorem B will follow from Theorem 2 and Theorem 3).

Theorem 2. *Each head character H_n is a linear combination over $\mathbb{Z}$ of*

$$\{2, 2\rho_1, \rho_2 + \overline{\rho_2}, \rho_3 + \overline{\rho_3}, 2\rho_4, 2\rho_5, 2\rho_6, \rho_7 + \overline{\rho_7}, \rho_8 + \overline{\rho_8}, 2\rho_9, \\ \rho_{10} + \overline{\rho_{10}}, 2\rho_{11}, 2\rho_{12}, 2\rho_{13}, 2\rho_{14}, 2\rho_{15}, 2\rho_{16}, 2\rho_{17}, 2\rho_{18}, 2\rho_{19}, 2\rho_{20}\}$$

Proof. Let χ be any M_{24}-class function, and $\rho \in \widehat{M_{24}}$. Write $\mathrm{mult}_\rho(\chi)$ for the multiplicity. Consider first ρ a *complex* character (i.e. $\overline{\rho} \ncong \rho$). We know that each $f_g(\tau) \in \mathbb{Q} + q\mathbb{Z}[[q]]$. The integrality of $H_n(g)$ for each n means that $\mathrm{mult}_\rho(H_n) = \mathrm{mult}_{\overline{\rho}}(H_n)$.

Much more difficult are the real M_{24}-irreps ρ (i.e. $\rho \cong \overline{\rho}$). Assume $\rho \neq 1, \rho_1$ for now. Define

$$M_\rho(\tau) := \sum_{n=0}^{\infty} \mathrm{mult}_\rho(H_n) q^n = -\sum_{K_g} |C_{M_{24}}(g)|^{-1} \overline{\rho(g)} f_g(\tau)\, q^{1/8} \eta(\tau)^{-3}\,, \tag{3.2}$$

using (2.11), where the second sum is over all conjugacy classes in M_{24}. We know from Theorem 1 that each $M_\rho(\tau) \in q\mathbb{Z}[[q]]$ (at least for $\rho \neq 1, \rho_1$). We want to show that in fact $M_\rho(\tau) \in 2q\mathbb{Z}[[q]]$. Of course we can ignore the constant terms of the f_g in the following.

First note from the M_{24} character table that $\rho(23A)$ and $\rho(23B)$ will be equal and integral. Also, the centraliser $C_{M24}(23AB)$ has odd order (namely, 23). Since

$f_{23AB}(\tau) \in \mathbb{Q}+q\mathbb{Z}[[q]]$, this means we can ignore the contribution of the classes $23AB$ to (3.2) — together they will contribute something in $\frac{2}{23}q\mathbb{Z}[[q]]$ and thus will not affect the value of $23M_i(\tau)$ modulo 2.

Identical arguments apply to the classes $21AB$ and $15AB$. The class $11A$ can likewise be ignored: its centraliser has odd order (namely 11), $\rho(11A) \in \mathbb{Z}$, and $f_{11A}(\tau) \in \mathbb{Q} + 2q\mathbb{Z}[[q]]$ (to see this, apply Lemma 3(a) to $\frac{1}{2}(f_{11A} + \frac{1}{6}E_2^{(11)})$). Finally, the classes $7AB$ and $14AB$ can all be dropped from (3.2): they all have the same order (namely 14) of centraliser, $\rho(7A) + \rho(7B) + \rho(14A) + \rho(14B) \in 4\mathbb{Z}$ (since $\overline{\rho} \cong \rho$), and the q^n-coefficients ($n > 0$) of f_{7AB} and f_{14AB} are integers congruent mod 2 (to see this, apply Lemma 3(a) to $3f_{14AB} - f_{7AB}$). Let $\widetilde{M_\rho}(\tau)$ be $23 \cdot 21 \cdot 5 \cdot 11$ times the sum in (3.2) restricted to the remaining classes $K_g \in \{1A, 2AB, 3AB, 4ABC, 5A, 6AB, 8A, 10A, 12AB\}$. Then $\widetilde{M_\rho}(\tau) \in q\mathbb{Z}[[q]]$ and $M_\rho \equiv_2 \widetilde{M_\rho}$ and we need to show that $\widetilde{M_\rho}(\tau) \in 2q\mathbb{Z}[[q]]$, or equivalently $\eta^3 q^{-1/8}\widetilde{M_\rho} \in 2q\mathbb{Z}[[q]]$.

Note that $\eta^3 q^{-1/8}\widetilde{M_\rho}$ is a linear combination (over $\mathbb{Q}$) of f_g with $\rho(g) \neq 0$ and $g \in \{1A, 2AB, 3AB, 4ABC, 5A, 6AB, 8A, 10A, 12AB\}$. Let N_ρ be the least common multiple of $h_g N_g$ over those g, where h_g is in Table 2 and N_g is the order of g. We know from Lemma 1 that f_g is a weight-2 modular form for $\Gamma_0(h_g N_g)$ with trivial multiplier, so $\eta^3 q^{-1/8}\widetilde{M_\rho}$ is a weight-2 modular form for $\Gamma_0(N_\rho)$ with trivial multiplier. We collect N_ρ in Table 4, together with the quantity $m_\rho/6$ where $m_\rho = \|\mathrm{SL}_2(\mathbb{Z})/\Gamma_0(N_\rho)\|$. By Lemma 3, we need to show that the first $m_\rho/6$ coefficients of $\eta^3 q^{-1/8}\widetilde{M_\rho}$ are even. As in (2.11) this is equivalent to showing that the first $m_\rho/6$ values of $\mathrm{mult}_\rho(H_n)$ are even. The evenness of these multiplicities $\mathrm{mult}_\rho(H_n)$ has been verified for all $n \leq 500$ and all real ρ, by Gaberdiel-Hohenegger-Volpato (private communication; see also [29]), which is far more than is necessary.

The proof for $\rho = 1$ and $\rho = \rho_1$ is similar, but (3.2) has to be modified. For those ρ define

$$\begin{aligned} F_\rho(\tau) &:= \sum_{K_g} |C_{M_{24}}(g)|^{-1}\overline{\rho(g)} f_g(\tau) + \frac{1}{12}E_2^{(2)}(\tau) \\ &= -q^{-1/8}\eta(\tau)^3 \sum_{n=0}^{\infty}\left(\mathrm{mult}_\rho(H_n) - \frac{1}{24}H_n(1)\right) q^n + \frac{1}{12}E_2^{(2)}(\tau) \\ &\equiv_2 -q^{-1/8}\eta(\tau)^3 \sum_{n=0}^{\infty}\mathrm{mult}_\rho(H_n)\, q^n\,, \end{aligned} \tag{3.3}$$

using (2.16), (2.14), (2.11) and the fact that $w_g = 1+\rho_1(g)$. Thus if we can show $F_\rho(\tau)$ has even coefficients, we will be done. The expression (3.3) together with Theorem 1 tells us F_ρ has integral Fourier coefficients. Define $\widetilde{F_\rho}$ as above by restricting the sum to classes $K_g \in \{1A, 2AB, 3AB, 4ABC, 5A, 6AB, 8A, 10A, 12AB\}$ and multiplying by $23 \cdot 21 \cdot 5 \cdot 11$; as above, it suffices to show the first 288 coefficients are even, equivalently that the multiplicities of both 1 and ρ_1 are even in all head characters

H_n for $n \leq 288$. This has been done in the aforementioned computer checks. **QED to Theorem 2**

4 Weak Mathieu Moonshine II: Positivity

In this section we prove that for each $n > 0$ and each irreducible $\rho \in \widehat{M_{24}}$, the multiplicities $\mathrm{mult}_{H_n}(\rho)$ are nonnegative. The difficult part of this positivity proof is effectively bounding a certain series (what we call $Z_{n;h}(3/4)$ below) which does not converge absolutely. There are (at least) two approaches for this: interpreting this as a Selberg-Kloosterman zeta function as in [47],[33], etc; or interpreting this as a sum over equivalence classes of quadratic forms as in Hooley [37]. The former method was used by [6] to prove convergence for the Rademacher sum expressions for the mock modular forms $q^{-1/8}\sum_{n=0}^{\infty} H_n(g)q^n$; the latter method (or rather its recent reincarnation [4]) was suggested in [19] as a way to prove convergence for $g = 1$. We need much more than convergence: we need an explicit bound, and for this we have found the second method more useful.

Let's begin with an elementary observation. By the triangle inequality,

$$\mathrm{mult}_{H_k}(\rho) = \sum_g \frac{H_k(g)}{|C_{M24}(g)|}\overline{\rho(g)} \geq \frac{H_k(1)}{|M24|}\rho(1) - \sum_{g\neq 1}\frac{|H_k(g)|}{|C_{M24}(g)|}|\rho(g)| \tag{4.1}$$

where the sum is over all conjugacy classes of M_{24}. Since there always is the trivial bound $\rho(1) \geq |\rho(g)|$ (which itself follows immediately from the triangle inequality), our strategy to show $\mathrm{mult}_{H_k}(\rho) > 0$ is to show $H_k(1)$ is much larger in modulus than the other character values $H_k(g)$, at least for k sufficiently large.

Choose any $g \in M_{24}$. Then from Lemma 1 we read that the multiplier of f_g is $\rho_{|g|;h_g}$, where $\rho_{n;h}$ sends $\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) \in \Gamma_0(n)$ to $e\left(\frac{cd}{nh}\right)$. The multiplier ϵ of η sends $\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ (with $c > 0$) to

$$\frac{1-\mathrm{i}}{\sqrt{2}}\omega_{-d,c}\, e\left(\frac{a+d}{24c}\right), \tag{4.2}$$

where

$$\begin{aligned}\omega_{d,c} &= \prod_{\mu=1}^{k} \exp(\pi \mathrm{i} \left(\left(\frac{h\mu}{k}\right)\right)\left(\left(\frac{\mu}{k}\right)\right)) \\ &= \begin{cases} \left(\frac{-d}{c}\right) e\left(\frac{-1}{8}(c-1) + \frac{-1}{24}(c-\frac{1}{c})(2d+d'-d^2d')\right) & \text{if } c \text{ is odd} \\ \left(\frac{-c}{d}\right) e\left(\frac{-1}{8}(2-cd-d) + \frac{-1}{24}(c-\frac{1}{c})(2d+d'-d^2d')\right) & \text{if } c \text{ is even}\end{cases}.\end{aligned} \tag{4.3}$$

Here, $((x)) = x - \lfloor x \rfloor - 1/2$ unless $x \in \mathbb{Z}$ in which case $((x)) = 0$. We write here d' for any solution to $dd' \equiv_c 1$. $\left(\frac{d}{c}\right)$ denotes the Jacobi symbol. The first expression for $\omega_{d,c}$ is the most familiar; the second (due to Rademacher [45]) is more useful for us.

We learn in eq.(6.1) of [6] (see also [19] for the special case $g = 1$) that

$$H_k(g) = \frac{4\pi}{(8k-1)^{1/4}} \sum_{c=1}^{\infty} \frac{1}{|g|\, c} I_{1/2}\left(\frac{\pi}{2c\,|g|}\sqrt{8k-1}\right) S(k, |g|\, c, \epsilon^{-3}\rho_{|g|;h_g})\,, \tag{4.4}$$

where $I_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sinh(x)$ and S is (up to a constant) a generalised Kloosterman sum for $\Gamma_0(|g|)$:

$$S(k, nc, \epsilon^{-3}\rho_{n;h}) = \sum_{\substack{0<d\le nc\\ \gcd(d,nc)=1}} \omega_{d,nc}^{-3} e\left(\frac{-cd}{h}\right) e\left(\frac{kd}{nc}\right) \tag{4.5}$$

Fix integers $n, h, k > 0$ and define $L = \frac{\pi}{n}\sqrt{2k-1}$ (so $\pi\sqrt{2k-1}/(2nc) < 1$ if $c > L$). We have the elementary bounds:

$$\left| I_{1/2}(x) - \sqrt{\frac{2x}{\pi}} \right| \le \frac{1}{5}\sqrt{\frac{2x^5}{\pi}} \qquad \text{for } 0 < x < 1\,; \tag{4.6}$$

$$|I_{1/2}(x)| < \frac{e^x}{\sqrt{2\pi x}} \qquad \text{for all } 0 < x\,; \tag{4.7}$$

$$|S(k, nc, \epsilon^{-3}\rho_{n;h})| \le 1 \qquad \text{for all } c \in \mathbb{Z}_{>0} \tag{4.8}$$

(in fact Lemma 6 below will give us the Weil bound $|S| \le O(\sqrt{c})$, but (4.8) is adequate). These inequalities immediately imply the crude bounds

$$\begin{aligned}
&\left| \frac{1}{(8k-1)^{1/4}} \sum_{c=2}^{\lfloor L \rfloor} \frac{1}{c} I_{1/2}\left(\frac{\pi\sqrt{8k-1}}{2nc}\right) S(k, nc, \epsilon^{-3}\rho_{n;h}) \right| \\
&\qquad \le \frac{\sqrt{n}}{\pi\sqrt{8k-1}} \sum_{c=2}^{\lfloor L \rfloor} \frac{1}{\sqrt{c}} e^{\pi\sqrt{8k-1}/(2nc)} < \frac{1}{\sqrt{2n}} e^{\pi\sqrt{8k-1}/(4n)}\,,
\end{aligned} \tag{4.9}$$

$$\begin{aligned}
&\left| \frac{1}{(8k-1)^{1/4}} \sum_{c=\lceil L \rceil}^{\infty} \frac{1}{nc} I_{1/2}\left(\frac{\pi\sqrt{8k-1}}{2nc}\right) S(k, nc, \epsilon^{-3}\rho_{n;h}) \right| \\
&\qquad \le \left| \sum_{c=\lceil L \rceil}^{\infty} (nc)^{-3/2} S(k, nc, \epsilon^{-3}\rho_{n;h}) \right| + \frac{\pi^2(8k-1)}{20n^{7/2}} \sum_{c=\lceil L \rceil}^{\infty} c^{-7/2} \\
&\qquad \le |Z_{n;h}(3/4)| + \frac{\pi\sqrt{8k-1}}{n^{5/2}} + \frac{7\pi^2(8k-1)}{80n^{7/2}}\,,
\end{aligned} \tag{4.10}$$

where $Z_{n;h}$ is the Selberg-Kloosterman zeta function

$$Z_{n;h}(s) = \sum_{c=1}^{\infty} S(k, nc, \epsilon^{-3}\rho_{n;h})\,(nc)^{-2s}\,. \tag{4.11}$$

Thus it suffices to find an effective bound for a Selberg-Kloosterman zeta function at $s = 3/4$. We know from [6] that the defining series (4.11) converges there, but it follows from Lemma 4 below that this convergence is not absolute, and in any event it seems difficult to use the analysis of [6] to obtain an explicit bound (as a function in k). The key first step in identifying such an effective bound is to rewrite these generalised Kloosterman sums more sparsely. Our calculation resembles that of [51]; a more elegant approach attributed to Selberg and worked out by Rademacher [46] is available but we were unable to generalise it to our context. Incidentally, Lemma 4 should imply that these S's have some multiplicative properties (hence their Z's have Euler-like products).

Lemma 4. *Let $c \in \mathbb{Z}_{>0}$, $k \in \mathbb{Z}$, $h|n$. Then*

$$S(k, nc, \epsilon^{-3}\rho_{n;h}) = \frac{-\mathrm{i}\sqrt{nc}}{2} \sum_{\substack{0\leq m<4nc \\ m^2\equiv_{8nc}1-8k+8c^2n/h}} e\left(\frac{m}{4nc}\right) . \tag{4.12}$$

Proof. We will begin with the proof of $n = h = 1$. Writing $m = 2\ell + 1$, define

$$B_c(k) := \frac{-\mathrm{i}\sqrt{c}}{2} \sum_{\substack{m=0 \\ m^2\equiv_{8c}1-8k}}^{4c-1} (-1)^{(m-1)/2} e\left(\frac{m}{4c}\right) = \frac{-\mathrm{i}\sqrt{c}}{2} e\left(\frac{1}{4c}\right) \sum_{\substack{\ell=0 \\ \ell^2+\ell\equiv_{2c}-2k}}^{2c-1} (-1)^{\ell} e\left(\frac{\ell}{2c}\right) .$$

As we manifestly have $B_c(k + c) = B_c(k)$ (i.e. B_c is a class function for $\mathbb{Z}_c$), we can formally write it as a combination of irreducible $\mathbb{Z}_c$-characters:

$$B_c(k) = \sum_{d=0}^{c-1} R_{d,c}\, e\left(\frac{dk}{c}\right) , \tag{4.13}$$

for coefficients

$$\begin{aligned} R_{d,c} &= \frac{-\mathrm{i}}{2\sqrt{c}} e\left(\frac{1}{4c}\right) \sum_{j=0}^{c-1} e\left(\frac{-dj}{c}\right) \sum_{\substack{\ell=0 \\ \ell^2+\ell\equiv_{2c}-2k}}^{2c-1} (-1)^{\ell} e\left(\frac{\ell}{2c}\right) \\ &= \frac{-\mathrm{i}}{2\sqrt{c}} e\left(\frac{1}{4c}\right) \sum_{\ell=0}^{2c-1} (-1)^{\ell} e\left(\frac{d\,(\ell^2+\ell)}{2c} + \frac{\ell}{2c}\right) . \end{aligned} \tag{4.14}$$

It is elementary to show that the sum on the right-side of (4.14) vanishes when $\gcd(c, d) > 1$: write $m = \gcd(c, d)$ and $\ell = s2c/m + r$, so $\sum_{\ell=0}^{2c-1} = \sum_{r=0}^{2c/m-1} \sum_{s=0}^{m-1}$, and notice that $\sum_s = 0$ for each r (when $m > 1$).

Thus we can restrict to $\gcd(c, d) = 1$. We want to show $R_{d,c} = \omega_{d,c}^{-3}$. Choose $d' \in \mathbb{Z}$ so that $1 = e\left(\frac{(dd'-1)(c+1)}{2c}\right)$; this permits us to rewrite (4.14) as

$$R_{d,c} = \frac{-\mathrm{i}e(1/4c)}{2\sqrt{c}} G(d, d\gamma; 2c) \tag{4.15}$$

where $\gamma := d'c + d' + 1$ and $G(a,b;c)$ is the generalised Gauss sum $G(a,b;c) = \sum_{\ell=0}^{c} e((a\ell^2 + b\ell)/c)$. Note that $\gamma := d'c + d' + 1$ is even iff c is even. When c is even, we can complete squares and obtain

$$\begin{aligned} R_{d,c} &= \frac{-\mathrm{i}\, e(1/4c)}{2\sqrt{c}}\, e\left(\frac{-d\gamma^2}{8c}\right) G(d,0;2c) \\ &= \left(\frac{2c}{d}\right) e\left(\frac{-(d-1)^2}{16} + \frac{2-c-d\gamma^2}{8c}\right). \end{aligned} \tag{4.16}$$

When c is odd, use $\frac{1}{2c} = \frac{-1}{2} + \frac{(c+1)/2}{c}$ to write $G(d, d\gamma; 2c) = G(-d, -d\gamma; 2)\, G(d(c+1)/2, d\gamma(c+1)/2; c)$; the left generalised Gauss sum equals 2, while the right is evaluated by completing squares as usual, and we obtain (for c odd)

$$R_{d,c} = \left(\frac{d(c+1)/2}{c}\right) e\left(\frac{(c-1)^2}{16} + \frac{2-2c-d(c+1)^3(d'+1)^2}{8c}\right). \tag{4.17}$$

Now, for m odd we have $\left(\frac{2}{m}\right) = (-1)^{(m^2-1)/8}$ and $\left(\frac{-1}{m}\right) = (-1)^{(m-1)/2}$. Consider first c even. Then directly from (4.3) and (4.16) we obtain

$$\frac{\omega_{d,c}^{-3}}{R_{d,c}} = e\left(\frac{-2-2c-d-d'-2cd+2dd'-c^2d+c^2d'+d^2d'+dd'^2+2cdd'^2+c^2dd'^2-c^2d^2d'}{8c}\right). \tag{4.18}$$

Because $dd' \equiv_{2c} 1$ when c is even we can define an integer L by $dd' = 1 + 2cL$, and we know that $d \equiv_4 d'$. Then (4.18) collapses to

$$\frac{\omega_{d,c}^{-3}}{R_{d,c}} = e\left(\frac{dL + d'L + 2L}{4}\right) = 1\,, \tag{4.19}$$

as desired. The proof for c odd is similar: the Jacobi symbol $\left(\frac{d(c+1)/2}{c}\right)$ equals $\left(\frac{2d}{c}\right)$; define L by $dd' = 1 + cL$ and use the congruences $c^3 \equiv_{8c} c$ and $4c^2 \equiv_{8c} 4c$.

Replacing c everywhere with nc establishes the $h = 1$ case of Lemma 4. Arbitrary $h|n$ is handled through the elementary observation that $S(k, nc, \epsilon^{-3}\rho_{n;h}) = S(k - c^2n/h, nc, \epsilon^{-3}\rho_{n;1})$. **QED to Lemma 4**

Hooley's method is based on the $n = 1$ case of Lemma 5 below; it was more recently modified slightly by [4]. We need a more serious revision. A binary quadratic form $Q(x,y) = \alpha x^2 + \beta xy + \gamma y^2 =: [\alpha, \beta, \gamma]$ is called *integral* if $\alpha, \beta, \gamma \in \mathbb{Z}$, and *positive-definite* if α and γ are both positive. (See e.g. Chapter 12 of [38] for a rather complete introduction to the basic theory of quadratic forms, as is relevant here.) The discriminant is $\beta^2 - 4\alpha\gamma$. For any $C \in \mathbb{Z}_{>0}$ and $D \in \mathbb{Z}_{<0}$, let $\mathcal{Q}(C, D)$ denote the set of all triples $(Q; r, s)$, where Q is integral and positive-definite with discriminant D and where r, s are coprime integers satisfying $Q(r,s) = C$. Any $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$ acts on $(Q; r, s) \in \mathcal{Q}(C, D)$ by sending $Q(x,y)$ to $Q(ax + by, cx + dy)$ and (r, s) to $(dr - bs, -cr + as)$. In particular, it is easy to verify that if $(Q; r, s)$ and $(Q'; \tilde{r}, \tilde{s})$ are in the same $\mathrm{SL}_2(\mathbb{Z})$-orbit then Q, Q' have the same discriminant and $Q(r,s) = Q'(\tilde{r},\tilde{s})$. Then Hooley observes that there is a bijection between the integers $0 \leq m < 2C$ satisfying $m^2 \equiv_{4C} 1$, and $\mathrm{SL}_2(\mathbb{Z})$-orbits in $\mathcal{Q}(C,D)$.

We need to generalise this in two ways. First, choose any integer $n \geq 1$. Write $\mathcal{Q}_n(C,D)$ denote the set of all triples $(Q;r,ns)$, where $Q = [n\alpha,\beta,\gamma]$ is positive-definite and of discriminant D, $\alpha,\beta,\gamma,r,s \in \mathbb{Z}$, $\gcd(r,ns) = 1$, and $Q(r,ns) = nC$. For example, $\mathcal{Q}(C,D) = \mathcal{Q}_n(C,D)$. It is elementary to show that the group $\Gamma_0(n)$ acts on $\mathcal{Q}_n(C,D)$.

Secondly, suppose that h divides $\gcd(n,24)$ and that $\gcd(n/h-1,h) = 1$. Write $n' = n/h$. Let $\mathcal{Q}_{n;h}(C,D)$ denote the set of all triples $(Q;r,ns)$ where $Q = [n\alpha,\beta,\gamma/h]$ is positive-definite and of discriminant D, $\alpha,\beta,\gamma,r,s \in \mathbb{Z}$, $\gamma \equiv_h \alpha$, $\gcd(r,n's) = 1$, and $Q(r,ns) = C$. Of course $\mathcal{Q}_{n;1}(C,D) = \mathcal{Q}_n(C,D)$. Recall the group $\Gamma_0(n|h)$, which can be defined equivalently as either the conjugate of $\Gamma_0(n')$ by $\left(\begin{smallmatrix} h & 0 \\ 0 & 1 \end{smallmatrix}\right)$, or as the set of all determinant-1 matrices of the form $\left(\begin{smallmatrix} a & b/h \\ nc & d \end{smallmatrix}\right)$ for $a,b,c,d \in \mathbb{Z}$. Let $\Gamma_0(n;h)$ denote the set of all $\left(\begin{smallmatrix} a & b/h \\ nc & d \end{smallmatrix}\right) \in \Gamma_0(n|h)$ for which $ac \equiv_h bd$. Then it is easy to verify $\Gamma_0(n;h)$ is a group, and we see shortly that it acts on $\mathcal{Q}_{n;h}(C,D)$.

The reason 24 arises here (and elsewhere) is because, for any divisor d of 24, any integer ℓ coprime to d satisfies $\ell^2 \equiv_d 1$. The defining condition $ac \equiv_h bd$ of $\Gamma_0(n;h)$ is equivalent to requiring that there is some ℓ (depending on a,b,c,d) coprime to h with $a \equiv_h \ell d$ and $b \equiv_h \ell$. To see this equivalence, run through each prime power p^ν exactly dividing h; the determinant condition $ad - n'bc = 1$ tells us that either a and d are both coprime to h (in which case require $\ell \equiv ad \pmod{p^\nu}$), or b,c are both coprime to h (in which case take $\ell \equiv bc \pmod{p^\nu}$). Then $a \equiv_{p^\nu} \ell d$ resp. $b \equiv_{p^\nu} \ell c$, and the other congruence comes from $ac \equiv_{p^\nu} bd$. Running through all p, we obtain an ℓ defined mod h which has all the desired properties.

Lemma 5(a) *Let $D \in \mathbb{Z}_{<0}$, $C \in \mathbb{Z}_{>0}$. There is a one-to-one correspondence between the set of integers m, $0 \leq m < 2nC$, satisfying $m^2 \equiv D \pmod{4nC}$, and $\Gamma_0(n)$-orbits in $\mathcal{Q}_n(C,D)$.*

(b) *There is a one-to-one correspondence between the set of integers m, $0 \leq m < 2nC$, satisfying $m^2 \equiv D + 4C^2n' \pmod{4nC}$, and $\Gamma_0(n;h)$-orbits in $\mathcal{Q}_{n;h}(C,D)$.*

Proof. Let's begin with the simpler part (a). First note that there is an obvious bijection between each $m \in \mathbb{Z}$ with $m^2 \equiv_{4nC} D$, and each quadratic form $Q = [nC,m,\gamma]$ (necessarily positive-definite) of discriminant D, where $\gamma = (m^2-D)/(4nC)$.

Given any $(Q;r,ns) \in \mathcal{Q}_n(C,D)$, $Q = [n\alpha,\beta,\gamma]$, choose any $\tilde{r},\tilde{s}$ such that $\begin{pmatrix} r & \tilde{r} \\ ns & \tilde{s} \end{pmatrix} \in \Gamma_0(n)$ (this is possible since $\gcd(r,ns) = 1$), and define the *root* $m := 2n\alpha r\tilde{r} + \beta\,(r\tilde{s} + ns\tilde{r}) + 2\gamma ns\tilde{s}$. Then $\begin{pmatrix} r & \tilde{r} \\ ns & \tilde{s} \end{pmatrix} \in \Gamma_0(n)$ sends $(Q;r,ns)$ to $([nC,m,\gamma'];1,0)$ where $\gamma' = (m^2-D)/(4nC)$. The other choices of $\tilde{r},\tilde{s}$ are $\tilde{r} + Lr, \tilde{s} + Lns$ for any $L \in \mathbb{Z}$, which correspond to roots $m + L2nC$, and so the root taken mod $2nC$ is a well-defined function $m(Q;r,ns) \in \mathbb{Z}_{2nC}$ on $\mathcal{Q}_n(C,D)$. The desired bijection in part (a) is this root map (mod $2nC$).

Now turn to part (b). Here, there is an elementary bijection between each $m \in \mathbb{Z}$ with $m^2 \equiv_{4nC} D + 4n'C^2$, and each positive-definite quadratic form $Q = [nC, m, \gamma/h]$ of discriminant D, where $\gamma \equiv_h C$. Choose any $([n\alpha, \beta, \gamma/h]; r, ns) \in \mathcal{Q}_{n;h}(C, D)$. Then $\left(\begin{smallmatrix} a & b/f \\ nc & d \end{smallmatrix}\right) \in \Gamma_0(n|h)$ will send (r, ns) to $(ra + n'sb, nrc + nsd)$ (the desired form), and $[n\alpha, \beta, \gamma/h]$ to

$$[n(\alpha a^2 + \beta ac + n'\gamma c^2), 2n'\alpha ab + \beta\,(ad + n'bc) + 2\gamma n'cd, (n'\alpha b^2 + \beta bd + \gamma d^2)/h]\,. \quad (4.20)$$

Then (4.20) will lie in $\mathcal{Q}_{n;h}(C, D)$ if

$$a^2 \equiv_h d^2\,, \quad ac \equiv_h bd\,, \quad n'c^2 \equiv_h n'b^2\,. \quad (4.21)$$

As explained above, the condition $ac \equiv_h bd$ is equivalent to the existence of an ℓ coprime to h satisfying $a \equiv_h \ell d$ and $b \equiv_h \ell c$, and such an ℓ forces the other two congruences to be satisfied. In other words, the matrices in $\Gamma_0(n|h)$ satisfying (4.21) form the group $\Gamma_0(n; h)$.

Since r and $n's$ are coprime, we can find integers $\tilde{r}, \tilde{s}$ such that $r\tilde{s} - n's\tilde{r} = 1$. We claim there is some $L \in \mathbb{Z}$, unique modulo h, such that $\left(\begin{smallmatrix} r & (Lr+\tilde{r})/h \\ ns & Ln's+\tilde{s} \end{smallmatrix}\right) \in \Gamma_0(n; h)$. To see this, choose any prime power p^ν exactly dividing h. If r is coprime to p choose $\ell \equiv_{p^\nu} 1 - n's^2$ and $L \equiv_{p^\nu} r'\,(-\tilde{r} + \ell s)$ where $r'r \equiv_{p^\nu} 1$; otherwise, $n's$ will be coprime to p, so choose s' by $s'n's \equiv_{p^\nu} 1$, $\ell_{p^\nu} r^2 - n'$, and $L \equiv_{p^\nu} s'\,(-\tilde{s} + \ell r)$. We are using here that $1 - n'$ is coprime to h and hence p. Then ℓ and L are defined mod h by running through all p. To see uniqueness of L modulo h, note that $\left(\begin{smallmatrix} r & (Lr+\tilde{r})/h \\ ns & Ln's+\tilde{s} \end{smallmatrix}\right)\left(\begin{smallmatrix} r & (L'r+\tilde{r})/h \\ ns & L'n's+\tilde{s} \end{smallmatrix}\right)^{-1} = \left(\begin{smallmatrix} 1 & (L-L')/h \\ 0 & 1 \end{smallmatrix}\right) \in \Gamma_0(n; h)$ forces $(L - L')/h \in \mathbb{Z}$ by definition of $\Gamma_0(n; h)$.

So we may assume $\left(\begin{smallmatrix} r & \tilde{r}/h \\ ns & \tilde{s} \end{smallmatrix}\right) \in \Gamma_0(n; h)$. Define the root $m := 2n'\alpha r\tilde{r} + \beta\,(r\tilde{s} + n's\tilde{r}) + 2\gamma n's\tilde{s}$ as before. Then $\begin{pmatrix} r & \tilde{r}/h \\ ns & \tilde{s} \end{pmatrix}$ sends $(Q; r, ns)$ to $([nC, m, \gamma']; 1, 0) \in \mathcal{Q}_{n;d}(C, D)$ where $\gamma' = (m^2 - D)/(4nC)$. From the uniqueness of the previous paragraph, we have that $\left(\begin{smallmatrix} r & (Lr+\tilde{r})/h \\ ns & Ln's+\tilde{s} \end{smallmatrix}\right) \in \Gamma_0(n; h)$ iff $L \in h\mathbb{Z}$, which corresponds to root $m + L2nC$, and so again the root taken mod $2nC$ is a well-defined function $m(Q; r, ns) \in \mathbb{Z}_{2nC}$ on $\mathcal{Q}_{n;d}(C, D)$. **QED to Lemma 5**

We are interested in $D = 1 - 8k$, $n = 2n_g$, $h = h_g$ and $C = c$. Restrict attention here to $k \geq 1$ (not a problem since we are only interested in large k), so $D < 0$. In fact, to sharpen slightly some of our bounds, we'll choose $k \geq 5$. Continue to write $n' = n/h$.

Note that if both $(Q; r, ns), (Q; \tilde{r}, n\tilde{s})$ (same Q) lie in $\mathcal{Q}_{n;k}(C, D)$, then there is an automorphism $g \in \Gamma_0(n; k)$ of Q sending (r, ns) to $(\tilde{r}, n\tilde{s})$. For $D < 0$ (the case we are interested in), each such automorphism g must have finite order (since completing squares in $\alpha = \alpha a^2 + \beta ac + n'\gamma c^2$ and $\gamma = n'\alpha b^2 + \beta bd + \gamma d^2$ bounds the matrix entries a, b, c, d of g). Now, $\Gamma_0(n|h)$ (which contains $\Gamma_0(n; h)$) is conjugate to

$\Gamma_0(n')$, so all of its elements of finite order have orders 2, 4, 6. In fact for us, the stabiliser $\mathrm{stab}([n\alpha,\beta,\gamma/h];\Gamma_0(n;h))$ of $[n\alpha,\beta,\gamma/h]$ in $\Gamma_0(n;h)$ will always be ± 1. To see this, first note $\mathrm{stab}([n\alpha,\beta,\gamma/h];\Gamma_0(n;h))$ is a subgroup of $\mathrm{stab}([n\alpha,\beta,\gamma/h];\Gamma_0(n|h))$, which is isomorphic to $\mathrm{stab}([n'\alpha,\beta,\gamma];\Gamma_0(n;h))$, which is in turn a subgroup of $\mathrm{stab}([n'\alpha,\beta,\gamma];\mathrm{SL}_2(\mathbb{Z}))$. For a *primitive* form $[n'\alpha,\beta,\gamma]$ (i.e. when $n'\alpha,\beta,\gamma$ don't have a common factor), nontrivial stabilisers occur only for discriminant $D=-3,-4$. But our discriminant satisfies $D\equiv 1 \pmod 8$, so even if $[n'\alpha,\beta,\gamma]$ is imprimitive, it can never have a nontrivial stabiliser in $\mathrm{SL}_2(\mathbb{Z})$.

We also need a bound on $\Gamma_0(n;h)$-equivalence class representatives $[n\alpha,\beta,\gamma/h]$. For this purpose, observe that $\Gamma_0(n;h)$ contains $\Gamma_0(nh)$, which has finite index $nh\prod_p(1+1/p)$ in $\mathrm{SL}_2(\mathbb{Z})$. The cosets for $\Gamma_0(N)\backslash\mathrm{SL}_2(\mathbb{Z})$ are in bijection with pairs $(c,d)\in\mathbb{Z}^2_{>0}$ where $c|N$ and $1\leq d\leq N/c$ satisfies $\gcd(d,c,N/c)=1$. To any such pair (c,d), a representative of that coset is $\left(\begin{smallmatrix} a & b \\ c & d'\end{smallmatrix}\right)$ where d' is coprime to c and satisfies $d'\equiv_{N/c} d$, and a,b are any integers satisfying $ad'-bc=1$. Now, $c=N$ corresponds to the identity coset, so for it take $c=0$ instead; then in all cases we have $c\leq N/2$. We can always choose $|a|\leq c/2$ by adjusting b appropriately (at least when $c\neq 0$), hence $|a|\leq N/4$ (true even for $c=0$ unless $N<4$). Now, over $\mathrm{SL}_2(\mathbb{Z})$, any positive-definite discriminant D quadratic form (with coefficients in $h^{-1}\mathbb{Z}$) is equivalent to some $[\alpha',\beta',\gamma']$ (namely Gauss' reduced form) with $|\beta'|\leq\alpha'\leq\gamma'$, where $\alpha'\leq\sqrt{|D|/3}$ and $\gamma'\leq 11h|D|/39$. Combining with (4.20), and noting that we can always force $|\beta|\leq n\alpha$ by applying multiples of $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1\end{smallmatrix}\right)\in\Gamma_0(nh)$, we see that any such quadratic form is equivalent over $\Gamma_0(nh)$, hence over $\Gamma_0(n;h)$, to some $[n\alpha,\beta,\gamma/h]$ satisfying the (crude but adequate) bounds

$$0<\alpha\leq\frac{n^2h^2}{16n}\left(3\sqrt{\frac{|D|}{3}}+44h|D|/39\right)<\frac{1}{12}nh^3\,|D|\,, \tag{4.22}$$

$$|\beta|<n^2h^3\,|D|/12\,, \tag{4.23}$$

$$0<\gamma\leq(|D|+\beta^2)/(4n'\alpha)<\begin{cases}|D|/7 & \text{if } n=2\\ n^2h^4\,|D|/44 & \text{otherwise}\end{cases}. \tag{4.24}$$

(The given bound on α, hence β, is also true for the identity coset $c=0$.) Implicit in these derivations are $2h\leq n$, n even, and $|D|\geq 39$.

The point is that the series $Z_{n;h}(3/4)$ can be rewritten as a sum over the finitely many $\Gamma_0(n;h)$-orbit representatives $[n\alpha,\beta,\gamma/h]$, and over integers r,s. Over-counting by a factor of 2, we can take this to be a free sum over r,s.

Theorem 3. *Choose any $k,n\in\mathbb{Z}_{>0}$, $k\geq 5$, and any h dividing gcd$(n,24)$ such that gcd$(n/h-1,2h)=1$. Then for $n\neq 2$,*

$$\begin{aligned}\left|Z_{n/2;h}(3/4)\right|\leq{}&\left(\prod_{p|(nh)}\frac{p+1}{p}\right)\left(1+2.13|D|^{1/8}\log|D|\right)\times\\ &\big((6.124n^{35/6}h^{47/6}-3.09n^{23/4}h^{31/4}+64.32n^{29/6}h^7-23n^{19/4}h^7)|D|\\ &+(.146n^{47/6}h^{65/6}-.114n^{31/4}h^{43/4}+2.51n^{35/6}h^{10}-.74n^{23/4}h^{10})|D|^{3/2}\big)\ .\end{aligned}$$

where we write $D = 1-8k$*. For* $n = 2$*, this bound on the right-side should be replaced with* $(3872|D| + 213|D|^{3/2})(1 + 2.13|D|^{1/8}\log|D|)$*.*

Proof. Note the n in the statement of Theorem 3 agrees with that of Lemma 5, but is twice that of Lemma 4. We need to bound the limit as $X \to \infty$ of

$$Z_{n/2;h}(s;X) = \sum_{c=1}^{X} S(k, nc, \epsilon^{-3}\rho_{n/2;h})\,(nc/2)^{-2s}\,. \tag{4.25}$$

Thanks to Lemmas 4 and 5, we can write its value at $s = 3/4$ as

$$\frac{-\mathrm{i}}{2}\sum_{[n\alpha,\beta,\gamma/h]}\ \sum_{c(\alpha,\beta,\gamma;r,s)\leq X}{}' \frac{(-1)^{(m(\alpha,\beta,\gamma;r,s)-1)/2}}{nc(\alpha,\beta,\gamma;r,s)}\, e\left(\frac{m(\alpha,\beta,\gamma;r,s)}{2n\,c(\alpha,\beta,\gamma;r,s)}\right)\,, \tag{4.26}$$

where the first sum is over representatives of the $\Gamma_0(n;h)$-orbits of positive-definite quadratic forms of discriminant $D = 1-8k$, and the second sum is over all integers r, s satisfying $\gcd(r, n's) = 1$ and the given inequality (the prime on the sum denotes that coprime condition). The quantities m, c are defined by

$$m(\alpha,\beta,\gamma;r,s) = 2n'\alpha r\tilde{r} + \beta\,(r\tilde{s} + n's\tilde{r}) + 2\gamma n's\tilde{s}\,,\ \ c(\alpha,\beta,\gamma;r,s) = \alpha r^2 + \beta rs + n'\gamma s^2\,,$$

where $\tilde{r}, \tilde{s}$ are any integers satisfying $\left(\begin{smallmatrix} r & \tilde{r}/h \\ ns & \tilde{s}\end{smallmatrix}\right) \in \Gamma_0(n;h)$ — which pair is chosen won't affect the value of that summand. The factor of 2 in (4.26) comes from the aforementioned redundancy that different (r, ns) can lie in the same orbit.

Write this inner sum $\sum_{r,s}$ (for each choice of α, β, γ) as $\sum_{>} + \sum_{<}$, depending on whether or not $|r| > n|s|$ ($|r| = n|s|$ would contradict $\gcd(r,s) = 1$) . We will bound $Z_{n/2;h}(3/4;X)$ by considering separately the contributions of $\sum_{>}, \sum_{<}$.

The arguments for $\sum_{>}$ and $\sum_{<}$ are completely analogous, and so we will consider in detail only $\sum_{>}$. Since then $r > 0$, we can write

$$\frac{m}{2nc} = \frac{2n'\tilde{r}\,(\alpha r^2 + \beta rs + n'\gamma s^2) + 2n'\gamma s + \beta r}{2nr\,(\alpha r^2 + \beta rs + n'\gamma s^2)} \equiv_1 -\frac{us'}{R} + \frac{2n'\gamma s + \beta r}{2nr\,(\alpha r^2 + \beta rs + n'\gamma s^2)} \tag{4.27}$$

where $\delta = \gcd(s,h)$, $h' = h/\delta$, $R = rh'$, $s' \in \mathbb{Z}$ is any inverse of s/δ mod R, and $u \in \mathbb{Z}$ is defined mod R by $u \equiv_r -\delta^{-1}(n')^{-1}$, $u \equiv_{h'} 1 - s^2n'$, and (if $3|\gcd(r,h)$) $u \equiv_9 -(n')^{-1}$ (note that $\gcd(r,h) \neq 1$ implies it equals 3, in which case s is coprime to 3 and $n' \equiv_3 -1$). Writing

$$\alpha r^2 + \beta rs + n'\gamma s^2 = n'\gamma\,(s + \frac{\beta r}{2n'\gamma})^2 - \frac{Dr^2}{4n'\gamma} = \alpha\,(r + \frac{\beta s}{2\alpha})^2 - \frac{Ds^2}{4\alpha}\,, \tag{4.28}$$

the first inequality gives

$$|r| \leq \sqrt{\frac{X4n'\gamma}{|D|}} = C\sqrt{X}\,, \qquad S_- \leq s \leq S_+\,, \tag{4.29}$$

where $C = \sqrt{4n'\gamma/|D|}$ and

$$S_+ = \min\left\{\frac{|r|}{n}, -\frac{\beta r}{2n'\gamma} + \frac{1}{2n'\gamma}\sqrt{4n'\gamma X + Dr^2}\right\}, \tag{4.30}$$

$$S_- = \max\left\{-\frac{|r|}{n}, -\frac{\beta r}{2n'\gamma} - \frac{1}{2n'\gamma}\sqrt{4n'\gamma X + Dr^2}\right\}. \tag{4.31}$$

We compute

$$(-1)^m = (-1)^{n'(\alpha r\tilde{r} + \beta s\tilde{r} + \gamma s\tilde{s}) + (\beta-1)/2} = (-1)^{(\beta-1)/2} \tag{4.32}$$

using the evenness of n' and the determinant relation $r\tilde{s} - n's\tilde{r} = 1$ (β is odd because of the discriminant condition $\beta^2 - 4n'\alpha\gamma = 1 - 8k$). Now put

$$\varphi(r,s) = \frac{(-1)^{(\beta-1)/2}}{\alpha r^2 + \beta rs + \gamma n's^2}\, e\left(\frac{2n'\gamma s + \beta r}{2nr\left(\alpha r^2 + \beta rs + \gamma n's^2\right)}\right); \tag{4.33}$$

we need to bound

$$\sum_{>} = \sum_{|r| \le C\sqrt{X}} \sum_{\delta | h} \sideset{}{'}\sum_{\substack{S_- \le s \le S_+ \\ \gcd(s,h)=\delta}} e\left(\frac{us'}{hr/\delta}\right)\varphi(r,s) = \sum_{|r| \le C\sqrt{X}} \sum_{\delta | h} \sum_{\substack{S_-/\delta \le S \le S_+/\delta \\ \gcd(S,R)=1}} e\left(\frac{uS'}{R}\right)\varphi(r,\delta S), \tag{4.34}$$

where we use (4.27), we write $R = hr/\delta$ as before and $S' = s'$ is any inverse of S mod R. Rewrite the sum over S in (4.34) (for fixed $\alpha, \beta, \gamma, r, \delta$) using partial summation (the discrete analogue of integration by parts):

$$\begin{aligned}\sideset{}{'}\sum_{S_-/\delta \le S \le S_+/\delta} e\left(\frac{uS'}{R}\right)\varphi(r,\delta S) &= \sum_{S_-/\delta \le \sigma \le S_+/\delta} g(\sigma)\left(\varphi(r,\delta\sigma) - \varphi(r,\delta\sigma+\delta)\right) \\ &\quad + g(\lfloor S_+/\delta \rfloor)\,\varphi(r,\delta\lfloor S_+/\delta\rfloor),\end{aligned} \tag{4.35}$$

where

$$g(\sigma) = \sideset{}{'}\sum_{\substack{S_-/\delta \le S \le \sigma \\ \gcd(S,R)=1}} e(uS'/R) \tag{4.36}$$

denotes the *incomplete* Kloosterman sums (R is implicit). We have (for $n > 2$)

$$\begin{aligned}|\varphi(r,s) - \varphi(r,s+\delta)| &\le \frac{16n'^2\gamma^2\delta}{D^2r^4}\left|\frac{|r|}{2}\sqrt{|D|} + n'\gamma\delta\right| + \frac{2\pi}{2n|r|}\frac{(4n'\gamma)^2}{|D|r^2}\frac{2}{2|r|\sqrt{|D|}} \\ &\le .0042\frac{n^6h^6}{|r|^3}\delta\sqrt{|D|} + .000188\frac{n^9h^9}{r^4}\delta^2|D| + .0083\frac{n^5h^6}{r^4}\sqrt{|D|},\end{aligned} \tag{4.37}$$

$$|\varphi(r,\delta\lfloor S_+/\delta\rfloor)| \le 4n'\gamma/(|D|r^2) \le .091n^3h^3r^{-2}, \tag{4.38}$$

where we use repeatedly (4.28), as well as Taylor's remainder $|e(\theta) - 1| \le 2\pi\theta_0$ for $|\theta| \le \theta_0$, and the elementary bound $x/(x^2+a^2) \le 1/(2|a|2)$. Thus all that remains is to bound $g(\sigma)$. The order of its growth with $|R|$ is stated (without proof) in Lemma 3 of [37]; an effective bound is:

Lemma 6. *For any integers k, u, h_1, h_2 with $h_1 \leq h_2$, we have*

$$\left|\sum_{h_1\leq h\leq h_2}{}' e\left(\frac{uh'}{k}\right)\right| < \left(\frac{k+h_2-h_1}{k}+2+2\ln(k)\right)\sqrt{k}\sqrt{\gcd(u,k)}\,d(k)\,, \tag{4.39}$$

where h' denotes the inverse of h (mod k) and the prime over the summation means to restrict to gcd$(h,k)=1$.

Proof. Assume for now that $h_2-h_1<k$. For any integer h, $h_1\leq h\leq h_1+k-1$, the map sending h to

$$\left(\left(\frac{h-h_2-1/2}{k}\right)\right)-\left(\left(\frac{h-h_1+1/2}{k}\right)\right)+\frac{h_2-h_1+1}{k}=\left\lfloor\frac{h-h_1+1/2}{k}\right\rfloor-\left\lfloor\frac{h-h_2-1/2}{k}\right\rfloor$$

equals 1 for $h_1\leq h\leq h_2$ and 0 otherwise. Now, we claim that for $0<x<1$,

$$\left|((x))+\sum_{j=1}^{k}\frac{\sin(2\pi jx)}{\pi j}\right|<\frac{1}{2k\min(x,1-x)}\,. \tag{4.40}$$

To see this, it suffices to consider $0<x\leq 1/2$. Write $K(x)=1+2\sum_{j=1}^{k}\cos(2\pi jx)=\sin(\pi\,(2k+1)x)/\sin(\pi x)$; then

$$((x))+\sum_{j=1}^{k}\frac{\sin(2\pi jx)}{\pi j}=\int_0^x K(y)dy-1/2=-\int_x^{1/2}K(y)dy \tag{4.41}$$

$$=\frac{-1}{\pi\,(2k+1)}\frac{\cos(\pi\,(2k+1)x)}{\sin(\pi x)}+\frac{1}{2k+1}\int_x^{1/2}\frac{\cos(\pi\,(2k+1)y)}{\sin^2(\pi y)}dy\,. \tag{4.42}$$

Since $\sin(\pi t)\geq 2t$ for $0\leq t\leq 1/2$, we get

$$\left|((x))+\sum_{j=1}^{k}\frac{\sin(2\pi jx)}{\pi j}\right|\leq\frac{1}{2\pi\,(2k+1)x}+\frac{1}{4\,(2k+1)x} \tag{4.43}$$

which implies the weaker (4.40).

Write $S(v,u;k)$ for the (complete) Kloosterman sum $\sum'_{1\leq h\leq k}e((vh+uh')/k)$ where the prime denotes restricting the sum to $\gcd(h,k)=1$. Then e.g. Lemma 2 of [36] gives an effective bound for it:

$$|S(v,u;k)|\leq\sqrt{k}\sqrt{\gcd(u,k)}\,d(k)\,. \tag{4.44}$$

Finally, it is elementary that $\sum_{j=1}^{k} 1/j \leq 1 + \ln(k)$. Therefore, putting all this together, we obtain

$$\left|{\sum_{h=h_1}^{h_2}}' e\left(\frac{h'}{k}\right)\right| \leq \frac{h_2 - h_1 + 1}{k}|S(0,u;k)| + \left|\sum_{j=1}^{k} \frac{e(-(k+1/2)j/k) - e(-j/(2k))}{2\pi j} S(j,u;k)\right|$$
$$+ 2\sum_{j=1}^{k/2} \frac{1}{2k\,(j-1/2)/k} \leq \frac{h_2 - h_1 + 1}{k}\sqrt{k}\sqrt{\gcd(u,k)}\, d(k)$$
$$+ \frac{1}{\pi}\sqrt{k}\sqrt{\gcd(u,k)}\, d(k)(1+\ln(k)) + (1+\ln(k))\,. \tag{4.45}$$

That the inequality (4.39) also holds when $h_2 - h_1 \geq k$ now follows from (4.44).
QED to Lemma 6

Effective bounds for the divisor function $d(n) = \sigma_0(n)$ are $d(n) \leq C_\epsilon n^\epsilon$, for any $\epsilon > 0$, where

$$C_\epsilon = \prod_{p < 2^{1/\epsilon}} \frac{1}{\epsilon\, \ln(p)\, e^{1-\epsilon \ln(p)}}\,, \tag{4.46}$$

where the product runs over all primes $p < 2^{1/\epsilon}$. To see this, recall $d(n) = \prod_p (a_p + 1)$ when $n = \prod_p p^{a_p}$ is the prime decomposition, so $d(n)/n^\epsilon = \prod_p \frac{a_p+1}{p^{\epsilon a_p}}$. The primes appearing in (4.46) are precisely those for which $\frac{a_p+1}{p^{\epsilon a_p}}$ can be > 1; the power a_p is then chosen to maximise this factor. Any $\epsilon < 1/2$ works for us, e.g. $C_{1/4} \approx 9.11...$ (in fact a slightly more refined analysis shows $C_{1/4}$ can be taken to be 8.55). Also, from $\ln y \leq y - 1$ we obtain $\ln(k) < 12\, k^{1/12} - 12$. Therefore we obtain as a bound on (4.35):

$$\left|\sum_{S_-/\delta \leq S \leq S_+/\delta} e\left(\frac{uS'}{R}\right)\varphi(r,\delta S)\right|$$
$$\leq (103\left|\frac{rh}{\delta}\right|^{5/6} - 74.8\left|\frac{rh}{\delta}\right|^{3/4})(.0084\frac{n^5h^6}{r^2}\sqrt{|D|} + .000377\frac{n^8h^9}{|r|^3}\delta|D| + .0164\frac{n^4h^6}{\delta|r|^3}\sqrt{|D|} + \frac{.091n^3h^3}{r^2})$$
$$< (1.065\frac{n^5h^{41/6}}{\delta^{5/6}|r|^{7/6}} - .733\frac{n^5h^{27/4}}{\delta^{3/4}|r|^{5/4}})\sqrt{|D|} + (.0389\frac{n^8h^{59/6}\delta^{1/6}}{|r|^{13/6}} - .028\frac{n^8h^{39/4}\delta^{1/4}}{|r|^{9/4}})|D|\,. \tag{4.47}$$

We can now bound the limit of (4.34) as $X \to \infty$, using the inequalities $n^{1-\mu}/(\mu-1) < \sum_{r=n}^{\infty} r^{-\mu} < n^{-\mu} + n^{1-\mu}/(\mu-1)$ for $\mu > 1$ which follow by comparing series with integral:

$$\lim_{X\to\infty}\left|\sum_{>}\right| \leq (19.136n^{29/6}h^{41/6} - 9.67n^{19/4}h^{27/4})\sqrt{|D|} + (.455n^{41/6}h^{59/6} - .359n^{27/4}h^{39/4})|D|\,. \tag{4.48}$$

When $n = 2$ (so $h = \delta = 1$), we get instead the weaker $\lim_{X\to\infty} |\sum_{>}| < 2136\sqrt{|D|} + 61|D|$.

Bounding $\sum_{<}$ is completely analogous; (4.27) becomes

$$\frac{m}{2nc} \equiv_1 \frac{ur'}{S} - \frac{\alpha r + \beta s}{2ns\,(\alpha r^2 + \beta rs + \gamma n' s^2)}\,, \tag{4.49}$$

where $\delta = \gcd(r, h) \in \{1, 3\}$, $S = ns/\delta$, r' is the inverse of r/δ mod S, and u is defined mod S by $u \equiv_S \delta^{-1}\,(1 + n's^2 - n'^2 s^4)$. The other equations and bounds are obtained by interchanging $r \leftrightarrow s$ and $\alpha \leftrightarrow n'\gamma$. In (4.34) and elsewhere it suffices to take $\delta \in \{1, 3\}$. Then (4.37),(4.38) become

$$|\varphi(r, s) - \varphi(r + \delta, s)| \le .056\frac{n^2h^6\delta}{|s|^3}\sqrt{|D|} + .0093\frac{n^3h^9\delta^2}{s^4}|D| + .34\frac{nh^6}{s^4}\sqrt{|D|}\,, \tag{4.50}$$

$$|\varphi(\delta\lfloor S_+/\delta\rfloor, s)| \le nh^3s^{-2}/3\,. \tag{4.51}$$

Therefore (4.35) becomes

$$\left|\sum_{S_-/\delta\le R\le S_+/\delta} e\left(\frac{uR'}{S}\right)\varphi(\delta R, s)\right| < (1.916\frac{n^{29/6}\delta^{1/6}}{|s|^{13/6}} - 1.26\frac{n^{19/4}\delta^{1/4}}{|s|^{9/4}})h^9|D|$$
$$+ (12.98\frac{n^{23/6}h^6}{\delta^{5/6}|s|^{7/6}} + 70.1\frac{n^{17/6}h^6}{\delta^{11/6}|s|^{13/6}} - 8.56\frac{n^{15/4}h^6}{\delta^{3/4}|s|^{5/4}} - 46\frac{n^{11/4}h^6}{\delta^{7/4}|s|^{9/4}})\sqrt{|D|}\,,$$

and we obtain

$$\lim_{X\to\infty}\left|\sum_{<}\right| \le (7.832n^{29/6}h^9 - 2.33n^{19/4}h^9)|D| + (201n^{23/6}h^6 - 72n^{15/4}h^6)\sqrt{|D|}\,.$$

All that remains is the sum over the representatives $[n\alpha, \beta, \gamma/h]$ of $\Gamma_0(n; h)$-equivalence classes of quadratic forms of discriminant D. Let $h'_{n;h}(D)$ denote the number of those (not necessarily primitive) equivalence classes. Note that our sum is now independent of α, β, γ, so a bound for $|Z_{n/2;h}(3/4)|$ will be the sum of our bounds for $\sum_{>}$ and $\sum_{<}$, multiplied by $h'_{n;h}(D)/2$ (the 2 here compensates for the overcounting, as mentioned earlier). Now, since all stabilisers here are $\pm I$, $h'_{n;h}(D)$ will equal the number of $\Gamma_0(n')$-equivalence classes of forms $[n'\alpha, \beta, \gamma]$, times the index of $\Gamma_0(n; h)$ in $\Gamma_0(n|h)$, and so we obtain the (crude) bound

$$h'_{n;h}(D) \le h'(D)\left|\frac{\mathrm{SL}_2(\mathbb{Z})}{\Gamma(n, h)}\right| \tag{4.52}$$

where $h'(D)$ is the total number of $\mathrm{SL}_2(\mathbb{Z})$-equivalence classes of integral forms (not necessarily primitive) of discriminant D, and where $\Gamma(n, h)$ consists of all matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ where n divides c and h divides b (this clearly forms a group). In deriving (4.52), we are conjugating everything by $\left(\begin{smallmatrix} h & 0 \\ 0 & 1 \end{smallmatrix}\right)$; $\Gamma(n, h)$ arises as the conjugate of the subgroup $\Gamma_0(nh)$ of $\Gamma_0(n;h)$. Now, the index of $\Gamma(n,h)$ in $\mathrm{SL}_2(\mathbb{Z})$ equals that of its conjugate $\Gamma_0(nh)$, since indices of Fuchsian groups can be expressed as a ratio of areas of fundamental domains and conjugating by $\mathrm{SL}_2(\mathbb{R})$ preserves those areas. Let $h(D)$ denote the class number of D, i.e. the number of $\mathrm{SL}_2(\mathbb{Z})$-equivalence classes of *primitive* integral quadratic forms of discriminant D. Then we have the bound

$$h(D) < \frac{\sqrt{|D|}}{\pi}\,(2+\log|D|) \tag{4.53}$$

(see Theorems 12.14.3 and 12.10.1 in [38]). Hence

$$\begin{aligned}\frac{h'(D)}{2} = \frac{1}{2}\sum_{m^2|D} h(D/m^2) &< \frac{\sqrt{|D|}}{2\pi}\sum_{m^2|D}\frac{2-\log m}{m} + \sqrt{|D|}\frac{\log|D|}{4\pi}\sum_{m^2|D} 1\\ &< 0.32\sqrt{|D|} + .681|D|^{5/8}\log|D|\,, \end{aligned}\tag{4.54}$$

using our earlier bound for the divisor function $d(n)$. Putting this all together, we obtain

$$h'_{n;h}(D)/2 < (0.32\sqrt{|D|} + .681|D|^{5/8}\log|D|)nh\prod_{p|(nh)}\frac{p+1}{p}\,, \tag{4.55}$$

and hence the bound given in the statement of our theorem. **QED to Theorem 3**

We can approximate the $2.13|D|^{1/8}\log|D|$ with the upper bound $120(|D|^{1/7}-|D|^{1/8})$ by the usual reasoning. Putting this all together, we obtain the following (very crude) bounds for the character values for each $g\in M_{24}$ and $k\geq 150$:

$$H_k(1) > \frac{4}{K}e^{\pi K/2} - \frac{4\pi}{\sqrt{2}}e^{\pi K/4} - 2.5\times 10^4 K^{23/7}\,, \tag{4.56}$$

$$|H_k(g)| < \frac{4}{K\sqrt{n_g}}e^{\pi K/(2n_g)} + \sqrt{8}\pi\, e^{\pi K/(4n_g)} + a_g\times 10^{b_g}K^{23/7}\,, \tag{4.57}$$

where $n_g=|g|$ is the order of g, $K=\sqrt{8k-1}$, and the values a_g, b_g are computed from Theorem 3 and are collected in Table 2. We find that when $k\geq 390$, the ratio $(H_k(1)/|M_{24}|)/(|H_k(g)|/|C_{M24}(g)|)$ exceeds 1.6×10^5 for all elements $g\neq 1$ except for g in conjugacy class 12B, where the ratio is >1.3. In particular we find that

$$\frac{H_k(1)}{|M_{24}|} > \sum_{g\neq 1}\frac{|H_k(g)|}{|C_{M24}(g)|}\,, \tag{4.58}$$

for all $k\geq 390$, where the sum is over all conjugacy classes in M_{24}. As explained in (4.1), this is sufficient to deduce positivity of the multiplicities of all M_{24}-irreps in these class functions H_k. Again, positivity (or rather nonnegativity) has been obtained experimentally for n up to 500, far more than we need.

It is somewhat disappointing that we need to check by hand (or rather, by computer!) positivity for so many k, when empirically (4.58) is satisfied for $k>30$. The cause of this are the bounds of Theorem 3, which apparently are far looser than they could be. But the value gained in tightening these bounds is far less than the effort to be spent, since it is so easy to calculate these character multiplicities. The reader interested in reducing 390 should focus on improving the bound for the case 12B (i.e. fix $n = 24, h = 12$ from the start, and restrict to $k > 100$ say; the index of $\Gamma_0(nh)$ in $\Gamma_0(n; h)$ here is 12, so the Theorem 3 bound can be improved immediately by that factor 12).

The bounds (4.56),(4.57) imply:

Theorem 4. *Choose any M_{24}-irrep ρ. Then the multiplicity $mult_\rho(H_n)$ of ρ in H_n tends to ∞ as $n \to \infty$. Moreover, $mult_\rho(H_n) > 0$ for all $n \geq 25$.*

Indeed, in this section we proved positivity of the multiplicities for $n \geq 390$; the values $25 \leq n < 390$ can be checked explicitly. An immediate corollary of Theorem 4 is the validity of Conjecture 5.11 in Umbral Moonshine [7]. However it should be remarked that the proof of this in [12] actually established a much stronger statement. Oddness of McKay-Thompson coefficients is far less trivial than strict positivity of certain multiplicities, since as we see almost every multiplicity will be strictly positive.

5 Is the Conway group the stringy symmetry?

In beautiful work, [30] followed Kondo's treatment [39] of Mukai's classification [42] of symplectic automorphisms of K3 surfaces, to obtain the symmetries of K3 sigma models. (Similar considerations are considered in [50].) It turns out all these stringy symmetries are subgroups of the Conway groups Co_0 or Co_1 (but not M_{24}), where they will necessarily generate the full group Co_0 (resp. Co_1). This begs the (perhaps naive) question: should the automorphism group of Mathieu Moonshine actually be a Conway group?

The Conway group Co_0 is the automorphism group of the Leech lattice; the simple group Co_1 is its quotient by its centre ± 1. Hence the Co_1-irreps are a subset of those of Co_0, consisting of those Co_0-irreps whose kernel contains -1. We call a Co_0-irrep a *spinor* if it is not trivial on -1. M_{24} is a subgroup of both Co_0 and Co_1. In this section we give the restrictions of Co_0 (hence Co_1) irreps to M_{24}, for irreps with dimension up to 1 million (there are 32 of these). The notation comes from the Atlas of Finite Groups [8]; in a couple places it differs slightly from that of [24] (e.g. the dimension-1035 irreps are in a different order: the conjugate ones we write as $1035'$ and $1035''$). The first step was identifying the conjugacy classes; once these are known, the character multiplicities follow directly from the chararacter table of M_{24} together with the orthogonality relations. The arguments are straightforward and we'll avoid the details, giving only the results.

Table 5. Matching of conjugacy classes

We find that any *virtual character* $\rho = m_0 + m_1\rho_1 + \cdots + m_{20}\rho_{20}$ of M_{24}, i.e. any linear combination with integer coefficients m_i of M_{24} irreps, is the restriction of a virtual Co_0-representation involving the first 32 irreps of Co_0, iff the multiplicities obey $m_2 = m_{\overline{2}}$, $m_3 = m_{\overline{3}}$, $m_8 = m_{\overline{8}}$, $m_{10} = m_{\overline{10}}$, as well as the relation $m_9 + m_{14} \equiv_2 m_{15}$. Thus it is hard for an M_{24}-representation to be a restriction of a virtual Co_0-representation (0% will be). Although the restriction map is not surjective, Theorem B tells us the Mathieu-Moonshine characters H_n lie in the image of that restriction. This is the content of Theorem C given earlier. In particular we have:

$$\begin{aligned}
&\rho_1 = \widetilde{\sigma}_1 - 1\,,\\
&\rho_2 + \overline{\rho_2} = 37\sigma_{14} + 39\sigma_{13} + 28\widetilde{\sigma}_{10} + \sigma_{12} + 12\sigma_{11} + 23\widetilde{\sigma}_8 + \sigma_{10} + 25\sigma_9 + 2\sigma_5 + 194\widetilde{\sigma}_4 + 24\widetilde{\sigma}_3 + 18\sigma_3\\
&\qquad +269\widetilde{\sigma}_1 - 28\sigma_{18} - 11\widetilde{\sigma}_{12} - 42\widetilde{\sigma}_9 - 44\widetilde{\sigma}_6 - 9\sigma_8 - 100\widetilde{\sigma}_5 - 18\sigma_7 - 78\sigma_6 - 144\sigma_2 - 218\sigma_1 - 155\,,\\
&\rho_3 + \overline{\rho_3} = 14\sigma_{13} + 11\widetilde{\sigma}_{10} + 15\sigma_{12} + 4\sigma_{11} + 6\widetilde{\sigma}_8 + 15\sigma_{10} + 8\sigma_9 + 105\widetilde{\sigma}_4 + 14\widetilde{\sigma}_3 + 64\sigma_3 + 121\widetilde{\sigma}_1\\
&\qquad -10\sigma_{18} - 4\widetilde{\sigma}_{12} - 15\widetilde{\sigma}_9 - 15\widetilde{\sigma}_6 - 20\sigma_8 - 12\widetilde{\sigma}_5 - 20\sigma_7 - 13\sigma_6 - 97\sigma_2 - 49\sigma_1 - 27\,,\\
&\rho_4 = \sigma_2 + 1 - 2\widetilde{\sigma}_1\,,\\
&\rho_5 = \sigma_1 + 1 - \widetilde{\sigma}_1\,,\\
&\rho_6 = 8\sigma_{14} + 14\sigma_{13} + 11\widetilde{\sigma}_{10} + 7\sigma_{12} + 4\sigma_{11} + 6\widetilde{\sigma}_8 + 7\sigma_{10} + 8\sigma_9 + 89\widetilde{\sigma}_4 + 14\widetilde{\sigma}_3 + 32\sigma_3 + 121\widetilde{\sigma}_1\\
&\qquad -10\sigma_{18} - 4\widetilde{\sigma}_{12} - 15\widetilde{\sigma}_9 - 15\widetilde{\sigma}_6 - 12\sigma_8 - 28\widetilde{\sigma}_5 - 12\sigma_7 - 21\sigma_6 - 81\sigma_2 - 73\sigma_1 - 51\,,\\

\end{aligned}$$

Of course we'd prefer true representations to virtual ones, but perhaps we should not be too surprised that virtual representations arise here, because the definition (2.1) of elliptic genus involves signs, and after all even H_{00} and H_0 were virtual (but see Section 6).

However, the dimensions of the virtual Co$_0$-representations needed will be *extremely* large. By the *total dimension* of a virtual representation $\rho_+ \ominus \rho_-$ we mean the quantity $\dim(\rho_+)+\dim(\rho_-)$. For any M_{24} representation, if there is any Co$_0$-virtual representation which restricts to it, there will be infinitely many (just add to it any of the above relations). For each basic combination of M_{24}-irreps, we have selected above the Co$_0$-virtual representation of smallest total dimension we could find, which restricts to it. (This ambiguity would be eliminated by identifying if possible the twining elliptic genera ϕ_g for all $g \in \mathrm{Co}_0$.)

For example, of all Co$_0$-irreps of dimension less than 1 million, only 2 of them contain ρ_2 or $\overline{\rho_2}$ as a summand: namely, a Co$_1$-irrep of dim 313950, and a spinor irrep of dim 789360. The smallest virtual Co$_0$-representation we could find which restricts to $\rho_2 + \overline{\rho_2}$ (a 90-dimensional representation of M_{24}) has total dimension over 100 billion.

In fact more is true. Suppose for contradiction the natural identification of the Witten index w_g with $\widetilde{\sigma}_1$ (the only Co_0-rep which restricts to $1 + \rho_1$). Now, [30] compute (among other things) the twining characters for the automorphism of the Gepner model $(1)^6$; they found two symmetries of order 9 (the bottom two rows of their Table 1), both of whose Witten indices equal 3, and whose twining elliptic genera are nonetheless different. However, Co_0 has only one conjugacy class (namely class 9C) of order 9 with $\widetilde{\sigma}_1 = 3$, and this would imply those twining genera should be equal. (We thank Roberto Volpato for sharing this observation.) This contradiction means that w_g cannot equal $\widetilde{\sigma}_1(g)$, and so the Witten genus too will be virtual, having total dimension much greater than 24. These large total dimensions make the proposed extension to the Conway groups seem unlikely.

6 Speculations

Because the phenomena underlying Mathieu Moonshine are still obscure, we conclude with assorted questions and speculations. The most obvious challenge suggested by this paper is to explicitly construct these representations H_n. The evidence that there is some vertex algebra-like object underlying the Mathieu Moonshine observations now seems overwhelming; perhaps the most satisfying way to construct the H_n would be to construct this vertex (super)algebra. This would provide the algebraic underpinning of Mathieu Moonshine, and it should hint at its still-mysterious geometric and physical meanings.

We regard this vertex superalgebra construction as the most important challenge of Mathieu Moonshine. At $c = 24$ we have an $N = 0$ VOA (namely the Moonshine Module $V^\natural$) with lots of nice properties including an action of $\mathbb{M}$. At $c = 12$ we have an $N = 1$ VOSA (namely Duncan's algebra [16]), with lots of nice properties including an action of the Conway group. Could there be at $c = 6$ an $N = 2$ or $N = 4$ VOSA (namely the algebra underlying our Mathieu Moonshine) with lots of nice properties including an action of M_{24}? After all, M_{24}, Co_1, $\mathbb{M}$ is the Holy Trinity of sporadic finite simple groups (e.g. Griess [35] constructed the Monster by starting with M_{24}, lifting to Conway and then moving on to the Monster). (I thank Gerald Höhn and Chongying Dong for informal discussions on this point).

Another possible construction, which may also bring K3 into Mathieu Moonshine, is through the chiral de Rham complex [40] (a sheaf of vertex superalgebras) associated to a K3 surface. The trace over its global section (which is itself a vertex superalgebra) recovers elliptic genus [3]. The orbifold theory, including the construction of twisted modules, has also been studied [26].

One of the most intriguing aspects of Mathieu Moonshine is the *positivity* of the irrep multiplicities. This discussion is already anticipated in Chapter 7.2 of Wendland's thesis [52]. There we find that the partition function in the Ramond-

Ramond sector of an $N = 4$ $c = 6$ superconformal field theory is

$$\begin{aligned} Z_{RR} =&|ch^s_{0,0}|^2 + h|ch^s_{1/4,0}|^2 + \epsilon\,(ch^s_{0,0}ch^{s*}_{1/4,0} + c.c.) + F ch^l_{1/4,1/2}ch^{s*}_{0,0} + F' ch^s_{0,0}ch^{l*}_{1/4,1/2} \\ &+ G ch^l_{1/4,1/2}ch^{s*}_{1/4,0} + G' ch^s_{1/4,0}ch^{l*}_{1/4,1/2} + H|ch^l_{1/4,1/2}|^2 \,, \end{aligned} \tag{6.1}$$

using the same conventions for $N = 4$ superconformal characters as (2.6), where h, ϵ are nonnegative integers and F, F', G, G', H are functions of τ, z with only nonnegative integer coefficients in $q, \overline{q}$. The elliptic genus is

$$\phi = (\epsilon - 2)ch^s_{0,0} + (h - 2\epsilon)ch^s_{1/4,0} + (G - 2F)ch^l_{1/4,1/2} \,. \tag{6.2}$$

For the K3 component of moduli space, $\epsilon = 0$ and $h = h^{1,1} = 20$. In particular note that the function F counts holomorphic fields which exist in that theory but which are not contained in the $N = 4$ vacuum representation. We can think of holomorphic fields, very roughly, as additional symmetries of the theory; since we would expect that generically the chiral algebra of the K3 sigma model is simply $N = 4$ superconformal, we should have generically $F = 0$. This would mean the non-BPS part of the elliptic genus is (generically) this function G which has only non-negative coefficients. From this the conjectured non-negativity would follow. This argument also applies to the character-valued elliptic genus, so all multiplicities should be nonnegative. A similar argument can be found in Ooguri [44]. (We thank Katrin Wendland for discussions on this point.)

It is commonly expected that the moduli space of $c = 6$ $N = 4$ superconformal field theories consists of two components: a toroidal one with vanishing elliptic genus, and the K3 sigma models with elliptic genus $2\phi_{0,1}$. But if this is true, then there can be no $c = 6$ $N = 4$ superconformal field theory underlying Mathieu moonshine: the work of [30] shows that the corresponding automorphism groups are too small.

But $N = 4$ (more precisely, $N = (4, 4)$) theories possess more supersymmetry than we need. We could deform an $N = (4, 4)$ theory to e.g. an $N = (0, 4)$ heterotic (see e.g. [55] for an introduction to similar theories). These theories are geometrical, corresponding to bundles over K3, and are also related to chiral de Rham. They possess the desired elliptic genus $2\phi_{0,1}$. The moduli space of these theories is 90-dimensional, far larger than that of $N = (4, 4)$, so there is a much greater chance for some larger symmetry groups. However, the breaking of the left-moving $N = 4$ supersymmetry seems to destroy the justification for decomposing the elliptic genus into $N = 4$ superconformal characters — a step crucial to Mathieu moonshine. It is tempting to partially break the supersymmetry, say to $N = (4, 1)$, but such theories seem to possess the full $N = (4, 4)$ supersymmetry. (I thank Ilarion Melnikov for discussions involving this point.)

The difficulty in interpreting Mathieu Moonshine in terms of K3 sigma models (e.g. the interesting work of Taormina-Wendland [50] is still far from realising M_{24}) leads one to consider the unhappy possibility that the connection with K3 is perhaps accidental. The relevant (twisted) elliptic genera are so heavily constrained that there are bound to be empty coincidences. For example, any of the 71 or so $c = 24$

holomorphic rational VOA — e.g. one associated to the Leech lattice — will have a VOA character (a.k.a. partition function) equal to $J(\tau)+c$ for some constant $c \in \mathbb{Z}_{\geq 0}$, again because it is so severely constrained. The coefficients of J (with or without c) will have an interpretation as dimensions of Monster representations as we know, but conjecturally only one of those VOAs actually carries a nontrivial action of the Monster $\mathbb{M}$. It takes a (slightly) deeper analysis to rule out Monster actions on these other VOAs. Could this relation of K3 sigma models to our Mathieu Moonshine be likewise illusory? After all, it is clear that the Jacobi forms of Umbral Moonshine cannot have a direct interpretation as elliptic genera, when the group is not M_{24}.

Similarly, perhaps we shouldn't regard M_{24} as sacrosanct. The evenness property of Theorem B hints perhaps that the symmetry is somewhat larger. The analysis of [30] and our Theorem C hints that the 'ultimate' symmetry lies somewhere between M_{24} and Conway. The split extension $\mathbb{Z}_2^{12} \rtimes M_{24}$, a maximal subgroup of Co_0, is the only such group and seems worth a look. (The evenness property was used in [12] to prove one of the Umbral Moonshine conjectures, and together with Theorem A proves that the elliptic genus of Enriques surfaces decomposes into a sum of M_{12} characters.)

The appearance of $\Gamma_0(|g|)$ in Lemma 1 is what one would expect from the CFT orbifold story. Let us quickly review that basic theory, as developed by [14],[15],[1], and others. Let $\mathcal{V}$ be a (bosonic) rational VOA with automorphisms containing some finite group G. By $\mathcal{V}^G$ we mean the vertex operator subalgebra consisting of all fixed-points of G in $\mathcal{V}$. Conjecturally, $\mathcal{V}^G$ is also rational; in the mathematical literature it is called the *orbifold* of $\mathcal{V}$ by G (the orbifold construction means something a little different in the physics literature).

We are interested here in the simplest case, where $\mathcal{V}$ only has a single irreducible module (namely itself). The twisted modules $M(g)$ of $\mathcal{V}$ are parametrised by (a subset of the) conjugacy class representatives g, and (a subgroup of) the centraliser of g in G acts on them, so we can define *twisted twining characters* $Z_{g,h}(\tau) = \mathrm{Tr}_{M_g}(hq^{L_0-c/24})$. The special case $Z_{1,h}(\tau)$ are sometimes called *McKay-Thompson series* in the mathematics literature. Then for any $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, $Z_{g,h}\left(\frac{a\tau+b}{c\tau+d}\right)$ will equal $Z_{g^a h^c, g^b h^d}(\tau)$ up to some phase. For general g, h, $Z_{g,h}(\tau)$ will thus be a modular function with multiplier for the group of all matrices $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma(\mathrm{lcm}(|g|,|h|))$. However, $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(|h|)$ will send the McKay-Thompson series $Z_{1,h}$ to another, Z_{1,h^d} (up to a phase). The integer d will be coprime to $|h|$, and sends a character value of h to a Galois associate. When the McKay-Thompson series have integer coefficients (e.g. in Monstrous or Mathieu Moonshine), these Galois associates have the same value, and $Z_{1,h^d} = Z_{1,h}$. In other words, since we have that integrality, our McKay-Thompson series $Z_{1,h}$ will be modular functions (with multiplier) for $\Gamma_0(|h|)$.

To complete the story, we need to consider equivariant cohomology. Let B_G be a classifying space, then the group cohomology $H^*_G(1;N)$ (often denoted $H^*(G;N)$) with values in a G-module N is defined by $H^*(B_G;N)$. Just as $H^2_G(1;U(1))$ controls the projective representatives of G, and $\alpha \in H^3_G(G;\mathbb{Z})$ (G acting on itself by conjugation) parametrises the possible orbifold fusion rings (all given by twisted equivariant K-theory ${}^{\alpha}K_G^0(G)$), the representation theory of $\mathcal{V}^G$ is controlled by a 3-cocycle $\alpha \in H_G^3(1;U(1))$. In particular, when α is trivial, the modules M of $\mathcal{V}^G$ conjecturally are in natural one-to-one correspondence with pairs (g,ψ), where g is a conjugacy class representative in G and ψ is an irrep of the centraliser $C_G(g)$. Their characters $\chi_M(\tau) = \mathrm{Tr}_M q^{L_0-c/24}$ form a vector-valued modular function for $\mathrm{SL}_2(\mathbb{Z})$ with multiplier explicitly defined in terms of G [14]. The twisted modules $M(g)$ of $\mathcal{V}$ are also (conjecturally) parametrised by all conjugacy class representatives g, and the full centraliser of g in G acts on them Then $Z_{g^k,h^k}(\tau) = Z_{g,h}(\tau)$ and $Z_{g,h}\left(\frac{a\tau+b}{c\tau+d}\right) = Z_{g^ah^c,g^bh^d}(\tau)$. When the cocycle is not trivial — the generic case — a subset of these pairs (g,ψ) and (g,h) will not be viable. Again, the characters of $\mathcal{V}^G$ should yield a vector-valued modular form, but the multiplier is more complicated (though known [11]). Similarly, the relations $Z_{g^k,h^k}(\tau) = Z_{g,h}(\tau)$ and $Z_{g,h}\left(\frac{a\tau+b}{c\tau+d}\right) = Z_{g^ah^c,g^bh^d}(\tau)$ have to be adjusted by phases determined by α.

We have order-12 phases in Mathieu Moonshine (e.g. the $e^{2\pi i cd/(|g|h)}$ in (2.17)), so we would expect (supposing the orbifold theory extends to our $N=4$ setting) the relevant 3-cocycle α to have order 12. Indeed, [18] computed that $H^3_{M24}(1;U(1)) \cong \mathbb{Z}_{12}$, and [31] explicitly verified that a generating cocycle yields the phases appearing in Mathieu Moonshine. Moreover, $H^3_{M23}(1;U(1)) \cong 1$ [41], and so the phases for elements lying in M_{23} should be trivial, and this indeed is what is observed. It is also observed that many pairs (g,h) are not viable, as expected since α is nontrivial. If some group G larger than M_{24} (e.g. Co_0 or $2^{12}.M_{24}$) actually acts here, then for this reason we'd require $H^3_G(1;U(1))$ to contain an order-24 element. (The cohomology of Co_0 has not been computed yet). It is observed in [31] that some twisted twining elliptic genera vanish even when there is no cohomological obstruction — this would be surprising for a bosonic theory but elliptic genera (being a signed trace) often vanishes in nontrivial theories so this is not mysterious here.

In summary, the perfect formal fit of twisted twining elliptic genera here with the general theory of VOA orbifolds, lends strong support to the belief that there is a vertex operator superalgebra underlying Mathieu Moonshine.

In the case of Monstrous Moonshine, the phases are 24th roots of 1, so we would expect the orbifold $(\mathcal{V}^\natural)^{\mathbb{M}}$ to be governed by an *order 24* cocycle. We would also expect this α to obstruct certain pairs $Z_{g,h}$. Indeed, empirical observations encapsulated in Norton's *Generalised Monstrous Moonshine* [43] make exactly this point: whether a pair is viable or not is captured by Norton's Fricke dichotomy. This should be equivalent to the cohomology condition. This relation between cohomology and Norton's mysterious Fricke condition seems to be new. It would be very interesting to make that relation more explicit.

Acknowledgements. It is my pleasure to thank Matthias Gaberdiel and, more generally, the conference participants of the Mathieu Moonshine workshop at ETH in July 2011, for discussions. I thank Thomas Creutzig, Matthias Gaberdiel, Gerald Höhn, Ilarion Melnikov, Roberto Volpato and Katrin Wendland for comments involving an earlier draft of this manuscript.

This is an informal write up of my talk at the I.C.M. in Berlin. It gives some background to Goddard's talk [Go] about the moonshine conjectures. For other survey talks about similar topics see [B94], [B98], [LZ], [J], [Ge], [Y].

The classification of finite simple groups shows that every finite simple group either fits into one of about 20 infinite families, or is one of 26 exceptions, called sporadic simple groups. The monster simple group is the largest of the sporadic finite simple groups, and was discovered by Fischer and Griess [G]. Its order is

$$\begin{aligned}&8080, 17424, 79451, 28758, 86459, 90496, 17107, 57005, 75436, 80000, 00000\\ =&2^{46}.3^{20}.5^{9}.7^{6}.11^{2}.13^{3}.17.19.23.29.31.41.47.59.71\end{aligned}$$

(which is roughly the number of elementary particles in the earth). The smallest irreducible representations have dimensions $1, 196883, 21296876, \ldots$. The elliptic modular function $j(\tau)$ has the power series expansion

$$j(\tau) = q^{-1} + 744 + 196884q + 21493760q^2 + \ldots$$

where $q = e^{2\pi i\tau}$, and is in some sense the simplest nonconstant function satisfying the functional equations $j(\tau) = j(\tau + 1) = j(-1/\tau)$. John McKay noticed some rather weird relations between coefficients of the elliptic modular function and the representations of the monster as follows:

$$\begin{aligned}1 &= 1\\ 196884 &= 196883 + 1\\ 21493760 &= 21296876 + 196883 + 1\end{aligned}$$

where the numbers on the left are coefficients of $j(\tau)$ and the numbers on the right are dimensions of irreducible representations of the monster. At the time he discovered these relations, several people thought it so unlikely that there could be a relation between the monster and the elliptic modular function that they politely told McKay that he was talking nonsense. The term “monstrous moonshine” (coined by Conway) refers to various extensions of McKay's observation, and in particular to relations between sporadic simple groups and modular functions.

For the benefit of readers who are not native English speakers, I had better point out that “moonshine” is not a poetic terms referring to light from the moon. It means

---

[*] Supported by a Royal Society professorship.

foolish or crazy ideas. (Quatsch in German.) A typical example of its use is the following quotation from E. Rutherford (the discoverer of the nucleus of the atom): "The energy produced by the breaking down of the atom is a very poor kind of thing. Anyone who expects a source of power from the transformations of these atoms is talking moonshine." (Moonshine is also a name for corn whiskey, especially if it has been smuggled or distilled illegally.)

We recall the definition of the elliptic modular function $j(\tau)$. The group $SL_2(\mathbf{Z})$ acts on the upper half plane H by

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}(\tau) = \frac{a\tau + b}{c\tau + d}.$$

A modular function (of level 1) is a function f on H such that $f((a\tau+b)/(c\tau+d)) = f(\tau)$ for all $\left(\begin{smallmatrix} ab \\ cd \end{smallmatrix}\right) \in SL_2(\mathbf{Z})$. It is sufficient to assume that f is invariant under the generators $\tau \mapsto \tau + 1$ and $\tau \mapsto -1/\tau$ of $SL_2(\mathbf{Z})$. The elliptic modular function j is the simplest nonconstant example, in the sense that any other modular function can be written as a function of j. It can be defined as follows:

$$\begin{aligned} j(\tau) &= \frac{E_4(\tau)^3}{\Delta(\tau)} \\ &= q^{-1} + 744 + 196884q + 21493760q^2 + \cdots \\ E_4(\tau) &= 1 + 240\sum_{n>0}\sigma_3(n)q^n \qquad\qquad (\sigma_3(n) = \sum_{d|n} d^3) \\ &= 1 + 240q + 2160q^2 + \cdots \\ \Delta(\tau) &= q\prod_{n>0}(1-q^n)^{24} \\ &= q - 24q + 252q^2 + \cdots \end{aligned}$$

A modular form of weight k is a holomorphic function $f(\tau) = \sum_{n\geq 0} c(n)q^n$ on the upper half plane satisfying the functional equation $f((a\tau+b)/(c\tau+d)) = (c\tau+d)^k f(\tau)$ for all $\left(\begin{smallmatrix} ab \\ cd \end{smallmatrix}\right) \in SL_2(\mathbf{Z})$. The function $E_4(\tau)$ is an Eisenstein series and is a modular form of weight 4, while $\Delta(\tau)$ is a modular form of weight 12.

The function $j(\tau)$ is an isomorphism from the quotient $SL_2(\mathbf{Z})\backslash H$ to $\mathbf{C}$, and is uniquely defined by this up to multiplication by a constant or addition of a constant. In particular any other modular function is a function of j, so j is in some sense the simplest nonconstant modular function.

An amusing property of j (which so far seems to have no relation with moonshine) is that $j(\tau)$ is an algebraic integer whenever τ is an imaginary quadratic irrational number. A well known consequence of this is that

$$\exp(\pi\sqrt{163}) = 262537412640768743.99999999999925\ldots$$

is very nearly an integer. The explanation of this is that $j((1+i\sqrt{163})/2)$ is exactly the integer $-262537412640768000 = -2^{18}3^3 5^3 23^3 29^3$, and

$$\begin{aligned} j((1+i\sqrt{163})/2) &= q^{-1} + 744 + 196884q + \cdots \\ &= -e^{\pi\sqrt{163}} + 744 + (\text{something very small}). \end{aligned}$$

McKay and Thompson suggested that there should be a graded representation $V = \oplus_{n\in\mathbf{Z}} V_n$ of the monster, such that $\dim(V_n) = c(n-1)$, where $j(\tau) - 744 = \sum_n c(n)q^n = q^{-1} + 196884q + \cdots$. Obviously this is a vacuous statement if interpreted literally, as we could for example just take each V_n to be a trivial representation. To characterize V, Thompson suggested looking at the McKay-Thompson series

$$T_g(\tau) = \sum_n Tr(g|V_n)q^{n-1}$$

for each element g of the monster. For example, $T_1(\tau)$ should be the elliptic modular function. Conway and Norton [C-N] calculated the first few terms of each McKay-Thomson series by making a reasonable guess for the decomposition of the first few V_n's into irreducible representations of the monster. They discovered the astonishing fact that all the McKay-Thomson series appeared to be Hauptmoduls for certain genus 0 subgroups of $SL_2(\mathbf{R})$. (A Hauptmodul for a subgroup Γ is an isomorphism from $\Gamma\backslash H$ to $\mathbf{C}$, normalized so that its Fourier series expansion starts off $q^{-1} + O(1)$.)

As an example of some Hauptmoduls of elements of the monster, we will look at the elements of order 2. There are 2 conjugacy classes of elements of order 2, usually called the elements of types $2A$ and $2B$. The corresponding McKay-Thompson series start off

$$T_{2B}(\tau) = q^{-1} + 276q - 2048q^2 + \cdots \qquad \text{Hauptmodul for } \Gamma_0(2)$$
$$T_{2A}(\tau) = q^{-1} + 4372q + 96256q^2 + \cdots \qquad \text{Hauptmodul for } \Gamma_0(2)+$$

The group $\Gamma_0(2)$ is $\{\binom{ab}{cd} \in SL_2(\mathbf{Z}) | c \text{ is even}\}$, and the group $\Gamma_0(2)+$ is the normalizer of $\Gamma_0(2)$ in $SL_2(\mathbf{R})$. Ogg had earlier commented on the fact that the full normalizer $\Gamma_0(p)+$ of $\Gamma_0(p)$ for p prime is a genus 0 group if and only if p is one of the primes 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 47, 59, or 71 dividing the order of the monster.

Conway and Norton's conjectures were soon proved by A. O. L. Atkin, P. Fong, and S. D. Smith. The point is that to prove something is a virtual character of a finite group it is only necessary to prove a finite number of congruences. In the case of the moonshine module V, proving the existence of an infinite dimensional representation of the monster whose McKay-Thompson series are given Hauptmoduls requires checking a finite number of congruences and positivity conditions for modular functions, which can be done by computer.

This does not give an explicit construction of V, or an explanation about why the conjectures are true. Frenkel, Lepowsky, and Meurman managed to find an explicit construction of a monster representation $V = \oplus V_n$, such that $\dim(V_n) = c(n-1)$, and this module had the advantage that it came with some extra algebraic structure preserved by the monster. However it was not obvious that V satisfied the Conway-Norton conjectures. So the main problem in moonshine was to show that the monster modules constructed by Frenkel, Lepowsky and Meurman on the one hand, and by Atkin, Fong, and Smith on the other hand, were in fact the same representation of the monster.

Peter Goddard [Go] has given a description of the proof of this in his talk in this volume, so I will only give a quick sketch of this. The main steps of the proof are as follows:

1. The module V constructed by Frenkel, Lepowsky, and Meurman has an algebraic structure making it into a "vertex algebra". A detailed proof of this is given in [F-L-M].
2. Use the vertex algebra structure on V and the Goddard-Thorn no-ghost theorem [G-T] from string theory to construct a Lie algebra acted on by the monster, called the monster Lie algebra.
3. The monster Lie algebra is a "generalized Kac-Moody algebra" ([K90]); use the (twisted) Weyl-Kac denominator formula to show that $T_g(\tau)$ is a "completely replicable function".
4. Y. Martin [M], C. Cummins, and T. Gannon [C-G] proved several theorems showing that completely replicable functions were modular functions of Hauptmoduls for genus 0 groups. By using these theorems it follows that T_g is a Hauptmodul for a genus 0 subgroup of $SL_2(\mathbf{Z})$, and hence V satisfies the moonshine conjectures. (The original proof used an earlier result by Koike [Ko] showing that the appropriate Hauptmoduls were completely replicable, together with a boring case by case check and the fact that a completely replicable function is characterized by its first few coefficients.)

We will now give a brief description of some of the terms above, starting with vertex algebras. The best reference for finding out more about vertex algebras is Kac's book [K]. In this paragraph we give a rather vague description. Suppose that V is a commutative ring acted on by a group G. We can form expressions like

$$u(x)v(y)w(z)$$

where $u, v, w \in V$ and $x, y, z \in G$, and the action of $x \in G$ on $u \in V$ is denoted rather confusingly by $u(x)$. (This is not a misprint for $x(u)$; the reason for this strange notation is to make the formulas compatible with those in quantum field theory, where u would be a quantum field and x a point of space-time.) For each fixed $u, v, \ldots \in V$, we can think of $u(x)v(y)\cdots$ as a function from G^n to V. We can rewrite the axioms for a commutative ring acted on by G in terms of these functions. We can now think of a vertex algebra roughly as follows: we are given lots of functions from G^n to V satisfying the axioms mentioned above, with the difference that these functions are allowed to have certain sorts of singularities. In other words a vertex algebra is a sort of commutative ring acted on by a group G, except that the multiplication is not defined everywhere but has singularities. In particular we cannot recover an underlying ring by defining the product of u and v to be $u(0)v(0)$, because the function $u(x)v(y)$ might happen to have a singularity at $u = v = 0$.

It is easy to write down examples of vertex algebras: any commutative ring acted on by a group G is an example. (Actually this is not quite correct: for technical reasons we should use a formal group G instead of a group G.) Conversely any vertex algebra "without singularities" can be constructed in this way. Unfortunately there are no easy examples of vertex algebras that are not really commutative rings. One reason for this is that nontrivial vertex algebras must be infinite dimensional; the point is that if a vertex algebra has a nontrivial singularity, then by differentiating it we can make the singularity worse and worse, so we must have an infinite dimensional space of singularities. This is only possible if the vertex algebra is infinite dimensional. However there are plenty of important infinite dimensional examples; see for example Kac's book for a construction of the most important examples, and [FLM] for a construction of the monster vertex algebra.

Next we give a brief description of generalized Kac-Moody algebras. The best way to think of these is as infinite dimensional Lie algebras which have most of the good properties of finite dimensional reductive Lie algebras. Consider a typical finite dimensional reductive Lie algebra G, (for example the Lie algebra $G = M_n(\mathbf{R})$ of $n \times n$ real matrices). This has the following properties:

1. G has an invariant symmetric bilinear form $(,)$ (for example $(a, b) = -Tr(a, b)$).
2. G has a (Cartan) involution ω (for example, $\omega(a) = -a^t$).
3. G is graded as $G = \oplus_{n\in\mathbf{Z}} G_n$ with G_n finite dimensional and with ω acting as -1 on the "Cartan subalgebra" G_0. (For example, we could put the basis element $e_{i,j}$ of $M_n(\mathbf{R})$ in G_{i-j}.)
4. $(a, \omega(a)) > 0$ if $g \in G_n$, $g \neq 0$.

Conversely any Lie algebra satisfying the conditions above is essentially a sum of finite dimensional and affine Lie algebras. Generalized Kac-Moody algebras are defined by the same conditions with one small change: we replace condition 4 by

4'. $(a, \omega(a)) > 0$ if $g \in G_n$, $g \neq 0$ and $n \neq 0$.

This has the effect of allowing an enormous number of new examples, such as all Kac-Moody algebras and the Heisenberg Lie algebra (which behaves like a sort of degenerate affine Lie algebra). Generalized Kac-Moody algebras have many of the properties of finite dimensional semisimple Lie algebras, and in particular they have an analogue of the Weyl character formula for some of their representations, and an analogue of the Weyl denominator formula. An example of the Weyl-Kac denominator formula for the algebra $G = SL_2[z, z^{-1}]$ is

$$\prod_{n>0}(1 - q^{2n})(1 - q^{2n-1}z)(1 - q^{2n-1}z^{-1}) = \sum_{n\in\mathbf{Z}}(-1)^n q^{n^2} z^n.$$

This is the Jacobi triple product identity, and is also the Macdonald identity for the affine Lie root system corresponding to A_1.

Dyson described Macdonald's discovery of the Macdonald identities in [D]. Dyson found identities for $\eta(\tau)^m = q^{m/24}\prod_{n>0}(1 - q^n)^m$ for the following values of m:

$$3, 8, 10, 14, 15, 21, 24, 26, 28, \ldots$$

and wondered where this strange sequence of numbers came from. (The case $m = 3$ is just the Jacobi triple product identity with $z = 1$.) Macdonald found his identities corresponding to affine root systems, which gave an explanation for the sequence above: with one exception, the numbers are the dimensions of simple finite dimensional complex Lie algebras. The exception is the number 26 (found by Atkin), which as far as I know has not been explained in terms of Lie algebras. It seems possible that it is somehow related to the fake monster Lie algebra and the special dimension 26 in string theory.

Next we give a quick explanation of "completely replicable" functions. A function is called completely replicable if its coefficients satisfy certain relations. As an example of a completely replicable function, we will look at the elliptic modular function $j(\tau) - 744 = \sum c(n)q^n$. This satisfies the identity

$$j(\sigma) - j(\tau) = p^{-1}\prod_{\substack{m>0\\ n\in\mathbf{Z}}}(1 - p^m q^n)^{c(mn)}$$

where $p = e^{2\pi i\sigma}$, $q = e^{2\pi i\tau}$. (This formula was proved independently in the 80's by Koike, Norton, and Zagier, none of whom seem to have published their proofs.) Comparing coefficients of $p^m q^n$ on both sides gives many relations between the coefficients of j whenever we have a solution of $m_1 n_1 = m_2 n_2$ in positive integers, which are more or less the relations needed to show that j is completely replicable. For example, from the relation $2 \times 2 = 1 \times 4$ we get the relation

$$c(4) = c(3) + \frac{c(1)^2 - c(1)}{2}$$

or equivalently

$$20245856256 = 864299970 + \frac{196884^2 - 196884}{2}.$$

In the rest of this paper we will discuss various extensions of the original moonshine conjectures, some of which are still unproved. The first are Norton's "generalized moonshine" conjectures [N]. If we look at the Hauptmodul $T_{2A}(\tau) = q^{-1} + 4372q + \ldots$ we notice that one of the coefficients is almost the same as the dimension 4371 of the smallest nontrivial irreducible representation of the baby monster simple group, and the centralizer of an element of type 2A in the monster is a double cover of the baby monster. Similar things happen for other elements of the monster, suggesting that for each element g of the monster there should be some sort of graded moonshine module $V_g = \oplus_n V_{g,n}$ acted on by a central extension of the centralizer $Z_M(g)$. In particular we would get series $T_{g,h}(\tau) = \sum_n Tr(h|V_{g,n})q^n$ satisfying certain conditions. Some progress has been made on this by Dong, Li, and Mason [D-L-M], who proved the generalized moonshine conjectures in the case when g and h generate a cyclic group by reducing to the case when $g = 1$ (the ordinary moonshine conjectures). G. Höhn [H] has made some progress in the harder case when g and h do not generate a cyclic group by constructing the required modules for the baby monster (when g is of type $2A$). It seems likely that his methods would also work for the Fischer group Fi_{24}, but it is not clear how to go further than this. There might be some relation to elliptic cohomology (see [Hi] for more discussion of this), as this also involves pairs of commuting elements in a finite group and modular forms.

The space V_g mentioned above does not always have an invariant vertex algebra structure on it. Ryba discovered that a vertex algebra structure sometimes magically reappears when we reduce V_g modulo the prime p equal to the order of g. In fact V_g/pV_g can often be described as the Tate cohomology group $\hat{H}^0(g, V)$ for a suitable integral form V of the monster vertex algebra. This gives natural examples of vertex algebras over finite fields which do not lift naturally to characteristic 0. (Note that most books and papers on vertex algebras make the assumption that we work over a field of characteristic 0; this assumption is often unnecessary and excludes many interesting examples such as the one above.)

We will finish by describing some more of McKay's observations about the monster, which so far are completely unexplained. The monster has 9 conjugacy classes of elements that can be written as the product of two involutions of type $2A$, and their orders are 1, 2, 3, 4, 5, 6, 2, 3, 4. McKay pointed out that these are exactly the numbers appearing on an affine E_8 Dynkin diagram giving the linear relation between the simple roots. They are also the degrees of the irreducible representations of the binary icosahedral group. A similar thing happens for the baby monster: this time there are 5 classes of elements that are the product of two involutions of type $2A$ and their orders are 2, 4, 3, 2, 1. (This is connected with the fact that the baby monster is a "3,4-transposition group".) These are the numbers on an affine F_4 Dynkin diagram, and if we take the "double cover" of an F_4 Dynkin diagram we get an E_7 Dynkin diagram. The number on an E_7 Dynkin diagram are 1, 1, 2, 2, 3, 3, 4, 2 which are the dimensions of the irreducible representations of the binary octahedral group. The double cover of the baby monster is the centralizer of an element of order 2 in the monster. Finally a similar thing happens for $Fi_{24}.2$: this time there are 3 classes of elements that are the product of two involutions of type $2A$ and their orders are 2, 3, 1. (This is connected with the fact that $F_{24}.2$ is a "3-transposition group".) These are the numbers on an affine G_2 Dynkin diagram, and if we take the "triple cover" of an G_2 Dynkin diagram we get an E_6 Dynkin diagram. The number on an E_6 Dynkin diagram are 1, 1, 1, 2, 2, 2, 3, which are the dimensions of the irreducible representations of the binary tetrahedral group. The triple cover of $Fi_{24}.2$ is the centralizer of an element of order 3 in the monster.

The connection between Dynkin diagrams and 3-dimensional rotation groups is well understood (and is called the McKay correspondence), but there is no known explanation for the connection with the monster.

Modular Forms and Moonshine
A Brief introduction

By David Padvorac

Abstract

Modular forms arise in primarily in algebra and number theory; as is well known, algebra and number theory are intricately interwoven. It is well known that algebra and number theory arise often in the natural world; likewise for modular forms, whose base is in both algebra and number theory. Elliptic curves arise in both algebra and number theory, and are tightly connected with modular forms. My goal will be to develop most of the necessary content related to modular forms to sketch the motivating observation behind the Monstrous Moonshine conjecture. The actual conjecture involves module theory and representation theory, which are both rather out of the scope of this project.

Introduction

As noted in the abstract, the end motivation here, in simple, is to develop the definitions needed to actually understand the very peculiar key observation that brought about “moonshine” theory, a recent development interweaving number theory, algebra, and to a lesser extent, physics. By taking this admittedly very shallow approach to introducing modular forms, it is sure that a large portion of their depth will be lost; as an undergraduate research project, this is nearly bound to happen regardless, as many needed ideas are in the toolboxes of graduate algebra. That is the downside of what I’ll be presenting here. The upshot is that it will be an undergraduate-accessible introduction to these topics, and a small glimpse into the motivation of the Monstrous Moonshine theory and conjectures.

Lattices

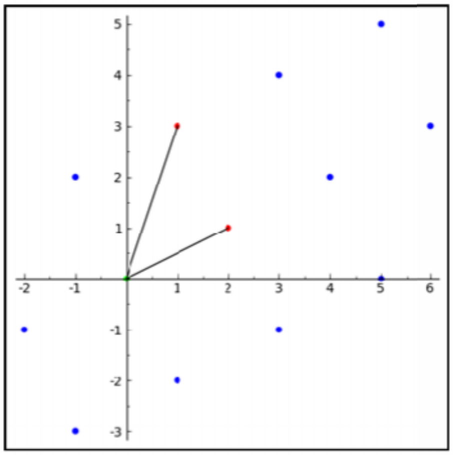
The lattice is a tremendously important tool; for starters, modular forms can be viewed as analytic functions on lattices in the complex plane. This will give us a simple definition to begin looking at modular forms with. A lattice λ in the complex plane is completely defined by two points in the plane with a non-real ratio:

$$\omega_1, \omega_2, \tau \in C; \frac{\omega_1}{\omega_2} = \tau \in H$$

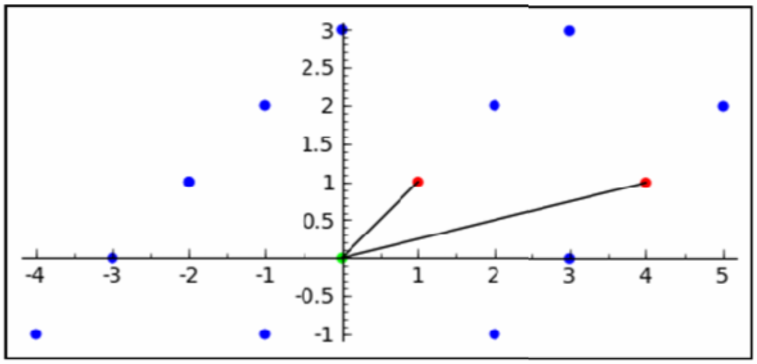
$$\lambda = L(\omega_1, \omega_2) = \{a\omega_1 + b\omega_2 : a, b \in Z\}$$

where H is the upper half plane, C is the complex plane, and in a shocking twist of events, we call the integers Z. This pair of points, the basis of the lattice, can be thought of as a pair of vectors in R^2. If the ratio of the two points is real, than equivalently the pair of vectors in R^2 is collinear, and will generate a boring lattice. Below are several examples of lattices, $L(1 + i, 4 + i)$ and $L(2 + i, 1 + 3i)$, plotted in Sage. The two generating points, ω_1 and ω_2 are red and the other lattice points are blue.

$L(2 + i, 1 + 3i)$



$L(1 + i, 4 + i)$



It is worth noting that if one of the basis points is in the lower half plane, it can be “shifted” to the upper half plane by an addition of an integer multiple of the other basis point, and doing this yields a basis that generates the same lattice. For simplicity’s sake, we’ll only use bases with both points in the upper half plane. Additionally, the lattice base does not have to be integer; integer bases were chosen for ease of visualization/calculation.

A function $G: \lambda \to C$ is simply a complex function restricted to the given set of lattice points; for example, taking the trivial lattice of Gaussian integers, $\lambda = L(1, i)$, $G(\lambda)$ is simply the range of G when evaluated at integer points in C. An important concept is the homogeneous function:

$G: \lambda \to C$ is homogeneous of degree –k, if:

$$G(a\lambda) = a^{-k}G(\lambda);\ \ k \in Z, a \in C$$

Examples:

1. $k = 0$: $G(a\lambda) = G(\lambda)$
2. $k = 1$: $G(a\lambda) = \frac{1}{a}G(\lambda)$
3. $k = 2$: $G(a\lambda) = \frac{1}{a^2}G(\lambda)$

It is worth noting that in these examples, that by intuition there seems to be a periodicity of some sort. Unfortunately a straight-up “normal” periodicity, as observed with sine or cosine, or any other similar function, only appears in a special case where $k = 0$; the other cases are this peculiar “scaling” sort of periodicity.

The set of homogenous functions of degree –k is in direct bijective correspondence with the set of modular forms of weight k; the proof is in Lang’s text, and will not be copied here. This simply gives an additional context for modular forms to be viewed in, which plays a key role later in the more detailed development of modular forms omitted in this paper.

The Modular Group

The modular group is a name for the group of invertible $n\ x\ n$ integer matrices, otherwise known as $SL_2(Z)$. Each element of the modular group is assigned to a function, a Linear Fractional Transformation, and operates on the upper half plane as follows:

$$\tau \in H\ ;\ \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \sigma \in SL_2(Z)$$
$$\sigma(\tau) = \frac{a\tau + b}{c\tau + d}$$

The proof that $\tau \in H \Rightarrow \sigma(\tau) \in H$, i.e. that the modular group maps the upper half plane to itself, is an elementary calculation; the only significant step is the clearing of complex numbers from the denominator of $\sigma(\tau)$, and this is done by multiplying the numerator and denominator by the complex conjugate of the denominator. The modular group is generated by two elements, $\sigma_1$andσ_2:

$$\sigma_1 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix};\ \sigma_1(\tau) = \tau + 1$$
$$\sigma_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix};\ \sigma_2(\tau) = -\frac{1}{\tau}$$

The proof of this fact is a somewhat involved calculation but does not provide much deep insight, and so is omitted.

Some Complex Analysis Terminology

- A complex function is holomorphic if it is complex-differentiable (similar to differentiability of a function from R^2 to R^2) on some neighborhood of every point in its domain.
- Meromorphicity is a very slightly generalized version of holomorphicity. A function with isolated poles, which is holomorphic everywhere except at those poles, is called "meromorphic."

A nice intuitive geometry way to think of a meromorphic function is as the top of an old style camping tent; generally speaking, it's a nice and smooth surface except for where the tent poles poke the material up. Those points aren't too nice, but they are well isolated.

Weak Modularity

A meromorphic function $f: H \to C$ is considered weakly modular of weight k if the following condition holds:

$$f(\sigma(\tau))(c\tau + d)^k = f(\tau), \sigma(\tau) = \frac{a\tau+b}{c\tau+d}$$

where σ is an element of the modular group and τ is an element of the upper half plane. Because the modular group is generated by the afore mentioned two elements σ_1 and σ_2, we can check if any function is weakly modular of some weight by checking these two inequalities, which come from plugging σ_1 and σ_2 into our definition:

1. $\sigma_1(\tau) = \tau + 1$: $\quad f(\tau) = f(\tau + 1)$
2. $\sigma_2(\tau) = -\frac{1}{\tau}$: $\quad f(\tau) = \tau^k f\left(-\frac{1}{\tau}\right)$

There are several important facts we can observe.

1. For all weights:
    a. $f(\tau)$ is Z-periodic, i.e. it repeats itself on a unit interval: $f(\tau) = f(\tau + n)$ for any integer n. This can be proven by a trivial application of induction to (1).

   b. The zeroes and poles of $f(\tau)$ are invariant under operation by $SL_2(Z)$ on τ. This follows by comparing the right and left hand sides of the definition above: clearly the factor $(c\tau + d)^k$ will not have zeroes or poles, so $f(\tau)$ has zeroes and/or poles if corresponding exactly to those of $f\big(\sigma(\tau)\big)$.

2. For weight $k = 0$, $f(\tau)$ is invariant under the modular group, $SL_2(Z)$. This follows from setting $k = 0$ in equation (2).
3. For any odd weight $f(\tau) \equiv 0$. We can see this by setting $\sigma = -I$ in the definition. This gives us $f(\tau)(-1) = f(\tau)$, clearly only true when $f(\tau) \equiv 0$.
4. For weight $k = 2$, we get a result familiar from path integrals of complex analysis. There is a bit of legwork to do to see this result, however.
   a. First we manipulate our definition to get that $\frac{f(\sigma(\tau))}{f(\tau)} = \frac{1}{(c\tau+d)^2}$
   b. Next, we note that $\frac{d\sigma}{d\tau} = \frac{1}{(c\tau+d)^2}$; this derivative can be calculated easily using the quotient rule and the definition of $\sigma(\tau)$.
   c. Finally, equating the right hand sides of the two equations and redistributing the fractions, we have $f\big(\sigma(\tau)\big)d\sigma(\tau) = f(\tau)d\tau$, and so a path integral in the complex plane is invariant under $SL_2(Z)$.

Modular Forms

A function $f: H \to C$ is called a modular form of weight k if the following conditions satisfied:

1. f is holomorphic on H
2. f is holomorphic “at infinity”
3. f is weakly modular of weight k

For a function $f(\tau)$ to be holomorphic “at infinity” simply means that it must be bounded as $Im(\tau) \to \infty$. An easy way to show this would be by showing that $\lim_{Im(\tau)\to\infty} f(\tau)$ exists and is finite. This condition is necessary for some further results on the set of all modular forms of some given weight; this set is denoted $M_k(SL_2(Z))$.

An important example of specific type of modular form is the cusp form of weight k, a modular form of weight k, with the addition that in its Fourier expansion, the first terms coefficient is zero.

$$f(\tau) = \sum_{n=1}^{\infty} a_n q^n, \quad q = e^{2\pi i\tau}$$

$f(\tau)$ a cusp form □ $a_n = 0$

Also, from this definition we also have that a modular form is a cusp form when $\lim_{Im(\tau)\to\infty} f(\tau) = 0$. The significance of cusp forms to this work will be in defining a very important modular form in terms of them; this function plays a key role in the question that motivated the moonshine conjectures.

Eisenstein Series

An Eisenstein series is essentially a 2-dimensional analog of the Riemann zeta function. In good tradition (and it also happens to be the generally accepted standard definition), we first use a definition that looks just like Riemann's original definition (this definition and it's immediate corollaries are directly from Diamond and Shurman).

$$G_k(\tau) = \sum_{(c,d) \in I} \frac{1}{(c\tau + d)^k} ;$$

$$\tau \in \mathcal{H}$$
$$k \in \mathbb{Z}$$
$$I = \mathbb{Z}^2 - \{(0,0)\}$$

G_k is absolutely convergent $\forall k$ and uniformly convergent on compact subsets of $\mathcal{H}$. By definition than, G_k is holomorphic on $\mathcal{H}$. By applying an arbitrary element σ of $SL_2(Z)$ to τ and using some tricky manipulation of the summation of $G_k(\sigma(\tau))$, it falls out that G_k is weakly modular with weight k. Lastly, G_k is bounded as $Im(\tau) \to \infty$, so it is indeed a modular form.

We now define two important cusp forms. They do seem entirely arbitrary, and neither their purpose nor significance readily meets the eye. This is understandable, considering that they are part of a much more complicated thing, the Weierstrass $\wp$-function: they are the 2nd and 3rd coefficients of its Laurent expansion. The $\wp$-function won't be discussed here, although it is part of Koblitz's presentation of elliptic curves, and can be studied in full depth in his text.

$$g_2(\tau) = 60G_4(\tau)$$
$$g_3(\tau) = 140G_6(\tau)$$

Now, we define the elliptic discriminant function $\Delta(\tau)$, and the modular invariant $j(\tau)$. Again, like with g_2 and g_3, a full development of the nature and contexts of these functions isn't included here. They both play key roles in the theory of elliptic curves and modular forms.

$$\Delta: \mathcal{H} \to \mathbb{C}$$
$$\Delta(\tau) = (g_2(\tau))^3 + 27(g_3(\tau))^2$$

$$j: \mathcal{H} \to \mathbb{C}$$
$$j(\tau) = 1728 \frac{(g_2(\tau))^3}{\Delta(\tau)}$$

There is a trivially-proved result on modular forms that the weight of the product of two forms is the product of their weights. From this, we can note that the numerator and denominator of $j(\tau)$ both have the same weight; it follows that $j(\tau)$ is invariant under $SL_2(Z)$. Finally, writing $j(\tau)$ as a Fourier series in terms of $q = e^{2\pi i\tau}$:

$$j(\tau) = q^{-1} + 744 + 196{,}884q + 21{,}493{,}760q^2 + 864{,}299{,}970q^3 + \cdots$$

Note: the four definitions given here are taken straight from the corresponding section of the text by Diamond and Shurman.

This is the end of the good definitions I'll give here. The rest of the needed content is either from entry level algebra or upper level algebra, or just simply very inaccessible in any rigor to most typical undergraduates, myself included. For the inaccessible content, I'll give the hand-waving definitions and descriptions.

Some Light Definitions

1. Finite Simple Groups
   Gannon very succinctly describes finite simple groups in his text; I'll summarize it here:
   "Finite simple groups are to finite groups what the primes are to integers—they are their elementary building blocks."

   All finite simple groups have been classified, this monumental work was wrapped up, give or take, in the late 90's. There are 18 infinite families (for example, cyclic groups of prime order, $\mathbb{Z}/p\mathbb{Z}$) and 26 exceptional groups. The largest of these groups is the so called "monster" group of Fischer and Griess. The order of the monster group is approximately 8×10^{53}.

2. Representation theory
   Again, we'll use Gannon's description:
   A representation of a group is an assignment of an $n \times n$ matrix $A(g)$ to each element of that group, so that the matrix product respects the group product:
   $$A(g_1)A(g_2) = A(g_1g_2)$$
   In essence, a representation of a group is a full description of its structure in the language of linear algebra. The dimension of a representation is the size n of the matrices.
   An representation can be reduced in terms of subspaces of the vector space V acted on by the matrices A. A subspace of V fixed under the group action matrices A is essentially a building block for the representation.

The Observation!

And finally, we've come to the point where we can look at the observation made by John McKay, detailed in Gannon's text. Mckay first noticed the following:

$$196{,}884 \approx 196{,}883$$
$$21{,}493{,}760 \approx 21{,}296{,}876$$
$$864{,}299{,}970 \approx 842{,}609{,}326$$

and shortly came to a more precise resulting numerology:

$$196{,}884 = 196{,}883 + 1$$
$$21{,}493{,}760 = 21{,}296{,}876 + 196{,}883 + 1$$
$$864{,}299{,}970 = 842{,}609{,}326 + 21{,}296{,}876 + 2 \times 196{,}883 + 2 \times 1$$

The numbers on the right side of these equalities are the first coefficients of the modular invariant, $j(\tau)$. The numbers on the right hand side are the dimensions of smallest "building blocks" of the group representation of the Monster group.

This striking set of equalities continues, for all coefficients of the modular invariant. The conjecture this observation lead to is, again, far beyond the means of this paper. Regardless, I do believe that this seemingly-out-of-nowhere correspondence is simply another example of the relations that appear in seemingly completely unrelated fields of mathematics. There are implications of this observation in physics, more specifically string theory; even rudimentary explanations of these implications are far beyond my current grasp.

The monster simple group acts on the monster vertex algebra, and the moonshine conjectures state that the traces of elements of the monster on the vertex algebra are Hauptmoduls. Ryba [R94] conjectured the existence of similar vertex algebras over fields of characteristics p acted on by the centralizers of certain elements of prime order p in the monster, and conjectured that the Brauer traces of p-regular elements of the centralizers were certain Hauptmoduls. We will prove these conjectures when the centralizer involves a sporadic group ($p \leq 11$, corresponding to the sporadic groups B, Fi'_{24}, Th, HN, He, and M_{12}).

1. Introduction.

The original "moonshine conjectures" of Conway, Norton, McKay, and Thompson said that the monster simple group M has an infinite dimensional graded representation $V = \oplus_{n\in\mathbf{Z}} V_n$ such that the dimension of V_n is the coefficient of q^n of the elliptic modular function $j(\tau)-744 = q^{-1}+196884q+\cdots$, and more generally the McKay-Thompson series $T_g(\tau) = \sum_{n\in\mathbf{Z}} \mathrm{Tr}(g|V_n)q^n$ is a Hauptmodul for some genus 0 congruence subgroup of $SL_2(\mathbf{R})$. The representation V was constructed by Frenkel, Lepowsky, and Meurman [FLM], and it was shown to satisfy the moonshine conjectures in [B92] by using the fact that it carries the structure of a vertex algebra [B86], [FLM].

Meanwhile, Norton had suggested that there should be a graded space associated to every element g of the monster acted on by some central extension of the centralizer of g ([N], see also [Q]). It is easy to see that these graded spaces are usually unlikely to have a vertex algebra structure. Ryba suggested [R94] that these spaces might have a vertex algebra structure if they were reduced mod p (if g has prime order p). He also suggested the following definition for these vertex algebras:

$$^{g}V = \frac{V^g/pV^g}{(V^g/pV^g)\cap(V^g/pV^g)^{\perp}}$$

---

* Supported by NSF grant DMS-9401186.

where V is some integral form for the monster vertex algebra, and V^g is the set of vectors fixed by g. He conjectured that the dimensions of the homogeneous components of ${}^gV$ should be the coefficients of certain Hauptmoduls, and more generally that if h is a p-regular element of $C_M(g)$ then

$$\mathrm{Tr}(h|{}^gV_n) = \mathrm{Tr}(gh|V_n)$$

where the trace on the left is the Brauer trace. (The numbers on the right are known to be the coefficients of a Hauptmodul depending on gh by [B92].) We will call these conjectures the modular moonshine conjectures.

We now describe the proof of the modular moonshine conjectures for some elements g given in this paper. We observe (proposition 2.3) that the definition of ${}^gV$ in [R94] is equivalent to defining it to be the Tate cohomology group $\hat{H}^0(g, V)$, or at least it would be if a good integral form V of the monster Lie algebra was known to exist. The lack of a good integral form V does not really matter much, because we can just as well use a $\mathbf{Z}[1/n]$-form for any n coprime to $|g|$, and a $\mathbf{Z}[1/2]$-form can be extracted from Frenkel, Lepowsky and Meurman's construction of the monster vertex algebra.

It is difficult to work out the dimension of $\hat{H}^0(g, V[1/2]_n)$ directly. However it is easy to work out the difference of the dimensions of $\hat{H}^0$ and $\hat{H}^1$, which can be thought of as a sort of Euler characteristic (and is closely related to the Herbrand quotient in number theory). This suggests that we should really be looking at $\hat{H}^*(g, V[1/2]) = \hat{H}^0(g, V[1/2]) \oplus \hat{H}^1(g, V[1/2])$, and it turns out for essentially formal reasons that this has the structure of a vertex superalgebra. The traces of elements h of the centralizer of g on this superalgebra are just given by the traces of the elements gh on the monster vertex algebra.

We can now complete the proof of the modular moonshine conjectures for the element g of the monster by showing that $\hat{H}^1(g, V[1/2]) = 0$. We do this for certain elements of odd prime order of the monster coming from M_{24} in section 4; this is a long but straightforward calculation. There are plenty of elements g of the monster for which $\hat{H}^1(g, V[1/2])$ does not vanish; this happens whenever some coefficient of the Hauptmodul of g is negative; for example, g of type 3B. There are also some elements of large prime order for which we have been unable to prove the modular moonshine conjectures because we have not proved that $\hat{H}^1(g, V[1/2]) = 0$ (though this is probably true), but we do at least cover all the cases when g has prime order and its centralizer involves a sporadic simple group.

The case when $p = 2$ has several extra complications, due partly to the existence of several extensions of groups by 2-groups, and due partly to the fact the FLM construction can be carried out over $\mathbf{Z}[1/2]$ but it is not clear how to do it over $\mathbf{Z}$. We deal with these extra problems in section 5 by using a $\mathbf{Z}[1/3]$-form of the monster vertex algebra. To construct this $\mathbf{Z}[1/3]$-form we need to make a mild assumption (which we have not checked) about the construction of the monster vertex algebra from an element of order 3 announced by Dong and Mason and by Montague. (In particular the proof of the modular moonshine conjectures for elements of type 2A in the monster uses this assumption.)

In section 6 we give some calculations illustrating the case when g is an element of type 7A in the monster (so the centralizer $C_M(g)$ of g is $\langle g\rangle \times He$). We give the characters and the decomposition into irreducible modular representations of the first few graded pieces of $\hat{H}^0(g, V[1/2])$.

In section 7 we discuss some open problems, in particular how one might construct a good integral form of the monster vertex algebra.

Notation.

A^G	The largest submodule of A on which G acts trivially.
A_G	The largest quotient module of A on which G acts trivially.
A, B, C	G-modules.
Aut	The automorphism group of something.
B	The baby monster sporadic simple group.
$\mathbf{C}$	The complex numbers.
$C_M(g)$	The centralizer of g in the group M.
Fi_{24}	One of Fischer's groups.
$\mathbf{F_q}$	The finite field with q elements.
g	An element of G, usually of order p.
$\langle g\rangle$	The group generated by g.
G	A group, often cyclic of prime order p and generated by g.

$\hat{H}^i(G,A)$	A Tate cohomology group of the finite group G with coefficients in the G-module A.
$\hat{H}^i(g,A)$	means $\hat{H}^i(\langle g\rangle,A)$, where $\langle g\rangle$ is the cyclic group generated by g.
$\hat{H}^*(g,A)$	The sum of the Tate cohomology groups $\hat{H}^0(g,A)$ and $\hat{H}^1(g,A)$, considered as a super module.
He	The Held sporadic simple group.
HN	The Harada-Norton sporadic simple group.
I	The elements of a group ring of norm 0.
Im	The image of a map.
Ker	The kernel of a map.
$\Lambda, \hat{\Lambda}$	The Leech lattice and a double cover of the Leech lattice.
L	An even lattice.
M	The monster simple group.
M_{12}	A Mathieu group.
M_{24}	A Mathieu group.
N	The norm map: $N(v)=\sum_{g\in G} g(v)$.
$N_M(g)$	The normalizer of the subgroup $\langle g\rangle$ in the group M.
p	A prime, usually the order of g.
$\mathbf{R}$	The real numbers.
R_p	A finite extension of the p-adic integers.
$S(a)$	$=\sum_{0\le n<p} ng^n(a)$
SL_2	A special linear group.
Th	Thompson's sporadic simple group.
Tr	$\mathrm{Tr}(g\vert A)$ is the usual trace of g on a module A if A is a module over a ring of characteristic 0, and the Brauer trace if A is a module over a field of finite characteristic.
$V[1/n]$	A $\mathbf{Z}[1/n]$-form of the monster vertex algebra.
V_Λ	The integral form of the vertex algebra of $\hat{\Lambda}$.
V_n	The degree n piece of V.
V^n	An eigenspace of some group acting on V.
${}^gV$	A modular vertex algebra or superalgebra given by $\hat{H}^*(g,V[1/n])$ for some n coprime to $\vert g\vert$.
$\mathbf{Z}$	The integers.
$\mathbf{Z}_p$	The p-adic integers.
ω	A cube root of 1 or a conformal vector.

2. Cohomology and modular representations.

In this section we summarize some basic facts about group cohomology that we will use later. For more details about Tate cohomology groups see the article [AW].

If G is a finite group acting on an abelian group A we define A^G to be the elements of A fixed by G, and A_G to be the largest quotient of A on which G acts trivially. We write N for the norm map defined by $N(a)=\sum_{g\in G} g(a)$. If n is any integer then $\hat{H}^n(G,A)$ is the Tate cohomology group of G with coefficients in A. It has the following properties.

1. $\hat{H}^0(G,A)=A^G/\mathrm{Im}(N)$.
2. $\hat{H}^{-1}(G,A)=\mathrm{Ker}(N|A_G)$.
3. If $0\to A\to B\to C\to 0$ is an exact sequence of G modules then
$$\cdots\longrightarrow \hat{H}^{i-1}(G,C)\longrightarrow \hat{H}^i(G,A)\longrightarrow \hat{H}^i(G,B)\longrightarrow \hat{H}^i(G,C)\longrightarrow \hat{H}^{i+1}(G,A)\longrightarrow \hat{H}^{i+1}(G,B)\longrightarrow\cdots$$
is exact.
4. There is a bilinear cup product from $\hat{H}^i(G,A)\times\hat{H}^j(G,B)$ to $\hat{H}^{i+j}(G,C)$, defined whenever we have a G-invariant bilinear map from $A\times B$ to C, and which is the obvious induced product when $i=j=0$. $\hat{H}^*(G,\mathbf{Z})$ is a super-commutative ring under cup product. More generally if A has any G-invariant algebraic structure defined in terms of multilinear products and multilinear identities (e.g., commutative ring, Lie algebra, vertex algebra, etc.) then $\hat{H}^*(G,A)=\oplus_{n\in\mathbf{Z}}\hat{H}^n(G,A)$ is a "super" version of this algebraic structure under the cup product; this means that it satisfies the same identities as A except that we insert a factor of -1 whenever we interchange the order of two elements of odd degree. This follows from the associativity and supercommutativity properties of the cup product given in [AW]. For

example, if A is a Lie algebra, then $\hat{H}^*(G,A)$ is a Lie superalgebra (at least if A is 2-divisible so that the Lie algebra axioms can all be written as multilinear identities).

5. If G is a cyclic group generated by an element g we will also write the cohomology groups $\hat{H}^i(G,A)$ as $\hat{H}^i(g,A)$. In this case $\hat{H}^2(g,\mathbf{Z})$ has a canonical element (depending on the generator g) such that cup product by this element is an isomorphism from $\hat{H}^i(g,A)$ to $\hat{H}^{i+2}(g,A)$. In particular there are essentially only 2 different cohomology groups, $\hat{H}^0$ and $\hat{H}^1$, as all the others are isomorphic to one of these two, so we define $\hat{H}^*(g,A)$ to be $\hat{H}^0(g,A)\oplus\hat{H}^1(g,A)$. As in 4 above, if A has some algebraic structure, then $\hat{H}^*(g,A)=\hat{H}^0(g,A)\oplus\hat{H}^1(g,A)$ has a super version of this algebraic structure, with $\hat{H}^0$ and $\hat{H}^1$ being the even and odd parts. Notice that the algebra product from $\hat{H}^1\times\hat{H}^1$ to $\hat{H}^0$ depends on the choice of generator g because it uses the isomorphism from $\hat{H}^2$ to $\hat{H}^0$. In particular if $g\in G$ and A has an algebra structure invariant under G, then the natural action of the normalizer $N_G(g)$ on $\hat{H}^*(g,A)$ need not preserve the algebra structure (unless of course $\hat{H}^1(g,A)=0$). The centralizer $C_G(g)$ always preserves the algebra structure. We always regard $\hat{H}^*(g,A)$ as a supermodule, and in particular when we take the trace of an element h on it we multiply the trace on $\hat{H}^1$ by -1, i.e., $\mathrm{Tr}(h|\hat{H}^*(g,A))$ is defined to be $\mathrm{Tr}(g|\hat{H}^0(g,A))-\mathrm{Tr}(g|\hat{H}^1(g,A))$. (The trace will always be the Brauer trace, which takes values in a field of characteristic 0.)
6. $\hat{H}^*(G,A)$ is a $|G|$-torsion module, and in particular if multiplication by $|G|$ is an isomorphism on A then $\hat{H}^*(G,A)$ vanishes.

We let $\mathbf{Z}_p$ be the ring of p-adic integers.

Lemma 2.1. *If A is a free $\mathbf{Z}[1/n]$ module acted on by a p-group G with $(p,n)=1$ then the natural map from $\hat{H}^*(G,A)$ to $\hat{H}^*(G,A\otimes\mathbf{Z}_p)$ is an isomorphism.*

Proof. This follows by looking at the long exact sequence of $0\to A\to A\otimes\mathbf{Z}_p\to A\otimes(\mathbf{Z}_p/\mathbf{Z}[1/n])\to 0$, if we observe that multiplication by p is an isomorphism on $\mathbf{Z}_p/\mathbf{Z}[1/n]$ so the cohomology of $A\otimes(\mathbf{Z}_p/\mathbf{Z}[1/n])$ vanishes. This proves lemma 2.1.

Now suppose that G is a cyclic group of order p generated by g. Recall ([CR] p. 690) that there are exactly 3 indecomposable finitely generated modules over the group ring $\mathbf{Z}_p[G]$ which are free as $\mathbf{Z}_p$ modules; these are:

1. The 1-dimensional module $\mathbf{Z}_p$ (with g acting trivially). The cohomology groups of G with coefficients in $\mathbf{Z}_p$ are $\hat{H}^0(g,\mathbf{Z}_p)=\mathbf{Z}/p\mathbf{Z}$, $\hat{H}^1(g,\mathbf{Z}_p)=0$, as can be easily checked by explicit calculation.
2. The group ring $\mathbf{Z}_p[G]$. All cohomology groups of this module are trivial as it is a projective module.
3. The module I, which is the kernel of the natural map from $\mathbf{Z}_p[G]$ to $\mathbf{Z}_p$. The cohomology groups of I can be worked out from the long exact sequence of $0\to I\to\mathbf{Z}_p[G]\to\mathbf{Z}_p\to 0$, and are given by $\hat{H}^0(g,I)=0$, $\hat{H}^1(g,I)=\mathbf{Z}/p\mathbf{Z}$.

The next proposition is the main tool for calculating the Brauer characters of the modular vertex algebras we will construct.

Proposition 2.2. *Suppose that A is a finitely generated free module over $\mathbf{Z}_p$ (or over $\mathbf{Z}$) acted on by a group G containing an element g of order p in its center. Then the Brauer character of the virtual modular representation $\hat{H}^*(g,A)=\hat{H}^0(g,A)-\hat{H}^1(g,A)$ of $G/\langle g\rangle$ is given by*

$$\mathrm{Tr}(h|\hat{H}^*(g,A))=\mathrm{Tr}(gh|A)$$

for any p-regular element h of G. (The left hand trace is the Brauer trace, and the right hand one is the usual trace.)

Proof. We can assume that G is the product of the cyclic groups generated by g and h. We adjoin the $|h|$'th roots of 1 to $\mathbf{Z}_p$ to obtain an unramified extension R_p of $\mathbf{Z}_p$. It is sufficient to prove the proposition for the module $A\otimes R_p$ because both sides are unaffected by tensoring A by R_p. (The Brauer trace of the cohomology groups is of course calculated by regarding them as modules over the residue class field of R_p.) We can decompose $A\otimes R_p$ into eigenspaces for h, and as both traces are additive on modules we can assume that h acts on $A\otimes R_p$ as multiplication by some fixed root of unity ζ.

Both sides of proposition 2.2 are additive on short exact sequences (the additivity for the left hand side follows from the "exact hexagon" of Tate cohomology). The only irreducible representations of $Q\otimes R_p[g]$ over the quotient field $Q\otimes R_p$ of R_p are $Q\otimes R_p$ and $Q\otimes I\otimes R_p$, which implies that the module A can be built from $I \otimes R_p$, R_p, and finite modules by taking repeated extensions. By additivity it is then sufficient to prove proposition 2.2 in the cases when A is $I \otimes R_p$ or R_p or a finite module. The case when A is finite is trivial as both sides are zero (the dimensions of $\hat{H}^0(g, A)$ and $\hat{H}^1(g, A)$ are equal because the Herbrand quotient $|\hat{H}^0(g, A)|/|\hat{H}^0(g, A)|$ is 1 for finite modules A).

We have reduced the proof of proposition 2.2 to checking the 2 cases when $A \otimes R_p$ is R_p or $I \otimes R_p$, and where h acts as multiplication by ζ. If $A \otimes R_p$ is R_p, then $\hat{H}^0(g, R_p) = R_p/pR_p$, and $\hat{H}^1(g, A \otimes R_p) = 0$, so $\mathrm{Tr}(h|\hat{H}^*(R_p)) = \zeta$, which is equal to $\mathrm{Tr}(gh|R_p) = \mathrm{Tr}(h|R_p)$. If $A \otimes R_p$ is the group ring $R_p[g]$, then both cohomology groups are 0 and the trace of gh on $R_p[g]$ is also 0 as the eigenvalues of gh are ζ multiplied by every p'th root of 1 (including 1). Finally the case when $A \otimes R_p = I \otimes R_p$ follows from the previous two cases and the exact sequence

$$0 \longrightarrow I \otimes R_p \longrightarrow R_p[g] \longrightarrow R_p \longrightarrow 0$$

because both traces are additive on short exact sequences. This proves proposition 2.2.

If A is a finitely generated free module over a ring R with a bilinear form $(,)$, then we say this form is self dual if every linear map f from A to R is of the form $f(a) = (a, b)$ for some fixed $b \in A$. If the form is symmetric and R is the ring of integers this is equivalent to saying that A is a unimodular lattice. We say the bilinear form is nonsingular if there is no nonzero element a with $(a, b) = 0$ for all $b \in A$. We say that a submodule B of A is primitive if A/B is torsion free.

Proposition 2.3. *Suppose A is a free $\mathbf{Z}$ or $\mathbf{Z}_p$ module acted on by the finite group G of order p with an invariant self dual symmetric bilinear form $(,)$. Then $N(A)$ is the set of all elements $a \in A^G$ such that $p|(a, b)$ for all $b \in A^G$. In particular the bilinear form $(,)$ induces a nonsingular bilinear form on $\hat{H}^0(G, A)$.*

Proof. We will prove this when A is a free $\mathbf{Z}$-module; the proof when A is a free $\mathbf{Z}_p$ module is similar. We think of A as a lattice in the real vector space $A \otimes \mathbf{R}$, which also has a nonsingular bilinear form induced by that of A. Note that $A \otimes \mathbf{R}$ is the orthogonal direct sum of the subspaces $A^G \otimes \mathbf{R}$ and $\mathrm{Ker}(N)$, so the bilinear form is nonsingular on each of these subspaces. The map N is just p times orthogonal projection onto the subspace $(A \otimes \mathbf{R})^G$. Hence $\frac{1}{p}N(A)$ is just the orthogonal projection of A into $(A \otimes \mathbf{R})^G$. The sublattice A^G is also primitive because if na is fixed by G for some nonzero $n \in \mathbf{Z}$ then so is a. On the other hand, the set of vectors $a \in A^G$ such that $p|(a, b)$ for all $b \in A^G$ is the same as $p(A^{G'})$ (where B' means the dual of the lattice B, i.e., the set of all vectors of $B \otimes \mathbf{R}$ which have integral inner product with all elements of B). For any nonsingular primitive sublattice B of A, and in particular for $B = A^G$, B' is the projection of A into $B \otimes \mathbf{R}$ because the bilinear form on A is self dual. (As B is a primitive sublattice of A the natural map from A' to B' is surjective, so as A is self dual and can be identified with A' we see that the projection from A to B' is surjective.) This proves proposition 2.3.

There is a similar but slightly more complicated result for $\hat{H}^1$.

Proposition 2.4. *Suppose A is a free $\mathbf{Z}$ or $\mathbf{Z}_p$ module with an invariant self dual symmetric bilinear form $(,)$ acted on by the finite group G generated by g of order p. Define a bilinear form $\langle a, b\rangle$ on A by $\langle a, b\rangle = (S(a), b)$ where $S(a) = \sum_{0 \le n < p} ng^n(a)$. Then A_G is the quotient of A by the set C of all elements $a \in \mathrm{Ker}(N)$ such that $p|\langle a, b\rangle$ for all $b \in \mathrm{Ker}(N)$. In particular the bilinear form $\langle,\rangle$ induces a nonsingular antisymmetric bilinear form on $\hat{H}^1(G, A)$.*

Proof. Some easy calculations show (even if we do not assume $(,)$ is self dual) that $\langle,\rangle$ is antisymmetric mod$p$, that $S(a) - S(g(a)) = N(a) - pa$, that $N(S(a)) = (p-1)pN(a)/2$, and that the kernel of the map from A to A_G (i.e., the module generated by elements of the form $a - g(a)$) is contained in C.

Suppose $a \in C$; we want to deduce that $a = b - g(b)$ for some $b \in A$. We know that $N(S(a)) = 0$ (because $N(a) = 0$), and $p|(S(a), b)$ for all b with $N(b) = 0$. Hence $S(a)/p$ lies in $\mathrm{Ker}(N)'$. The submodule $\mathrm{Ker}(N)$ is a primitive nonsingular submodule of the self dual module A, so $S(a)/p$ lies in the orthogonal projection of A into $\mathrm{Ker}(N) \otimes \mathbf{R}$, i.e., $S(a)/p = b - N(b)/p$ for some $b \in A$. But this means that $S(a) = S(g(b)) - S(b)$, so that $S(a - b + g(b)) = 0$. But S is injective, as we can see by checking that it multiplies every eigenvector of g by a nonzero constant, so $a - b + g(b) = 0$. This proves proposition 2.4. (It is easy to see that $\hat{H}^1(G, A)$ has an antisymmetric $\mathbf{Z}/p\mathbf{Z}$-valued bilinear form induced from the cup product and the bilinear form on A, followed by the isomorphism from $\hat{H}^2(G, \mathbf{Z})$ to $\hat{H}^0(G, \mathbf{Z})$. The main point of the proof above is that this antisymmetric form is self dual when the form on A is self dual.)

3. Vertex superalgebras mod p.

In this section we will construct a vertex superalgebra for every element of odd prime order in the monster.

If R is a subring of the complex numbers $\mathbf{C}$, then by an R-form of the monster vertex algebra we mean a graded vertex algebra defined over R which is a free R module, and which becomes isomorphic to the FLM monster vertex algebra when it is tensored with $\mathbf{C}$, and which is acted on by the monster and contains a conformal vector (the components of whose vertex operator generate the Virasoro algebra). We say that an R-form is self dual if the natural bilinear form on the FLM algebra restricts to a self dual R-valued bilinear form on each homogeneous piece.

We let $V[1/2]$ be the $\mathbf{Z}[1/2]$-form of the monster vertex algebra constructed in theorem 3.2 below.

Theorem 3.1. *If g is an element of the monster of odd prime order p then $\hat{H}^*(g, V[1/2]) = \hat{H}^0(g, V[1/2]) \oplus \hat{H}^1(g, V[1/2])$ is a $\mathbf{Z}$-graded vertex superalgebra over $\mathbf{Z}/p\mathbf{Z}$, acted on by $C_M(g)/\langle g\rangle$. It has a nonsingular supersymmetric bilinear form that is invariant under $C_M(g)/\langle g\rangle$. If $h \in C_M(g)$ is p-regular then $\sum_{n\in\mathbf{Z}} \mathrm{Tr}(h|\hat{H}^*(g, V[1/2]_n))q^n$ is a Hauptmodul for some genus 0 subgroup of $SL_2(\mathbf{R})$, and is equal to the Hauptmodul of the element gh of M.*

Proof. The fact that $\hat{H}^*(g, V[1/2])$ is a vertex superalgebra follows from the remarks about group cohomology in the previous section. The nonsingularity of the supersymmetric bilinear form follows from propositions 2.3 and 2.4. The fact that the trace of g is a Hauptmodul follows from proposition 2.2 together with the result of [B92] that the series $\sum_{n\in\mathbf{Z}} \mathrm{Tr}(g|V_n)q^n$ is a Hauptmodul for any element $g \in M$. This proves theorem 3.1.

Remark. The bilinear form in theorem 3.1 is also compatible with the vertex algebra structure (where this notion is defined in the discussion below), but we will not use this fact.

Proposition 2.3 also shows that $\hat{H}^0(g, V[1/2])$ is isomorphic to the space ${}^gV = V^g/pV^g/((V^g/pV^g) \cap (V^g/pV^g)^\perp)$ suggested in [R94].

In the rest of this section we recall some results about vertex algebras from [B86] and give the construction of the $\mathbf{Z}[1/2]$-form $V[1/2]$ of the monster vertex algebra. The only serious use we make of vertex algebra structures is to use them to construct other modular vertex algebras, so the reader who wishes to ignore vertex algebras completely and only see the proof that the traces of various group elements are Hauptmoduls can replace the words "vertex algebra" by "graded vector space" without losing much. Similarly the conformal vectors and bilinear forms on vertex algebras are used mainly to construct conformal vectors and bilinear forms on modular vertex algebras, so the reader can ignore all the discussion of these.

We recall the definition of a vertex algebra over any commutative ring R. The definition we give here is equivalent to that given in [B86]. If V is an R module we define a vertex operator $a(z)$ on V to be a sequence of linear operators a_n for $n \in \mathbf{Z}$ on V, with the property that for any $b \in V$, $a_nb = 0$ for n sufficiently large (depending on a and b). We put these operators into the formal Laurent series $a(z) = \sum_{n\in\mathbf{Z}} z^n a_{-n-1}$. Then a vertex algebra over R is an R module V together with an element $1 \in V$ and a vertex operator $a(z)$, acting on V, for each $a \in V$, such that the following conditions are satisfied for any $a, b \in V$.

1. $1(z) = 1$, and $a(0)1 = a$ (i.e., $a_n1 = 0$ if $n \geq 0$ and $a_{-1}1 = a$).
2. The vertex operators $a(z)$ and $b(y)$ formally commute, in the sense that we can find $n \geq 0$ (depending on a and b) such that all coefficients of monomials x^iy^j of

$$(x - y)^n(a(x)b(y) - b(y)a(x))$$

   are zero. (For a vertex superalgebra we replace $b(y)a(x)$ by $(-1)^{(\deg(a),\deg(b))}b(y)a(x)$.)
3. We denote the element $a_{-n-1}1$ by $D^{(n)}(a)$. Then $(D^{(n)}a)(z) = ((\frac{d}{dz})^n/n!)a(z)$.

This is similar to a definition of commutative associative algebras over R: we can define these as R modules V such that for every $a \in V$ we are given an operator a_L on V and an element $1 \in V$ with the properties that $1_La = a_L1 = a$, and the operators a_L and b_L commute for all $a, b \in V$. This shows that a vertex algebra can be thought of as a "commutative ring with singularities in the multiplication".

The operators $D^{(n)}$ have the properties $D^{(0)}(a) = a$, $D^{(m)} = 0$ if $m < 0$, and $D^{(m)}D^{(n)} = \binom{m+n}{m}D^{(m+n)}$.

We briefly recall the structure of the integral form V_Λ of the vertex algebra of Λ from [B86]. The lattice Λ has a certain nonsplit central extension $\hat{\Lambda}$ (in which the group operation is written multiplicatively) such that if we denote a lifting of $a \in \Lambda$ by $e^a \in \hat{\Lambda}$, then $e^a e^b = (-1)^{(a,b)} e^b e^a$ so we get an exact sequence

$$0 \longrightarrow \pm 1 \longrightarrow \hat{\Lambda} \longrightarrow \Lambda \longrightarrow 0.$$

The automorphism group of $\hat{\Lambda}$ preserving the inner product on Λ is a nonsplit extension of the form $2^{24}.\mathrm{Aut}(\Lambda)$ which acts on the vertex algebra V_Λ of Λ (which really depends on $\hat{\Lambda}$ rather than Λ). V_Λ is graded by Λ in such a way that e^a has degree $a \in \Lambda$, it has an underlying ring structure which is "graded commutative", i.e., $ab = (-1)^{(\deg(a),\deg(b))} ba$ if a and b are homogeneous elements with Λ-degrees $\deg(a)$ and $\deg(b)$, and it has a derivation with divided powers, i.e., a set of additive operations $D^{(m)}$ for $m \in \mathbf{Z}$ such that $D^{(0)}(a) = a$, $D^{(m)}D^{(n)} = \binom{m+n}{m} D^{(m+n)}$, $D^{(m)} = 0$ if $m < 0$, and $D^{(n)}(ab) = \sum_{m \in \mathbf{Z}} (D^{(m)}(a)) D^{(n-m)}(b)$. The derivation D has Λ-degree 0; in other words $D^{(m)}(a)$ has the same Λ-degree as a. The graded-commutative ring V_Λ contains a copy of the twisted group ring of Λ which has a basis of elements denoted by e^a for $a \in \Lambda$ with the properties that $e^a e^b = \pm e^{a+b}$, $e^a e^b = (-1)^{(a,b)} e^b e^a$, and can be defined as the universal graded-commutative ring with a derivation with divided powers generated by this group ring. The subring $V_{\Lambda,0}$ of elements of V_Λ with Λ-degree 0 is generated as a commutative ring by elements of the form $(e^a)^{-1} D^{(i)}(e^a)$ for $a \in \Lambda$, $i \geq 1$.

A conformal vector of dimension (or "central charge") $c \in \mathbf{R}$ of a vertex algebra V is defined to be an element ω of V such that $\omega_0 v = D(v)$ for any $v \in V$, $\omega_1 \omega = 2\omega$, $\omega_3 \omega = c/2$, $\omega_i \omega = 0$ if $i = 2$ or $i > 3$, and any element of V is a sum of eigenvectors of the operator $L_0 = \omega_1$ with integral eigenvalues. If v is an eigenvector of L_0, then its eigenvalue is called the (conformal) weight of v. If v is an element of the monster vertex algebra V of conformal weight n, we say that v has degree $n-1$ $(= n - c/24)$, and we write V_n for the module of elements of V of degree n.

The $\mathbf{R}$-form of the vertex algebra of any c-dimensional even lattice L has a canonical conformal vector $\omega = \sum_i a_i(1)a_i(1)/2$ of dimension c, where the elements a_i run over an orthonormal basis of $L \otimes \mathbf{R}$ and the monster vertex algebra has a conformal vector of dimension 24. If ω is a conformal vector of a vertex algebra V then we define operators L_i on V for $i \in \mathbf{Z}$ by

$$L_i = \omega_{i+1}.$$

These operators satisfy the relations

$$[L_i, L_j] = (i-j)L_{i+j} + \binom{i+1}{3} \frac{c}{2} \delta^i_{-j}$$

and so make V into a module over the Virasoro algebra. The operator L_{-1} is equal to D.

The vertex algebra of any even lattice L has a real valued symmetric bilinear form (,) such that the adjoint of the operator u_n is $(-1)^i \sum_{j \geq 0} L_1^j (\sigma(u))_{2i-j-n-2}/j!$ if u has degree i, where σ is the automorphism of the vertex algebra defined by $\sigma(e^w) = (-1)^{(w,w)/2}(e^w)^{-1}$ for e^w an element of the twisted group ring of L corresponding to the vector $w \in L$. Similarly the monster vertex algebra has a real valued symmetric bilinear form (,) such that the adjoint of the operator u_n is $(-1)^i \sum_{j \geq 0} L_1^j (u)_{2i-j-n-2}/j!$ if u has degree i. If a vertex algebra has a bilinear form with the properties above we say that the bilinear form is compatible with the conformal vector. If a vertex algebra does not have a conformal vector but only a $\mathbf{Z}$-grading we can still define compatible bilinear forms, because we can define the operator $L_1^j/j!$ to be the adjoint of the operator $L_{-1}^i/i! = D^{(i)}$. (If we are not in characteristic 0 we have to modify these definitions slightly by replacing $L_1^i/i!$ by a system of divided powers of L_1 satisfying some conditions.)

The integral form V_Λ of the vertex algebra of the Leech lattice contains the conformal vector $\omega = \sum_{1 \leq i \leq 24} a_i(1)a_i(1)/2$ where the a_i's run over an orthogonal basis of $\Lambda \otimes \mathbf{R}$ because we can rewrite this as $\omega = \sum_{1 \leq i < j \leq 24} a_i(1)a_j(1)(a'_i, a'_j) + \sum_{1 \leq i \leq 24} a_i(1)a_i(1)(a'_i, a'_i)/2$ where the a_i's run over a basis of Λ and the a'_i's are the dual basis. The elements a'_i have integral inner products and even norms because they all lie in Λ as Λ is unimodular. In general the same argument shows that the conformal vector of any even integral unimodular lattice lies in the integral form of its vertex algebra; this is usually false for lattices that are not unimodular and even. The bilinear form on the integral form V_Λ is self dual (section 2, (vi) of [B86]), and in fact the same is true if Λ is replaced by any even unimodular lattice.

For working out values of the bilinear form in V_Λ it is useful to note that $(a(1)b(1), c(1)d(1)) = (a,c)(b,d) + (a,d)(b,c)$ for $a, b, c, d \in \Lambda$. In particular the conformal vector ω has norm $(\omega, \omega) = \dim(\Lambda)/2 = 12$.

Theorem 3.2. *There is a* $\mathbf{Z}[1/2]$*-form* $V[1/2]$ *of the monster vertex algebra with a conformal vector and a self dual bilinear form such that* $V[1/2]$ *can be written as a direct sum of* $2^{12}.M_{24}$ *modules each of which is isomorphic to a submodule of the* $\mathbf{Z}[1/2]$*-form* $V_\Lambda[1/2]$ *of* V_Λ*.*

Proof. Frenkel, Lepowsky and Meurman construct the monster vertex algebra as a complex vector space. However their construction almost works over the integers (if we use the integral form of V_Λ above) except that they often need to decompose vector spaces into eigenspaces of abelian groups of order 2. This can be done over $\mathbf{Z}[1/2]$ (proof: $a = \frac{a+h(a)}{2} + \frac{a-h(a)}{2}$). A precise definition of this $\mathbf{Z}[1/2]$-form $V[1/2]$ of the monster vertex algebra is given implicitly in the next 2 paragraphs.

The $\mathbf{Z}[1/2]$-form $V[1/2]$ of the monster vertex algebra splits as the sum $V^0 \oplus V^1$ of the $+1$ and -1 eigenspaces of an element $h \in M$ of type 2B. As modules over $\mathrm{Aut}(\hat{\Lambda}) = 2^{24}.\mathrm{Aut}(\Lambda)$, V^0_Λ and V^0 are isomorphic, where V^0_Λ is the subalgebra of $V_\Lambda[1/2]$ fixed by the automorphism σ.

To construct the action of the monster on $V[1/2]$, Frenkel, Lepowsky, and Meurman split it further as $V[1/2] = V^{00} \oplus V^{01} \oplus V^{10} \oplus V^{11}$ where the V^{ij}'s are the eigenspaces of a 2^2-group in the monster containing h, and can be taken as free $\mathbf{Z}[1/2]$ modules. The modules V^0 and V^1 decompose as $V^0 = V^{00} \oplus V^{01}$, $V^1 = V^{10} \oplus V^{11}$. Frenkel, Lepowsky, and Meurman construct a triality automorphism σ that maps V^{00} to itself, transitively permutes the modules V^{01}, V^{10}, and V^{11}, and commutes with the elements of the group $2^{12}.M_{24} \subset \mathrm{Aut}(\hat{\Lambda})$. We use the isomorphism defined by σ between these 3 modules to transport the $\mathbf{Z}[1/2]$-form from V^{01} to V^{10}, and V^{11}, which defines the $\mathbf{Z}[1/2]$-form $V[1/2] = V^{00} \oplus V^{01} \oplus V^{10} \oplus V^{11}$. In particular σ commutes with $2^{12}.M_{24}$, so that V^{01}, V^{10}, and V^{11} are all isomorphic as modules over this group.

The conformal vector of $V[1/2]$ is just the conformal vector of $V^0 \subset V_\Lambda[1/2]$ (which is fixed by h). The self dual bilinear form on V_Λ induces a self dual bilinear form on V^0 over $\mathbf{Z}[1/2]$, which restricts to self dual forms on V^{01} and V^{00}, which give self dual forms on V^{10} and V^{11} by using the triality automorphism to transport the self dual form from V^{01}. This defines the self dual form on $V[1/2]$. This proves theorem 3.2.

4. A vanishing theorem for cohomology.

For every element g of the monster (or at least for those of odd order) we have constructed a vertex superalgebra $\hat{H}^*(g, V)$ acted on by $C_M(g)$ whose McKay-Thompson series are Hauptmoduls. For some elements g we will now show that the first cohomology group vanishes, so in fact we have constructed a modular vertex algebra satisfying the modular moonshine conjectures for the element g. It is certainly not true that $\hat{H}^1(g, V)$ vanishes for all elements g; by proposition 2.2 a necessary condition is that all coefficients of the Hauptmodul of g are nonnegative. This may be a sufficient condition but we do not know how to prove this in general. We will prove it is sufficient if g is an element of odd order coming from an element of M_{24}. This covers the cases of the conjugacy classes 3A, 3C, 5A, 7A, 11A, 15A, 21A, and 23A of the monster. In section 5 we will prove a similar theorem for elements of type 2A (under a mild assumption).

We will call a free R-module A acted on by a group G a permutation module if it has a basis that is closed under the action of G.

Lemma 4.1. *If* A *is a permutation module of a finite group* G *over a ring* R *with no* $|G|$ *torsion then* $\hat{H}^{-1}(G, A) = 0$*.*

Proof. We can assume that A comes from a transitive permutation representation of G, as all permutation representations are sums of transitive ones. Suppose S is the set of elements in the permutation representation, so that S is a basis for A. We have to show that $\mathrm{Ker}(N)$ is spanned by elements of the form $a - g(a)$. But $\mathrm{Ker}(N)$ is the set of elements $\sum_{s\in S} a_s s$ with $\sum_{g\in G} a_{g(s)} = 0$ (for some fixed $s \in S$), which is the set of elements with $\sum_{s\in S} a_s = 0$ because A has no $|G|$ torsion. But this space is obviously spanned by the set of elements of the form $s - g(s)$ as G acts transitively on S. This proves lemma 4.1.

Lemma 4.2. *The set of permutation modules is closed under taking sums, tensor products, and symmetric powers.*

Proof. The operations of taking sums or tensor products correspond to taking unions and products on the permutation representations. The operation of taking a symmetric n'th power of a representation corresponds to taking the set of "multisubsets" of cardinality n of a permutation representation S. (A multisubset is like a subset except that we are allowed to take several copies of some element.) This proves lemma 4.2.

Remark. If A is a permutation module for G coming from a permutation in which every element of G acts as an even permutation then all exterior powers of A are permutation modules for G. In particular if G has odd prime order then the set of permutation modules is closed under taking exterior powers, but this is false when G has order 2.

Lemma 4.3. *If A is a free $\mathbf{Z}_p$ module acted on by the group G generated by an element g of order p, then $\hat{H}^1(g, A) = 0$ if and only if A is a permutation module of G.*

Proof. If A is a permutation module then $\hat{H}^1(g, A)$ vanishes by lemma 4.1 (using the fact that $\hat{H}^{-1}$ is isomorphic to $\hat{H}^1$ for cyclic groups). Conversely if $\hat{H}^1(g, A)$ vanishes then A is a sum of the indecomposable representations $\mathbf{Z}_p$ and $\mathbf{Z}_p[G]$ (because the other indecomposable representation $I \otimes \mathbf{Z}_p$ has nonvanishing $\hat{H}^1$ by the remarks after lemma 2.1), and these are both permutation modules of G. This proves lemma 4.3.

Lemma 4.4. *The free modules over $\mathbf{Z}_p$ acted on by $G = \mathbf{Z}/p\mathbf{Z}$ with vanishing $\hat{H}^1$ are closed under taking sums, products, and symmetric powers.*

Proof. This follows immediately from lemmas 4.2 and 4.3.

Lemma 4.5. *If g is an element of odd prime order p in $M_{24} \subset \mathrm{Aut}(\Lambda)$ (where Λ is the Leech lattice) then $\hat{H}^1(g, \Lambda) = \hat{H}^1(g, \Lambda \otimes \mathbf{Z}_p) = 0$.*

Proof. This follows from lemmas 2.1 and 4.1 and the fact that as a representation of M_{24}, $\Lambda \otimes R$ is isomorphic to the representation coming from the usual permutation representation of M_{24} whenever R contains $1/2$, and in particular whenever R is the ring of p-adic integers for p an odd prime. (Recall that the Leech lattice Λ contains a set of 24 pairwise orthogonal vectors of squared length 8 which are acted on by M_{24} as the standard permutation of M_{24} and which generate the $Z[1/2]$-module $\Lambda \otimes Z[1/2]$.) This proves lemma 4.5.

Theorem 4.6. *Suppose g is an element of odd prime order p in $\mathrm{Aut}(\Lambda)$ such that $\hat{H}^1(g, \Lambda) = 0$. Then $\hat{H}^1(g, V_\Lambda) = 0$.*

Proof. Recall from section 3 that there is an integral form V_Λ of the vertex algebra of Λ, which is graded by Λ.

We will show that the sum of the degree-λ pieces $V_{\Lambda,\lambda}$ of V_λ for λ running over the elements of some orbit of G on Λ has vanishing first cohomology, which will prove theorem 4.6. If λ is not fixed by g then the sum of the spaces $V_{\Lambda,g^i(\lambda)}$ is a free module over the group ring of G and so all its cohomology groups vanish. Hence we may assume that λ is fixed by g. In this case, $V_{\Lambda,\lambda}$ is isomorphic to the degree 0 piece $V_{\Lambda,0}$ as a G module (under multiplication by e^λ). (At this point we are implicitly using the fact that g has odd order to deduce that g fixes e^λ whenever g fixes λ; if g has even order we need to be more careful.) Hence we have reduced the proof of theorem 4.6 to showing that $\hat{H}^1(g, V_{\Lambda,0}) = 0$, or equivalently to showing that $\hat{H}^1(g, V_{\Lambda,0} \otimes \mathbf{Z}_p) = 0$.

By assumption on g and by lemma 4.3 we can choose a basis $a_1, \ldots, a_{24}$ of $\Lambda \otimes \mathbf{Z}_p$ such that the action of g on $\Lambda \otimes \mathbf{Z}_p$ is given by some permutation representation on this basis. The ring $V_{\Lambda,0}$ is the polynomial ring over $\mathbf{Z}_p$ generated by the elements $e^{-a_j} D^{(i)}(e^{a_j})$ for $i \geq 1$, $1 \leq j \leq 24$. This polynomial ring, considered as a representation of G over $\mathbf{Z}_p$, is a direct sum of products of symmetric powers of $\Lambda \otimes \mathbf{Z}_p$, so by lemma 4.4 its first cohomology vanishes. This proves theorem 4.6. (Warning: $V_{\Lambda,0}$ is strictly larger than the polynomial ring generated by the elements $D^{(i)}(a_j)$ for $i \geq 1$, $1 \leq j \leq 24$.)

Theorem 4.7. *Suppose g is an element of the monster of type 3A, 3C, 5A, 7A, 11A, or 23A, and let $V[1/2]$ be the $\mathbf{Z}[1/2]$-form of the monster vertex algebra constructed in 3.2. Then $\hat{H}^1(g, V[1/2]) = 0$.*

Proof. The element g in the monster commutes with an element h of type 2B because it can be seen from the monster character table in [C] that the monster always has an element of order $2p$ (and type 6C, 6F, 10B, 14B, 22B, or 46A) whose square is in the conjugacy class pA or 3C of g and whose p'th power is of type 2B. The centralizer of h is a group with structure $2^{1+24}.Co_1$, which contains a split extension of M_{24} by a 2-group of the form $2^{1+24}.2^{12}$. We can identify g with an element of this M_{24} group.

In particular we can consider g to be an element of $\mathrm{Aut}(\hat{\Lambda})$, so that it acts on the integral form V_Λ of the vertex algebra of the Leech lattice Λ. The 1st cohomology of g with coefficients in any direct summand of $V_\Lambda \otimes \mathbf{Z}[1/2]$ must also vanish, as it is a direct summand of $\hat{H}^1(g, V_\Lambda[1/2]) = 0$. By theorem 3.2, $V[1/2]$ is a direct sum of modules (V^{00}, V^{01}, V^{10}, and V^{11}) which are isomorphic as modules over g to direct summands of $V_\Lambda[1/2]$, so $\hat{H}^1(g, V[1/2]) = 0$. This proves theorem 4.7.

Corollary 4.8. *(The modular moonshine conjectures [R94] for the primes 3, 5, 7, 11, 23.) Suppose g is an element of order p in one of the conjugacy classes 3A, 3C, 5A, 7A, 11A, or 23A of the monster. Then there is a vertex algebra ${}^gV = \oplus_n {}^gV_n$ defined over the field with p elements with the following properties.*

1 *If g is not in the class 3C then ${}^gV_2$ contains a conformal vector (generating an action of the mod p Virasoro algebra) and has a nonsingular bilinear form compatible with the vertex algebra structure.*

2 *${}^gV$ is acted on by the group $C_M(g)/\langle g\rangle$, and this action preserves the conformal vector and the bilinear form.*

3 *The Brauer trace $\sum_n \mathrm{Tr}(h|{}^gV_n)q^n$ of any p-regular element h of $C_M(g)/\langle g\rangle$ on ${}^pV$ is a Hauptmodul, and is equal to the Hauptmodul of the element gh of the monster.*

Everything in corollary 4.8 except for the existence of a conformal vector follows from 4.7 and other things stated above. To show the existence of a conformal vector it is sufficient to show that the image of the conformal vector ω in $V[1/2]$ is nonzero, and to do this it is sufficient to find some vector fixed by g that has nonzero inner product with $\omega(\mathrm{mod} p)$. We let $a_1, \dots a_{24}$ be an orthonormal base of $\Lambda \otimes \mathbf{Z}_p$ corresponding to a set acted on by M_{24}, and the element g fixes at least one of the a_i's (as g is not of type 3C), say a_1. Then the conformal vector ω is $\sum a_i(1)a_i(1)/2$ which has nonzero inner product 1 with the element $a_1(1)a_1(1)$ $\mathrm{mod} p$. This proves 4.8.

The head representation $\hat{H}^0(g, V[1/2]_1)$ containing the conformal vector ω splits slightly differently depending on whether $p > 3$ or $p \leq 3$. If $p > 3$ then ω has norm $12 \bmod p$, which is nonzero so that $\hat{H}^0(g, V[1/2]_1)$ splits as the orthogonal direct sum of a 1-dimensional space spanned by ω and its orthogonal complement (and this splitting is obviously invariant under $C_M(g)$). If $p = 3$ and g is an element of type $3A$ then ω has norm $12 \equiv 0 \bmod 3$ so it is contained in its orthogonal complement, and $\hat{H}^0(g, V[1/2]_1)$ has a composition series of the form 1.781.1 (as a $C_M(g)/\langle g\rangle = Fi'_{24}$ module). The Atlas [C] states that the 781 dimensional module has an algebra structure mod 3, but this seems to be a mistake and the construction there only gives an algebra structure on 1.781.1 mod 3.

When g is in the class 3C then the vertex algebra $\hat{H}^0(g, V[1/2])$ does not have a conformal vector, and in fact not only is the image of ω equal to zero, but the whole degree 1 space $\hat{H}^0(g, V[1/2]_1)$ is zero. However we can turn $\hat{H}^0(g, V[1/2])$ into a better vertex algebra by "compressing" it. If we look at the series $q^{-1} + 248q^2 + 4124q^5 + \cdots$ we see that only every 3rd term of the graded space $\hat{H}^0(g, V[1/2])$ is nonzero. Hence we change the grading of the piece of degree $3n-1$ to n. We also change the vertex operator $v(x)$ of $v \in \hat{H}^0(g, V[1/2])$ to $v(x^{1/3})$. It is easy to check that this defines a new vertex algebra structure on $\hat{H}^0(g, V[1/2])$, (because if we are in characteristic 3 then $x - y = (x^{1/3} - y^{1/3})^3$), whose homogeneous degrees are the coefficients of $1 + 248q + 4124q^2 + \cdots$. The compression of the vertex algebra $\hat{H}^0(g, V[1/2])$ is probably isomorphic to the vertex algebra $V_{E_8}/3V_{E_8}$ (the vertex algebra of the E_8 lattice reduced mod 3) which is acted on by the finite group $E_8(\mathbf{F_3})$, because both vertex algebras have the same graded dimension and are both acted on by the Thompson group. (It is well known that the Thompson group $C_M(g)/\langle g\rangle$ is contained in $E_8(\mathbf{F_3})$.) Warning: the vertex algebra $V_{E_8}/3V_{E_8}$ can be lifted to characteristic 0, but the the action of the Thompson group does not lift to an action on the vertex algebra V_{E_8}.

5. The case $p = 2$.

In this section we will extend the proof of the modular moonshine conjectures (Corollary 4.8) to cover the case of the elements of type 2A in the monster, to obtain a vertex algebra over $\mathbf{F_2}$ acted on by the baby monster. The proof is similar to the cases for elements of odd order, except that there are several extra technical complications, and we have to use one assertion which we have not completely proved.

The theorems in this section depend on the following assumption about the monster vertex algebra. We have not rigorously verified this, but we sketch how its verification should go.

Assumption 5.1. *There is a $\mathbf{Z}[1/3]$-form $V[1/3]$ of the monster vertex algebra with a self dual bilinear form such that $V[1/3]$ can be written as a direct sum of $2.M_{12}.2$ modules each of which is isomorphic to a submodule of the $\mathbf{Z}[1/3]$-form $V_\Lambda[1/3]$ of V_Λ.*

We outline a possible proof of 5.1. (Roughly speaking, this outline would become a correct proof if Dong, Mason or Montague do not need to divide by any integer other than 3 in their constructions.) We obviously cannot use the FLM construction of the monster vertex algebra, which writes V as the sum of the eigenspaces of an element of type 2B, because this involves inverting 2 and gives a 2-divisible module whose cohomology vanishes. Instead we use the construction of the monster vertex algebra as a sum of eigenspaces of an element of type 3B, due independently to Dong and Mason [DM] and Montague [M]. This should produce a $\mathbf{Z}[1/3,\omega]$-form $V[1/3,\omega]$ of the monster vertex algebra as follows, where ω is a cube root of 1 satisfying $\omega^2+\omega+1=0$. We first note that modules over $\mathbf{Z}[1/3,\omega]$ can be written as the sums of eigenspaces of any group $\langle h\rangle$ of order 3 acting on them, because $a=\frac{a+h(a)+h^2(a)}{3}+\frac{a+\omega h(a)+\omega^2h^2(a)}{3}+\frac{a+\omega^2h(a)+\omega h^2(a)}{3}$. The vertex algebra $V[1/3,\omega]$ is a sum of 3 submodules V^0, V^1, and V^2, which are the eigenspaces of an element h of type 3B. The space V^0 is isomorphic to the subspace of $V_\Lambda[1/3,\omega]$ fixed by an element of order 3 coming from a fixed point free element of order 3 of $\mathrm{Aut}(\Lambda)$, and this defines the $\mathbf{Z}[1/3,\omega]$-form of V^0. The spaces V^i each split into the sum of 3 subspaces V^{ij} which are the eigenspaces of a group $(\mathbf{Z}/3\mathbf{Z})^2$ in the monster, and Dong and Mason and Montague show that there is a group $SL_2(\mathbf{F_3})$ acting transitively on the spaces V^{ij} for $(i,j)\neq(0,0)$. We use this group to transport the $\mathbf{Z}[1/3,\omega]$-form from V^{01} and V^{02} to V^{ij} for $i\neq 0$. This defines the $\mathbf{Z}[1/3,\omega]$-form on the monster vertex algebra (and it also has a self dual $\mathbf{Z}[1/3,\omega]$ bilinear form and a conformal vector, coming from the same structures on V_Λ).

We now reduce this $\mathbf{Z}[1/3,\omega]$-form to a $\mathbf{Z}[1/3]$-form. We have an operation of complex conjugation on V^0 coming from complex conjugation on $V_\Lambda\otimes\mathbf{Z}[1/3,\omega]$, and the action of $SL_2(\mathbf{F_3})$ can be used to transfer this to complex conjugation on all the spaces $V^{ij}\oplus V^{2i,2j}$, and hence to $V[1/3,\omega]$. This conjugation preserves the vertex algebra structure and commutes with the monster, and satisfies $\overline{\omega v}=\bar\omega\bar v$. Any element of $V[1/3,\omega]$ can be written uniquely in the form $a+\omega b$ with a and b fixed by conjugation, because finding a and b involves solving the 2 linear equations $v=a+b\omega$, $\bar v=a+\bar\omega v$, and there is a unique solution for a and b because the determinant of this system of equations is $\omega-\bar\omega$ which is a unit in $\mathbf{Z}[1/3,\omega]$. Hence if we define $V[1/3]$ to be the fixed points of the conjugation, we see that $V[1/3]\otimes\mathbf{Z}[1/3,\omega]=V[1/3,\omega]$. Hence $V[1/3]$ is a $\mathbf{Z}[1/3]$-form for the monster vertex algebra. This completes the arguments for assumption 5.1.

Theorem 5.2. *If we assume that 5.1 is correct then there is a vertex algebra defined over $\mathbf{F_2}$ acted on by the baby monster, such that the McKay-Thompson series of every element of the baby monster is a Hauptmodul. The vertex algebra has a conformal vector and a compatible self dual bilinear form, also invariant under the baby monster.*

Proof. We will only give details for parts of the argument that differ significantly from the proof of corollary 4.8. We choose an element $g\in M_{24}\subset\mathrm{Aut}(\Lambda)$ of order 2 and trace 8. (There is a unique conjugacy class of such elements in M_{24}.)

The first step is to prove that $\hat H^1(g,\Lambda)=\Lambda_{\langle g\rangle}/\mathrm{Ker}(N)=0$, which we do by direct calculation as follows. We can assume that g acts on Λ in the usual coordinates by acting as -1 on the first 8 coordinates and as $+1$ on the last 16. Then $\mathrm{Ker}(N)$ is the sublattice of Λ of vectors whose last 16 coordinates vanish. This lattice is a copy of the E_8 lattice with norms doubled (so it has 240 vectors of norm 4 and so on). It is generated by its norm 4 vectors and the centralizer of g acts transitively on these norm 4 vectors, so to prove that $\Lambda_{\langle g\rangle}=\mathrm{Ker}(N)$ we only need to prove that one of these norm 4 vectors is of the form $v-g(v)$ for some vector $v\in\Lambda$. We can do this by taking v to be the vector $(1^{23},-3)$. Therefore $\hat H^1(g,\Lambda)=0$.

From this it follows as in theorem 4.6 that $\hat H^1(\hat g,V_\Lambda)=0$, provided we show that g lifts to an element in $\mathrm{Aut}(\hat\Lambda)$ which we denote by $\hat g$, such that $\hat g$ also has order 2 and $\hat g$ fixes every element e^a of the twisted group ring of Λ corresponding to an element a of Λ fixed by g. (If g is of odd order the existence of a good element $\hat g$ is trivial, but for some elements of even order, for example those of trace 0, a lift with these properties does not exist.) Lemma 12.1 of [B92] says that such a lift $\hat g$ exists provided that $(v,g(v))$ is even for all elements $v\in\Lambda$, which follows because $(v,g(v))=((v-g(v),v-g(v))-(v,v)-(g(v),g(v)))/2$, and $(v,v)=(g(v),g(v))$ is even while $v-g(v)\in\mathrm{Ker}(N)$ has norm divisible by 4. Hence $\hat H^1(\hat g,V_\Lambda)=0$.

In particular any submodule of $V_\Lambda[1/3]$ invariant under $\hat g$ also has vanishing $\hat H^1$, so by assumption 5.1 $\hat H^1(\hat g,V[1/3])=0$. We can now follow the argument proving corollary 4.8 to construct a vertex algebra satisfying the conditions of theorem 5.2. This proves theorem 5.2.

Remark. In the proof of theorem 5.2 we should really have checked that the 2 vertex algebras constructed by Frenkel-Lepowsky-Meurman and by Dong-Mason-Montague are isomorphic as modules over the monster, so that the traces of elements of the monster are Hauptmoduls. Dong and Mason have announced [DM] that these two vertex algebras are indeed isomorphic as vertex algebras acted on by the monster. It would also be easy to show that they are isomorphic as modules over the monster (but not as vertex algebras) by using the results of [B92] to calculate the character of the Dong-Mason-Montague algebra.

It seems likely that $V[1/2]$ and $V[1/3]$ both come from a conjectural integral form V of the monster vertex algebra by tensoring with $\mathbf{Z}[1/2]$ or $\mathbf{Z}[1/3]$; see lemma 7.1.

If we look at the McKay-Thompson series for the element 2B of the monster we see that the coefficients are alternating, which suggests that $\hat{H}^0$ vanishes for half the homogeneous pieces of V, and $\hat{H}^1$ vanishes for the other half. The next theorem shows that this is indeed the case.

Theorem 5.3. *Assume that 5.1 is correct. If $\hat{g}$ is an element of type 2B in the monster, then $\hat{H}^0(\hat{g}, V[1/3]_n)$ vanishes if n is even, and $\hat{H}^1(\hat{g}, V[1/3]_n)$ vanishes if n is odd.*

Proof. By using the argument in the last few paragraphs of the proof of theorem 5.2 we see that it is sufficient to prove the same result for the cohomology with coefficients in V_Λ for a suitable element $\hat{g}$ of $\mathrm{Aut}(\hat{\Lambda})$. We will take g to be the automorphism -1 of Λ, and take its lift $\hat{g}$ in $\mathrm{Aut}(\hat{\Lambda})$ to be the element taking e^a to $(-1)^{(a,a)/2}(e^a)^{-1}$ in the group ring. It is easy to check that $\hat{g}$ is an automorphism of order 2. As a graded $\hat{g}$ module, V_Λ is the tensor product of the twisted group ring and the module $V_{\Lambda,0}$ as in theorem 4.6. The twisted group ring is a sum of infinitely many free modules over the group ring and one copy of $\mathbf{Z}$ (spanned by 1), so its 0'th cohomology group is $\mathbf{Z}/2\mathbf{Z}$, and its first cohomology vanishes. Hence $H^*(\hat{g}, V_\Lambda) = H^*(\hat{g}, V_{\Lambda,0})$. We let ω be the involution of $V_{\Lambda,0}$ that is the product of $\hat{g}$ and the involution acting as -1^n on the piece of degree n. As multiplying the action of $\hat{g}$ by -1 exchanges H^0 and H^1, we see that to prove theorem 5.3 we have to show that $H^1(\omega, V_{\Lambda,0}) = 0$. To do this it is sufficient to show that $V_{\Lambda,0}$ is a permutation module for ω.

We now complete the proof of theorem 5.3 by finding an explicit basis of $V_{\Lambda,0}$ described in terms of S-functions, on which ω acts as a permutation. If we choose a basis $a_1, \dots, a_{24}$ of Λ, then $V_{\Lambda,0}$ is the polynomial ring generated by the elements $h_{i,n} = e^{-a_i}D^{(n)}e^{a_i}$, $1 \le i \le 24$, $n \ge 1$. The element $\hat{g}$ takes $h_{i,n}$ to $e^{a_i}D^{(n)}e^{-a_i}$, so $\omega(h_{i,n}) = e_{i,n}$, where $e_{i,n} = (-1)^n e^{a_i}D^{(n)}e^{-a_i}$. From the relation

$$\sum_m D^{(m)}(e^{a_i})D^{(n-m)}(e^{-a_i}) = D^{(n)}(e^{a_i}e^{-a_i}) = 0$$

for $n \ge 1$ we find that

$$\sum_{0 \le m \le n} (-1)^m e_{i,m} h_{i,n-m} = 0$$

for $n \ge 1$, which recursively defines the $e_{i,n}$'s in terms of the $h_{i,n}$'s. If we identify the $h_{i,n}$'s with the n'th complete symmetric function (see [Mac], page 14) then the ring generated by the $h_{i,n}$'s for some fixed i is the ring of all symmetric functions. By the formulas 2.6' and 2.7 on page 14 of [Mac] we see that the $e_{i,n}$'s are then identified with the elementary symmetric functions, and ω with the canonical involution ω of [Mac]. The ring of all symmetric functions is spanned by the S-functions s_λ for permutations λ [Mac, p. 24, formulas 3.1 and 3.3], and the action of ω on the S-functions is given by

$$\omega(s_\lambda) = s_{\lambda'}$$

[Mac, p. 28, formula 3.8] where λ' is the conjugate partition of λ [Mac, p. 2]. Therefore the ring generated by the $h_{i,n}$'s for any fixed i is a permutation module for ω, and therefore so is $V_{\Lambda,0}$ because it is the tensor product of 24 permutation modules. This proves theorem 5.3.

Of course, as we are working in characteristic 2, there is really no difference between a vertex algebra and a vertex superalgebra, so the superalgebra associated to 2B can be considered as a vertex algebra with dimensions given by the coefficients of the series $q^{-1} + 276q + 2048q^2 + \cdots$. However it seems more natural to think of it as a superalgebra.

This superalgebra is acted on by the group $2^{24}.Co_1$. The next paragraph suggests that the 2^{24} may act trivially, so that we get an action of Co_1, but we have not proved this.

We can also ask if this superalgebra can be lifted to characteristic 0. It turns out that there is a vertex superalgebra (constructed below) with the right grading acted on by $\mathrm{Aut}(\Lambda)$. In fact this superalgebra has

2 different natural actions of Aut(Λ), one faithful, and one for which the center of Aut(Λ) acts trivially. Unfortunately we do not know of an integral form invariant under either action of Aut(Λ), but it seems reasonable to guess that both actions have invariant integral forms, and the reduction mod 2 of either integral form is the mod 2 vertex superalgebra above. (This requires that the 2^{24} acts trivially on this mod 2 vertex algebra.)

We can construct this superalgebra in characteristic 0 easily as the vertex superalgebra of the odd 12-dimensional unimodular lattice with no roots D_{12}, which is the set of vectors $(x_1, \ldots, x_{24})$ in $\mathbf{R}^{24}$ such that all the x_i's are integers or all are integers $+1/2$, and their sum is even. This vertex superalgebra is acted on by the spinor group $Spin_{12}(\mathbf{R})$. The group Aut(Λ) in $SO_{24}(\mathbf{R})$ can be lifted to the spin group as it has vanishing Schur multiplier, so we get an action of Aut(Λ) on the vertex algebra. The reason why we get two actions is that there are two conjugacy classes of embeddings of Aut(Λ) in $SO_{24}(\mathbf{R})$ (which are interchanged by a reflection). The spin group does not act faithfully because an element of order 2 in the center acts trivially, and it is not hard to check that for exactly one of the classes of embeddings of Aut(Λ) in $SO_{24}(\mathbf{R})$ the element $-1 \in \mathrm{Aut}(\Lambda)$ lifts to the element of $Spin_{24}(\mathbf{R})$ acting trivially.

The existence of these two actions of Aut(Λ) has the curious consequence that every second coefficient of $q^{-1} + 276q + 2048q^2 + \cdots$ is in a natural way the dimension of 2 different representations of Aut(Λ), in which the nontrivial element of the center acts as either $+1$ or -1. For example 2048 decomposes as either $1771 + 276 + 1$ or $2024 + 24$.

6. Example: the Held group.

We give some numerical tables to illustrate the case when g is an element of type 7A in the monster, with centralizer $\langle g\rangle \times He$. First we give the 7-modular character table of He (taken from [R88]), followed by the modular characters of the first few head characters of $\hat{H}^0(g, V[1/2])$ (which can be read off from [CN] table 4). The bottom line gives the corresponding conjugacy classes in the monster group (the one whose Hauptmodul is given by the coefficients of the head characters).

The values for the first 50 head characters can be extracted from the tables in [MS], by looking up the values of the head characters in the monster conjugacy classes listed in the last line. The paper [MS] also gives the decompositions of the first 50 head characters of the monster into irreducibles, which can be compared with the next table. (The top left corners of both tables are very similar.)

The next table gives the decomposition of the first few head characters H_i of $\hat{H}^0(g, V[1/2])$ into irreducible characters. The columns correspond to the irreducible characters arranged in order of their degrees (which are given in the first row). For example the 5th row means that the composition factors of the head representation H_2 are the representations of dimension 1, 50, and 153.

Notice that the multiplicities of nontrivial representations of small dimension have a tendency to start off with some of the values of the series $1, 1, 2, 3, 5, 7, \ldots$ which are the values $p(n)$ of the partition function. The same is true for the multiplicities of representations of the monster in the monster vertex algebra, and in that case it can be explained using the Virasoro algebra, and the fact that the Verma modules for the Virasoro algebra with $c = 24$, $h > 0$ are irreducible and have graded dimensions $1, 1, 2, 3, 5, 7, \ldots, p(n), \ldots$. (The irreducible factor of the Verma module with $c = 24$, $h = 0$ has pieces of dimension $p(n) - p(n-1) = 1, 0, 1, 1, 2, 2, 4, 4, 7, \ldots$, which more or less accounts for the initial multiplicities of the trivial character.) For our modular vertex algebras this explanation does not work so well, because the Verma modules are usually reducible over finite fields. We can get a small amount of information by examining how the Verma modules decompose, but this does not seem to be enough to account for why the numbers in the table above are so similar to the numbers we get when we look at the monster vertex algebra. On the other hand, if g has large prime order then the corresponding numbers do not seem to be similar to those for the monster; for example, if g has order 71 then the dimensions of the H_i's start off $1, 0, 1, 1, 1, \ldots$, which cannot be the dimensions corresponding to any representation of the Virasoro algebra in characteristic 0.

Silly question: why do the representations of dimension 1029 appear so late in the head characters?

7. Open problems and conjectures.

1. Can the information about modular representations be used to calculate the $|g|$-modular character tables of $C_M(g)$? The mod 7 character table of He has already been worked out in [R88], so the next simplest case is the mod 5 character table of the Harada-Norton group HN. For example, by cutting up the mod 5 vertex algebra of HN using the mod 5 Virasoro algebra we find that HN has representations over $\mathbf{F_5}$ of dimensions 1, 133, 626 and 2451 (which are probably irreducible). Unfortunately it seems to be difficult to get useful information like this from the later head representations, because we run into the problem that Verma modules over the Virasoro algebra mod p are not irreducible.
2. Does the monster vertex algebra have an integral form V such that each homogeneous piece is self dual under the natural bilinear form? It is easy to construct some monster invariant integral form by taking some integral form and taking the intersections of its conjugates under the action of the monster, but this will be far too small. The following lemma shows that we are quite close to constructing such an integral form.

Lemma 7.1. *Suppose that the spaces* $V[1/2] \otimes \mathbf{Z}[1/6]$ *and* $V[1/3] \otimes \mathbf{Z}[1/6]$ *are isomorphic as vertex algebras* *acted on by the monster. Then there exists an integral form of the monster vertex algebra with a compatible self dual integral bilinear form.*

Dong and Mason [DM] have announced that these two vertex algebras are isomorphic over the complex numbers, but their description of the proof (which has not appeared yet) sounds as if it might be hard to carry out over $\mathbf{Z}[1/6]$.

Proof. We denote $V[1/2]\otimes\mathbf{Z}[1/6]$ by $V[1/6]$, so we can assume that $V[1/6]$ contains $V[1/2]$ and $V[1/3]$ as subalgebras, and we define V to be $V[1/2]\cap V[1/3]$. It is obvious that V is a $\mathbf{Z}$-form of the monster vertex algebra, and we just have to check that the bilinear form on V is self dual. The embeddings of $V[1/2]$ and $V[1/3]$ into $V[1/6]$ preserve the conformal vector (as this is the only degree 2 vector ω fixed by the monster such that the operator ω_1 multiplies every vector by its degree), so the embeddings preserve the action of the Virasoro algebra. The bilinear forms are determined by the grading and vertex algebra structure and the action of the Virasoro algebra, so the embeddings also preserve the bilinear forms on all 4 algebras. If we look at the embedding of V into $V[1/2]$ we see that the bilinear form on V is self dual over $\mathbf{Z}_p$ for any odd prime p (as the bilinear form on $V[1/2]$ is self dual over $\mathbf{Z}[1/2]$), and similarly if we look at the embedding into $V[1/3]$ we see that the bilinear form on V is self dual over $\mathbf{Z}_p$ for any $p\neq 3$. Hence the symmetric bilinear form on V is self dual over all rings of p-adic integers, and is therefore self dual over $\mathbf{Z}$. This proves lemma 7.1.

It may be possible to prove that the vertex algebras $V[1/2]$ and $V[1/3]$ are isomorphic over $\mathbf{Z}[1/6]$ either by carrying out the proof suggested in [DM] over $\mathbf{Z}[1/6]$, or by constructing the monster vertex algebra as a sum of eigenspaces of an element of the monster of type 6B. This element corresponds to a fixed point free element of order 6 in $\mathrm{Aut}(\Lambda)$ (of trace 12) whose cube and square are the elements of orders 2 and 3 in $\mathrm{Aut}(\Lambda)$ used to construct $V[1/2]$ and $V[1/3]$.

The integral form V would give integral forms for all the homogeneous spaces V_n, and in particular would give an integral form on the Griess algebra V_1. This cannot be the same as the integral form constructed by Conway and Norton in [C85], because the one in [C85] contains the element $\omega/2$ (which is denoted by 1 there). It seems possible that Conway and Norton's integral form is spanned by $\omega/2$ together with the elements of V_1 which have integral inner product with $\omega/2$. Notice that the bilinear form used in [C85] is half the bilinear form on V_1.

3. Assume the integral form V exists. Is $\hat{H}^1(g,V)$ zero whenever g is an element of the monster whose Hauptmodul has no negative coefficients? (Theorem 4.7 shows this for some elements of odd order.) If the coefficients of the Hauptmodul for g alternate in sign, do the groups $\hat{H}^0(g,V_{2n})$ and $\hat{H}^1(g,V_{2n+1})$ vanish? (Theorem 5.3 proves this for elements of type 2B.)
4. What happens if g is an element of composite order? For example, if we look at the Hauptmodul for an element of type 4B we see that it starts off $q^{-1}+52q+834q^3+4760q^5$, and the coefficient 52 of q^1 is the dimension of the Lie algebra F_4, and the centralizer of an element of type 4B is of the form $(4\times F_4(\mathbf{F_2})).2$. This suggests there should be a modular vertex algebra corresponding to elements of type 4B, whose "compression" should be the reduction mod 2 or 4 of a vertex algebra for F_4 defined over $\mathbf{Z}$, in the same way that the compression of the vertex algebra for elements of type 3C is the reduction mod 3 of an algebra for E_8. (See the end of section 4.)
5. We can construct Lie algebras and superalgebras which have much the same relation to our modular vertex algebras as the monster Lie algebra [B92] has to the monster vertex algebra. We do this by using the $\mathbf{Z}_p$-forms of the monster vertex algebra to put $\mathbf{Z}_p$-forms on the monster Lie algebra (with a self dual symmetric invariant bilinear form), and then take the Tate cohomology of this $\mathbf{Z}_p$-form of the monster Lie algebra, which by the comments at the beginning of section 2 produces a Lie superalgebra. (Of course if we have a good integral form of the monster Lie algebra we can use this directly and not worry about $\mathbf{Z}_p$-forms.) The Lie algebras and superalgebras we get are similar to generalized Kac-Moody algebras, except that they are over fields of characteristic p rather than characteristic 0: they have a root system, a Cartan subalgebra, an invariant nonsingular symmetric bilinear form, a Cartan involution, and a $\mathbf{Z}$-grading with finite dimensional homogeneous pieces. Their structure as $C_M(g)$ modules can be described as follows: they have a $\mathbf{Z}^2$-grading, such that the piece of degree (m,n) is isomorphic to ${}^gV_{mn}$ if $(m,n)\neq(0,0)$, and the piece of degree $(0,0)$ (the Cartan subalgebra) is 2-dimensional and acted on trivially by $C_M(g)$. This suggests that there should be some sort of theory of "generalized Kac-Moody algebras mod$p$", which could be applied to study these algebras. For example, we could ask for the

Lie algebra homology groups of the positive degree subalgebras (which in characteristic 0 is equivalent to asking for the simple roots). Notice that many of these modular Lie algebras cannot be obtained by reducing some integral form of a generalized Kac-Moody algebra mod$p$, because the denominator formula shows that some of the simple roots would then have negative multiplicity.

6. The modules $\hat{H}^*(g, V[1/2])$ are acted on not just by the centralizer of g but by the normalizer $N_M(g)$ of g. What are the traces of elements of the normalizer of g that are not in the centralizer? It may be possible to do this by extending proposition 2.2 to the case when the subgroup $\langle g\rangle$ is only normal and not central. (Notice that if $\hat{H}^1(g, V[1/2])$ is nonzero then elements of the normalizer do not necessarily preserve the algebra structure on $\hat{H}^*(g, V[1/2])$.)
7. Give a complete proof of assertion 5.1.
8. Can the modular vertex algebras ${}^gV$ be lifted to characteristic 0 in some way? The answer to the strong form of this question is usually "no": it is easy to check that it is usually impossible to lift ${}^gV$ to a vertex algebra in characteristic 0 that is acted on by $C_M(g)$. However Queen [Q] found strong evidence that ${}^gV$ could be lifted to some $C_M(g)$ representation in characteristic 0 (which cannot carry an invariant vertex algebra structure). The representations that Queen found evidence for are now called twisted sectors. Perhaps these representations have some sort of "twisted" vertex algebra structure, where the vertex operators $a(z)$ have branch points of order p at the origin. It might be possible to use some sort of analogue of Witt vectors for vertex algebras to construct these. (But there is one serious obstruction to any canonical way of lifting some ${}^gV$'s to characteristic 0: the automorphism group in characteristic 0 is sometimes a *nonsplit* central extension of the automorphism group in characteristic p.) On the other hand we have seen (in the remarks at the end of sections 4 and 5) that if g is of type 3C or 2B then ${}^gV$ can probably be lifted to a vertex algebra in characteristic 0, which is not acted on by $C_M(g)$. Dong, Li and Mason [DLM] have recently made some progress on this question by constructing a twisted sector that is probably a lift to characteristic zero of the space ${}^gV$ when g is of type $2A$.
9. If $p = 3, 5, 7$, or 13 and g is an element of type pB in the monster corresponding to the group $\Gamma_0(p)$ then the group $C_M(g)/O_p(C_M(g))$ contains an element of order 2 in its center. We conjecture that this element of order 2 acts as $+1$ on $\hat{H}^0(g, V[1/2])$ and as -1 on $\hat{H}^1(g, V[1/2])$. This would imply that the graded modular characters of both $\hat{H}^0$ and $\hat{H}^1$ can be expressed as a linear combination of 2 Hauptmoduls. These are the only elements of prime order in the monster not already covered by theorems 4.7, 5.2, 5.3, and question 3 above, so an affirmative answer to this question and question 3 would mean that we would have a complete description of the modular characters of both $\hat{H}^0(g, V)$ and $\hat{H}^1(g, V)$ for all elements g of prime order in the monster.

In this paper we complete the proof of Ryba's modular moonshine conjectures [R] that was started in [B-R]. We do this by applying Hodge theory to the cohomology of the monster Lie algebra over the ring of p-adic integers in order to calculate the Tate cohomology groups of elements of the monster acting on the monster vertex algebra.

Contents.

1. Introduction.
Notation.
2. Representations of $\mathbf{Z}_p[G]$.
3. The $\mathbf{Z}[1/2]$-form of the monster Lie algebra.
4. The modular moonshine conjectures for $p \geq 13$.
5. Calculation of some cohomology groups.

7. Open problems and conjectures.

1. Introduction.

This paper is a continuation of the earlier paper [B-R] so we will only briefly recall results that are discussed there in more detail. In [B-R] we constructed a modular superalgebra for each element of prime order in the monster, and worked out the structure of this superalgebra for some elements in the monster. In this paper we work out the structure of this superalgebra for the remaining elements of prime order.

Ryba conjectured [R] that for each element of the monster of prime order p of type pA there is a vertex algebra ${}^gV$ defined over the finite field $\mathbf{F}_p$ and acted on by the centralizer $C_M(g)$ of g in the monster group M, with the property that the graded Brauer character $\mathrm{Tr}(h|{}^gV) = \sum_n \mathrm{Tr}(h|{}^gV_n)q^n$ is equal to the Hauptmodul $\mathrm{Tr}(gh|V) = \sum_n \mathrm{Tr}(g|V_n)q^n$ (where V is the graded vertex algebra acted on by the monster constructed by Frenkel, Lepowsky and Meurman [FLM]). In [B-R] the vertex superalgebra ${}^gV$ was defined for any element $g \in M$ of odd prime order to be the sum of the Tate cohomology groups $\hat{H}^0(g, V[1/2]) \oplus \hat{H}^1(g, V[1/2])$ for a suitable $\mathbf{Z}[1/2]$ form $V[1/2]$ of V, and it was shown that $\mathrm{Tr}(h|{}^gV) = \mathrm{Tr}(h|\hat{H}^0(g, V[1/2])) - \mathrm{Tr}(h|\hat{H}^1(g, V[1/2]))$ was equal to the Hauptmodul of $gh \in M$. Hence to prove the modular moonshine conjecture for an element g of type pA it is enough to prove that $\hat{H}^1(g, V[1/2]) = 0$. In [B-R] this was shown by explicit calculation for the elements of type pA for $p \leq 11$, using the fact that these elements commute with an element of type $2B$. For $p \geq 13$ this method does not work as these elements do not commute with an element of type $2B$. The first main theorem of this paper is theorem 4.1 which states that if g is an element of prime order $p \geq 13$ not of type $13B$ then $\hat{H}^1(g, V[1/2]) = 0$ (assuming a certain condition about the monster Lie algebra, whose proof should appear later). Hence Ryba's conjectures are proved for all elements of M of type pA. (Actually this is not quite correct, because the proof for $p = 2$ in [B-R] assumes an unproved technical hypothesis.) The proof we give fails for exactly the cases already proved in [B-R].

We can also ask what happens for the other elements of order less than 13. The cases of elements of types $2B$ or $3C$ are also treated in [B-R]: for type $3C$, $\hat{H}^1(g, V[1/2])$ is again zero, and for type $2B$, $\hat{H}^1(g, V[1/2])$ is zero in even degree and $\hat{H}^0(g, V[1/2])$ is zero in odd degree. This leaves the cases where g is of type $3B$, $5B$, $7B$, or $13B$, when the Tate cohomology groups $\hat{H}^0(g, V[1/2])$ and $\hat{H}^1(g, V[1/2])$ are usually both nonzero in each degree. In these cases the structure of the cohomology groups is determined

by our second main result, theorem 6.1, which states that the unique element σ of order 2 in the center of $C_M(g)/O_p(C_M(g))$ acts as 1 on $\hat{H}^0(g, V[1/2])$ and as -1 on $\hat{H}^1(g, V[1/2])$. This determines the modular characters of both cohomology groups because $\mathrm{Tr}(h|\hat{H}^0(g, V[1/2])) + \mathrm{Tr}(h|\hat{H}^1(g, V[1/2]))$ is then given by $\mathrm{Tr}(h\sigma|\hat{H}^0(g, V[1/2])) - \mathrm{Tr}(h\sigma|\hat{H}^1(g, V[1/2]))$ which is the Hauptmodul of the element $gh\sigma \in M$. Hence both $\mathrm{Tr}(h|\hat{H}^0(g, V[1/2]))$ and $\mathrm{Tr}(h|\hat{H}^1(g, V[1/2]))$ can be written explicitly as linear combinations of two Hauptmoduls for any p-regular element $h \in C_M(g)$. We get two new modular vertex superalgebras acted on by double covers of sporadic groups when g has type $3B$ or $5B$: a vertex superalgebra over $\mathbf{F}_3$ acted on by $2.Suz$, and a vertex superalgebra over $\mathbf{F}_5$ acted on by $2.HJ$. For elements of types $7B$ and $13B$ the vertex superalgebras we get are acted on by the double covers $2.A_7$ and $2.A_4$ of alternating groups.

In particular if the integral form V of the monster vertex algebra discussed in [B-R] exists and has the properties conjectured there then all the cohomology groups $\hat{H}^i(g, V)$ are now known for all elements g of prime order in M.

We now discuss the proofs of the two main theorems. We first quickly dispose of the second main theorem: if an element $g \in M$ of odd order commutes with an element of type $2B$ then it is easy to work out its action on the $\mathbf{Z}[1/2]$-form of the monster vertex algebra and hence the Tate cohomology groups $\hat{H}^*(g, V[1/2])$ can be calculated by brute force, which is what we do in sections 5 and 6 for the elements of types $3B$, $5B$, $7B$, and $13B$.

The elements g of prime order $p \geq 13$ do not commute with any elements of type $2B$ (except when g has type $13B$ or $23AB$) so we cannot use the method above. Instead we adapt the proof of the moonshine conjectures in [B]. By using a $\mathbf{Z}_p$-form of the monster Lie algebra rather than a $\mathbf{Q}$-form we can find some complicated relations between the coefficients of the series $\sum_n \mathrm{Tr}(h|\hat{H}^0(g, V[1/2]_n))q^n$ and $\sum_n \mathrm{Tr}(h|\hat{H}^1(g, V[1/2]_n))q^n$. The reason we get more information by using $\mathbf{Z}_p$-forms rather than $\mathbf{Q}_p$-forms is that the group ring $\mathbf{Z}_p[\mathbf{Z}/p\mathbf{Z}]$ has 3 indecomposable modules which are free over $\mathbf{Z}_p$, while the group ring $\mathbf{Q}_p[\mathbf{Z}/p\mathbf{Z}]$ only has 2 indecomposable modules which are free over $\mathbf{Q}_p$, and this extra indecomposable module provides the extra information. The relations between the coefficients we get are similar to the relations defining completely replicable functions, except that some of the relations defining completely replicable functions (about "$(2p-1)/p^2$" of them) are missing. If p is large (≥ 13) we show that these equations have only a finite number of solutions. We then use a computer to find all the solutions, and see that the only solutions imply that $\hat{H}^1(g, V[1/2]) = 0$ for all g of prime order at least 13 other than those of type $13B$. This proof could probably be made to work for some smaller values of p such as 7 and 11, but the difficulty of showing that there are no extra solutions for the equations of the coefficients increases rapidly as p decreases, because for smaller p there are more equations missing.

Y. Martin [Ma] has recently found a conceptual proof that any completely replicable function is a modular function. Cummins and Gannon [CG] have greatly generalized this result using different methods, and showed that the functions are Hauptmoduls. It seems possible that their methods could be extended to replace the computer calculations in section 4, although Cummins has told me that this would probably require adding in some "missing" relations corresponding to the case $(p, mn) \neq 0$ in proposition 3.4.

We summarize the results of this paper and of [B-R] about the vertex superalgebras ${}^gV$ for all elements g of prime order p in the monster. If g is of type pA, or pB for $p > 13$, or $3C$, then ${}^gV$ is just a vertex algebra and not a superalgebra. If $p \geq 13$ this is proved in this paper by an argument which works for any self dual form of the monster vertex algebra but which relies on computer calculations and on a so far unpublished argument about integral forms of the monster Lie algebra. For $p < 13$ (or $p = 23$) this is proved in [B-R] by calculating explicitly for a certain $\mathbf{Z}[1/2]$ form of the monster vertex algebra; this avoids computer calculations but only works for one particular form of the monster vertex algebra. Also, if $p = 2$ the calculation depends on an as yet unproved technical assumption about the Dong-Mason-Montague construction of the monster vertex algebra from an element of type $3B$ ([DM] or [M]). If g is of type pB for $2 \leq p \leq 13$ then the super part of ${}^gV$ does not vanish. If $p = 2$ then ${}^gV$ is calculated explicitly in [B-R] (again using the unproved technical assumption) and it turns out that its ordinary part vanishes in odd degrees and its super part vanishes in even degrees. If $3 \leq p \leq 13$ then ${}^gV$ is calculated in this paper, and we find that there is an element in $C_M(g)$ acting as -1 on the super part and as 1 on the ordinary part of ${}^gV$. In all cases we have explicitly described the modular characters of $C_M(g)$ acting on the ordinary or super part of any degree piece of ${}^gV$ in terms of the coefficients of certain Hauptmoduls.

Notation.

$[A]$	is the element of K represented by the module A.
A, B, C	G-modules.
A_n	The alternating group on n symbols.
Aut	The automorphism group of something.
$c_g^+(n)$	The n'th coefficient of the Hauptmodul of $g \in M$, equal to $\mathrm{Tr}(1\|^g V_n) = \dim(\hat{H}^0(g, V[1/2]_n)) - \dim(\hat{H}^1(g, V[1/2]_n))$.
$c_g^-(n)$	$\dim(\hat{H}^0(g, V[1/2]_n)) + \dim(\hat{H}^1(g, V[1/2]_n))$.
$c_{m,n}$	Defined in proposition 4.3.
$\mathbf{C}$	The complex numbers.
$C_M(g)$	The centralizer of g in the group M.
Co_1	Conway's largest sporadic simple group.
E	The positive subalgebra of the monster Lie algebra.
F	The negative subalgebra of the monster Lie algebra.
$\mathbf{F}_p$	The finite field with p elements.
f	A homomorphism from K to $\mathbf{Q}$ defined in lemma 2.3.
g	An element of G, usually of order p.
g_i	The element g^i of G, used when it is necessary to distinguish the multiplication in the group ring from some other multiplication.
$\langle g \rangle$	The group generated by g.
G	A group, often cyclic of prime order p and generated by g.
$h(A), h_n$	See section 5.
H	The Cartan subalgebra of the monster Lie algebra.
$\hat{H}^i(G, A)$	A Tate cohomology group of the finite group G with coefficients in the G-module A.
$\hat{H}^i(g, A)$	means $\hat{H}^i(\langle g \rangle, A)$, where $\langle g \rangle$ is the cyclic group generated by g.
$\hat{H}^*(g, A)$	The sum of the Tate cohomology groups $\hat{H}^0(g, A)$ and $\hat{H}^1(g, A)$, considered as a super module.
HJ	The Hall-Janko sporadic simple group (sometimes denoted J_2).
I	The indecomposable module of dimension $p-1$ over $\mathbf{Z}_p[G]$, isomorphic to the kernel of the natural map from $\mathbf{Z}_p[G]$ to $\mathbf{Z}_p$ and to the quotient $\mathbf{Z}_p[G]/N_G\mathbf{Z}_p$.
Im	The image of a map.
K	A ring which is a free $\mathbf{Q}$-module with a basis of 3 elements $[\mathbf{Z}_p] = 1$, $[\mathbf{Z}_p[G]]$, and $[I]$.
Ker	The kernel of a map.
$\Lambda, \hat{\Lambda}$	The Leech lattice and a double cover of the Leech lattice.
$\Lambda^n(A)$	The n'th exterior power of A.
$\Lambda^*(A)$	The exterior algebra $\oplus_n \Lambda^n(A)$ of A.
L	An even lattice.
$\mathbf{m}$	The monster Lie algebra.
M	The monster simple group.
N_G	The element $\sum_{g \in G} g$ of $\mathbf{Z}_p[G]$.
$O_p(G)$	The largest normal p-subgroup of the finite group G.
p	A prime, usually the order of g.
$\mathbf{Q}, \mathbf{Q}_p$	The rational numbers and the field of p-adic numbers.
ρ	The Weyl vector of the monster Lie algebra.
$\mathbf{R}$	The real numbers.
R_p	A finite extension of the p-adic integers.
$R(i)$	Defined just before lemma 3.2.
σ	An automorphism of type $2B$ in the monster or the automorphism -1 of the Leech lattice.
S_n	A symmetric group.
$S^n(A)$	The n'th symmetric power of A.
$S^*(A)$	The symmetric algebra $\oplus_n S^n(A)$ of A.
Suz	Suzuki's sporadic simple group.
Tr	$\mathrm{Tr}(g\|A)$ is the usual trace of g on a module A if A is a module over a ring of characteristic 0, and the Brauer trace if A is a module over a field of finite characteristic.
$V[1/n]$	A $\mathbf{Z}[1/n]$-form of the monster vertex algebra.

V_Λ *The integral form of the vertex algebra of* $\hat{\Lambda}$.
V_n *The degree* n *piece of* V.
V^n *An eigenspace of some group acting on* V.
${}^gV$ *A modular vertex algebra or superalgebra given by* $\hat{H}^*(g, V[1/n])$ *for some* n *coprime to* $|g|$.
$\mathbf{Z}$ *The integers.*
$\mathbf{Z}_p$ *The ring of* p*-adic integers.*
ω *A cube root of 1 or a conformal vector.*
Ω *The Laplace operator on* $\Lambda^*(E)$.

2. Representations of $\mathbf{Z}_p[G]$.

We give some auxiliary results about modules over $\mathbf{Z}_p[G]$ where G is a cyclic group generated by g of prime order p, and in particular calculate the exterior and symmetric algebras of all indecomposable modules. All modules will be free over $\mathbf{Z}_p$ and will be either finitely generated or $\mathbf{Z}$ graded with finitely generated pieces of each degree. All tensor products will be taken over $\mathbf{Z}_p$.

Recall from [B-R section 2] that there are 3 indecomposable modules over $\mathbf{Z}_p[G]$, which are $\mathbf{Z}_p$, the group ring $\mathbf{Z}_p[G]$, and the module I of $\mathbf{Z}_p[G]$ that is isomorphic to the kernel of the natural map from $\mathbf{Z}_p[G]$ to $\mathbf{Z}_p$ and to the quotient $\mathbf{Z}_p[G]/N_G\mathbf{Z}_p$ (where $N_G = 1+g+g^2+\cdots+g^{p-1}$). Their Tate cohomology groups are given by $\hat{H}^0(g,\mathbf{Z}_p) = \mathbf{Z}/p\mathbf{Z}$, $\hat{H}^1(g,\mathbf{Z}_p) = 0$, $\hat{H}^0(g,\mathbf{Z}_p[G]) = 0$, $\hat{H}^1(g,\mathbf{Z}_p[G]) = 0$, $\hat{H}^0(g,I) = 0$, and $\hat{H}^1(g,I) = \mathbf{Z}/p\mathbf{Z}$.

Lemma 2.1. *The tensor products of these modules are given as follows:*

$$\begin{aligned}\mathbf{Z}_p \otimes X &= X \ \textit{(for any } X\textit{)}\\ \mathbf{Z}_p[G] \otimes X &= \mathbf{Z}_p[G]^{\dim(X)} \ \textit{(the sum of } \dim(X) \textit{ copies of } \mathbf{Z}_p[G]\textit{)}\\ I \otimes I &= \mathbf{Z}_p[G]^{p-2} \oplus \mathbf{Z}_p.\end{aligned}$$

Proof. The case $\mathbf{Z}_p \otimes X$ is trivial. If X has a basis $x_1, \ldots, x_n$ then for any fixed i the elements $g^j \otimes g^j(x_i)$ ($0 \le j < p$) form a basis for a submodule of $\mathbf{Z}_p[G] \otimes X$ isomorphic to $\mathbf{Z}_p[G]$, and $\mathbf{Z}_p[G] \otimes X$ is the direct sum of these submodules for all i, which proves the result about $\mathbf{Z}_p[G] \otimes X$. For the case $I \otimes I$ we look at the cohomology sequence of the short exact sequence

$$0 \to I \otimes I \to I \otimes \mathbf{Z}_p[G] \to I \otimes \mathbf{Z}_p \to 0$$

to see that $\hat{H}^0(I \otimes I) = \mathbf{Z}/p\mathbf{Z}$ and $\hat{H}^1(I \otimes I) = 0$, which implies that $I \otimes I$ must be the sum of $\mathbf{Z}_p$ and some copies of $\mathbf{Z}_p[G]$. The number of copies can be worked out by looking at the dimensions of both sides. This proves lemma 2.1.

Corollary 2.2. *If* A *and* B *are* $\mathbf{Z}_p[G]$*-modules then* $\hat{H}^*(g, A \otimes B) = \hat{H}^*(g, A) \otimes \hat{H}^*(g, B)$.

Proof. Check each of the 9 cases when A and B are indecomposable modules using lemma 2.1. This proves corollary 2.2.

We form the ring K which is a free $\mathbf{Q}$-module with a basis of 3 elements $[\mathbf{Z}_p] = 1$, $[\mathbf{Z}_p[G]]$, and $[I]$ corresponding to the indecomposable modules of $\mathbf{Z}_p[G]$, whose addition and multiplication are those induced by tensor products and direct sums of modules. If A is a $\mathbf{Z}_p[G]$-module then we write $[A]$ for the element of K represented by A. Notice that this is not the same as the (tensor product with $\mathbf{Q}$ of the) Grothendieck ring of finitely generated projective $\mathbf{Z}_p[G]$ modules because we do not assume the relations given by nonsplit short exact sequences. The Grothendieck ring (tensored with $\mathbf{Q}$) is a quotient of our ring K by the ideal generated by $[\mathbf{Z}_p] + [I] - [\mathbf{Z}_p[G]]$.

Lemma 2.3. *There are exactly 3 ring homomorphisms* $\dim$, $\mathrm{Tr}(g|.)$, *and* f *from* K *to* $\mathbf{Q}$ *(which correspond to the 3 elements of the spectrum of* K*). They are given by*

1. $\dim([\mathbf{Z}_p]) = 1$, $\dim([\mathbf{Z}_p[G]]) = p$, $\dim([I]) = p-1$.
2. $\mathrm{Tr}(g|[\mathbf{Z}_p]) = 1$, $\mathrm{Tr}(g|[\mathbf{Z}_p[G]]) = 0$, $\mathrm{Tr}(g|[I]) = -1$.
3. $f([\mathbf{Z}_p]) = 1$, $f([\mathbf{Z}_p[G]]) = 0$, $f([I]) = 1$.

Proof. From corollary 2.2 we know that the products in the ring K are given by $[\mathbf{Z}_p[G]][\mathbf{Z}_p[G]] = p[\mathbf{Z}_p[G]]$, $[\mathbf{Z}_p[G]][I] = (p-1)[\mathbf{Z}_p[G]]$, and $[I][I] = (p-2)[\mathbf{Z}_p[G]] + 1$. Hence if $x \in \mathbf{Q}$ and $y \in \mathbf{Q}$ are the images of $[\mathbf{Z}_p[G]]$ and I under some homomorphism they must satisfy $x^2 = px$, $xy = (p-1)x$, and $y^2 = (p-2)x + 1$. The only solutions to these equations are $(x, y) = (p, p-1)$, $(0, 1)$, or $(0, -1)$. This proves lemma 2.3.

The first two homomorphisms in lemma 2.3 are the homomorphisms which factor through the Grothendieck ring and will not be very interesting to us. We can use them in place of f in the arguments in the rest of the paper, but this only leads to relations between the coefficients of $\sum_n \dim(V_n)q^n$ and $\sum_n \mathrm{Tr}(g|V_n)q^n$, which are essentially the relations already used in [B] to determine these functions. It is the third homomorphism f which detects the integral structure on $V[1/2]$ which will give us enough extra information to prove theorem 4.1.

In general, taking the trace of any fixed element of a group gives a homomorphism from a representation ring of a group to some field, and quite often (e.g., for the complex representation ring of a group) this gives a 1:1 correspondence between homomorphisms and (certain sorts of) conjugacy classes of the group. Lemma 2.3 gives an example of a homomorphism f not constructed in this way.

A permutation module is a module for G with a basis acted on by G. We recall from [B-R] that a module A is a permutation module if and only if $\hat{H}^1(g, A) = 0$, which in turn is equivalent to saying that A is a sum of copies of $\mathbf{Z}_p$ and $\mathbf{Z}_p[G]$.

Lemma 2.4. *If A is a permutation module over any ring for any finite group g then so are the symmetric powers $S^n(A)$. If all elements of G act on a basis of A as products of cycles of odd length then the exterior powers $\Lambda^n(A)$ are also permutation modules.*

Proof. For symmetric powers this is proved in [B-R]. For the proof for exterior powers, let $a_1, \ldots, a_n$ be a basis for A acted on by G. Then G acts on the set of all elements of the form $\pm a_{i_1} \wedge \cdots \wedge a_{i_n}$, which consists of all elements of a basis together with their negatives. If the action of G on the basis of A has the property that all elements of G are products of cycles of odd length, then there is no element of G that maps any element of the form $\pm a_{i_1} \wedge \cdots \wedge a_{i_n}$ to its negative. This means that we can find a G-invariant subset of these elements which forms a basis for $\Lambda^n(A)$. This proves lemma 2.4.

Lemma 2.5. *The exterior powers of indecomposable modules are given by*

$$\begin{aligned}
\Lambda^0(\mathbf{Z}_p) &= \mathbf{Z}_p \\
\Lambda^1(\mathbf{Z}_p) &= \mathbf{Z}_p \\
\Lambda^n(\mathbf{Z}_p) &= 0 \textit{ if } n \neq 0, 1 \\
\Lambda^0(\mathbf{Z}_p[G]) &= \mathbf{Z}_p \\
\Lambda^p(\mathbf{Z}_p[G]) &= \mathbf{Z}_p \textit{ if } p \textit{ is odd, and } I \textit{ if } p = 2 \\
\Lambda^n(\mathbf{Z}_p[G]) &= \mathbf{Z}_p[G]^{\binom{p-1}{n}} \textit{ if } 1 \leq n \leq p-1 \\
\Lambda^n(\mathbf{Z}_p[G]) &= 0 \textit{ if } n > p \\
\Lambda^n(I) &= \mathbf{Z}_p \oplus \mathbf{Z}_p[G]^{(\binom{p-1}{n}-1)/p} \textit{ if } n \textit{ is even and } 0 \leq n < p \\
\Lambda^n(I) &= I \oplus \mathbf{Z}_p[G]^{(\binom{p-1}{n}+1-p)/p} \textit{ if } n \textit{ is odd and } 0 \leq n < p \\
\Lambda^n(I) &= 0 \textit{ if } n \geq p
\end{aligned}$$

Proof. For the exterior powers of $\mathbf{Z}_p[G]$ with p odd we apply lemma 2.4 to see that all exterior powers are sums of $\mathbf{Z}_p$ and $\mathbf{Z}_p[G]$, and the exterior powers can then be identified by checking the dimension and the trace of g. The cohomology groups of the exterior powers of I can then be worked out by induction using the exact sequence

$$0 \to \Lambda^n(I) \to \Lambda^n(\mathbf{Z}_p[G]) \to \Lambda^{n-1}(I) \to 0.$$

The cohomology groups determine how many copies of $\mathbf{Z}_p$ and I occur in the decomposition into indecomposable modules, so we can work out the exterior powers of I from this. The remaining cases of lemma 2.5 are trivial, so this proves lemma 2.5.

These exterior powers induce operators on the ring K which we also denote by Λ^n. For example, we can use these operators to define Adams operations ψ^n on the ring K by

$$\sum_{n \in \mathbf{Z}} (-1)^n \Lambda^n([A]) q^n = \exp(-\sum_{n \in \mathbf{Z}} \psi^n([A]) q^n / n).$$

Corollary 2.6. *If p is odd then*

$$\sum_{n\in\mathbf{Z}}(-1)^n f([\Lambda^n(\mathbf{Z}_p)])q^n = 1-q$$

$$\sum_{n\in\mathbf{Z}}(-1)^n f([\Lambda^n(\mathbf{Z}_p[G])])q^n = 1-q^p$$

$$\sum_{n\in\mathbf{Z}}(-1)^n f([\Lambda^n(I)])q^n = (1+q^p)/(1+q)$$

Proof. This follows immediately from lemma 2.5 and lemma 2.3.

Lemma 2.7. *The symmetric powers of indecomposable modules are given by*

$$S^n(\mathbf{Z}_p) = \mathbf{Z}_p \text{ if } n \geq 0$$

$$S^n(\mathbf{Z}_p[G]) = \mathbf{Z}_p[G]^{\binom{p+n-1}{n}/p} \text{ if } (p,n)=1$$

$$S^n(\mathbf{Z}_p[G]) = \mathbf{Z}_p[G]^{(\binom{p+n-1}{n}-1)/p} \oplus \mathbf{Z}_p \text{ if } p|n$$

$$S^n(I) = \mathbf{Z}_p \oplus \mathbf{Z}_p[G]^{(\binom{p+n-2}{n}-1)/p} \text{ if } p|n$$

$$S^n(I) = I \oplus \mathbf{Z}_p[G]^{(\binom{p+n-2}{n}+1-p)/p} \text{ if } n \equiv 1 \bmod p$$

$$S^n(I) = \mathbf{Z}_p[G]^{(\binom{p+n-2}{n})/p} \text{ if } n \not\equiv 0,1 \bmod p$$

Proof. For symmetric powers of $\mathbf{Z}_p$ this is trivial and for symmetric powers of $\mathbf{Z}_p[G]$ it can be proved in the same way as in lemma 2.5. If $p=2$ then the case of I is easy to do as I is just one dimensional. For the case of I when p is odd we let N_G be the element $1+g+\cdots+g^{p-1} \in \mathbf{Z}_p[G]$ and consider the quotient of the symmetric algebra $S^*(\mathbf{Z}_p[G])$ by the ideal (N_G). This is the universal commutative algebra generated by $\mathbf{Z}_p[G]/N_G\mathbf{Z}_p$, so it is $S^*(\mathbf{Z}_p[G]/N_G\mathbf{Z}_p)$ which is isomorphic to $S^*(I)$ because $\mathbf{Z}_p[G]/N_G\mathbf{Z}_p$ is isomorphic to I. Therefore there is an exact sequence

$$0 \to S^{n-1}(\mathbf{Z}_p[G]) \to S^n(\mathbf{Z}_p[G]) \to S^n(I) \to 0.$$

Using the known cohomology groups of the symmetric powers of $\mathbf{Z}_p[G]$ and the exact sequence of cohomology groups of this exact sequence gives the cohomology groups of $S^n(I)$ and hence the number of times that $\mathbf{Z}_p$ and I occur in the decomposition of $S^n(I)$. This proves lemma 2.7.

Corollary 2.8. *The cohomology rings of the symmetric algebras of indecomposable modules are give as follows.*

$\hat{H}^*(S^*(\mathbf{Z}_p))$ is a polynomial algebra with one ordinary generator of degree 1.

$\hat{H}^*(S^*(\mathbf{Z}_p[G]))$ is a polynomial algebra with one ordinary generator of degree p.

$\hat{H}^*(S^*(I))$ is the tensor product of a polynomial algebra with one ordinary generator of degree p and an exterior algebra with one super generator of degree 1 if p is odd. (If p is even then $\hat{H}^*(S^*(I))$ is a polynomial algebra on one super generator of degree 1, but we do not need this case.)

Proof. This follows from the calculation of the symmetric powers in lemma 2.7. The product structure on the symmetric algebras can be worked out using the formula $d(ab) = (da)b \pm a(db)$ relating the cup product with the map d from $\hat{H}^i(C)$ to $\hat{H}^{i+1}(A)$ associated to the exact sequence $0 \to A \to B \to C \to 0$. This proves corollary 2.8.

Lemma 2.9. *Suppose that $A_{-1}=0, A_0,\ldots,A_n, A_{n+1}=0$ is a sequence of modules and we have maps d from A_i to A_{i+1} and d^* from A_{i+1} to A_i for all i such that $d^2=0$, $d^{*2}=0$, and $dd^*+d^*d=k$ for some fixed integer k coprime to p. Then*

$$[A_0]-[A_1]+[A_2]-\cdots+(-1)^n[A_n]=0.$$

Proof. The fact that k is a unit in $\mathbf{Z}_p$ implies that A_i is the direct sum $dd^*(A_i) \oplus d^*d(A_i)$ and that d is an isomorphism from $d^*d(A_i)$ to $dd^*(A_{i+1})$. The lemma follows from this because the sequence splits as the sum of these isomorphisms. (Notice that the relation between the $[A_i]$'s does not follow just from the exactness of d; for example, look at the short exact sequence $0 \to I \to \mathbf{Z}_p[G] \to \mathbf{Z}_p \to 0$. It is easy to check that in this case there is a map d^* with $d^{*2}=0$ and $dd^*+d^*d=p$, so the condition that $(k,p)=1$ is also necessary.) This proves lemma 2.9.

Lemma 2.10. *Suppose that A is a finitely generated free module over $\mathbf{Z}$ or $\mathbf{Z}_p$ with a symmetric self dual form $(,)$. Then this induces a symmetric self dual form (defined in the proof) on any exterior power $\Lambda^n(A)$.*

Proof. We define the bilinear form on $\Lambda^n(A)$ by

$$(a_1 \wedge \cdots \wedge a_n, b_1 \wedge \cdots \wedge b_n) = \sum_{\sigma \in S_n} \chi(\sigma)(a_1, b_{\sigma(1)}) \cdots (a_n, b_{\sigma(n)})$$

where $\chi(\sigma)$ is 1 or -1 depending on whether σ is an even or odd permutation. This obviously defines a symmetric bilinear form on $\Lambda^n(A)$ with values in $\mathbf{Z}$ or $\mathbf{Z}_p$, and we have to check it is unimodular. The determinant of $\Lambda^n(A)$ is equal to $a\det(A)^b$ for some constants a and b depending on n, but not on A. We can work out a by letting A be the lattice with a base of orthogonal elements $a_1, a_2, \ldots$ with norms ± 1, when we see that $\Lambda^n(A)$ also has an orthogonal base of elements $a_{i_1} \wedge a_{i_2} \cdots$ with $i_1 < i_2 < \cdots$ with norms ± 1, so both A and $\Lambda^n(A)$ have discriminant 1 and so $a = 1$. Hence if A is self dual then $\Lambda^n(A)$ has discriminant 1 and must also be self dual. This proves lemma 2.10. (It is easy to check that the constant b is equal to $\dim(\Lambda^n(A))/\dim(A)$ but we do not need this.)

The analogue of this lemma for symmetric powers is false. The proof breaks down because the element $a_{i_1}a_{i_2}\cdots$ with $i_1 \le i_2 \le \cdots$ does not have norm ± 1 if some of the i_j's are equal. In section 5 we will construct a graded algebra $h(A)$, such that the homogeneous components of $h(A)$ have self dual symmetric bilinear forms if A does, and $h(A) \otimes \mathbf{Q}_p$ is a sum of tensor products of symmetric powers of A.

The following corollary is purely for entertainment and is not used elsewhere in the paper.

Corollary 2.11. *There is a 28-dimensional self dual positive definite lattice with no roots, acted on by the orthogonal group $O_8^+(\mathbf{F}_2)$.*

Proof. By lemma 2.10 the lattice $\Lambda^2(E_8)$ is self dual, and is obviously acted on by the automorphism group of the E_8 lattice modulo -1, which is just $O_8^+(\mathbf{F}_2)$. It is easy to check that this lattice has no roots either by calculation or by observing that there is no suitable root lattice acted on by $O_8^+(\mathbf{F}_2)$. This proves lemma 2.11.

The lattice $\Lambda^2(E_8)$ has theta function

$$\sum_{\lambda \in \Lambda^2(E_8)} q^{\lambda^2/2} = 1 + 2240q^{3/2} + 98280q^{4/2} + 1790208q^{5/2} + 19138560q^{6/2} + \cdots.$$

The vectors of norm 3 are just the 2240 vectors generating one of the 1-dimensional sublattices of the form $\Lambda^2(L)$ where L is one of the 1120 sublattices of E_8 isomorphic to A_2.

3. The $\mathbf{Z}[1/2]$-form of the monster Lie algebra.

We find some relations between the dimensions of the Tate cohomology groups $\hat{H}^i(g, V[1/2])$ by studying the Lie algebra cohomology of the positive subalgebra of a $\mathbf{Z}_p$-form of the monster Lie algebra. In the next section we will use these relations to compute the cohomology groups in the case when g has order at least 13. We recall that $V[1/2]$ is the self dual $\mathbf{Z}[1/2]$-form of Frenkel, Lepowsky, and Meurman's monster vertex algebra [FLM] described in [B-R] (but the arguments in this section work for any self dual $\mathbf{Z}_p$-form of the monster vertex algebra).

This section should really be about the integral form of the monster Lie algebra, but this has not been constructed yet because of the lack of a construction of a self dual integral form of the monster vertex algebra. However, as we are only looking at the action of elements of odd order p in the monster and tensoring everything with $\mathbf{Z}_p$, a $\mathbf{Z}[1/2]$-form is just as good as an integral form.

We briefly recall some properties of the monster Lie algebra $\mathbf{m}$ from [B]. This is a $II_{1,1}$-graded Lie algebra acted on by the monster, where $II_{1,1}$ is the 2-dimensional even self dual Lorentzian lattice whose element (m, n) has norm $-2mn$. The piece of degree (m, n) of $\mathbf{m}$ is isomorphic to V_{mn} if $(m, n) \neq (0, 0)$ and to $\mathbf{R}^2$ if $(m, n) = (0, 0)$. The Lie algebra $\mathbf{m}$ is the sum of 3 subalgebras E, F, and H, where the Cartan subalgebra H is the piece of degree $(0, 0)$ of $\mathbf{m}$, E is the sum of all pieces of degree (m, n) of $\mathbf{m}$ for $m > 0$, and F is the sum of all pieces of degree (m, n) of $\mathbf{m}$ for $m < 0$.

The $\mathbf{Z}[1/2]$ form on V induces a self dual $\mathbf{Z}[1/2]$-form and hence a $\mathbf{Z}_p$-form on $\mathbf{m}$. From now on we will write $\mathbf{m}[1/2]$ for this $\mathbf{Z}[1/2]$-form. In the preprint version of this paper I implicitly assumed that the degree (m, n) piece of $\mathbf{m}$ was self dual and isomorphic as a module over the monster to V_{mn}. At the last moment I realized that this is not at all clear. The problem is that although the no-ghost theorem gives an isomorphism of both spaces tensored with $\mathbf{Q}$, and both spaces have $\mathbf{Z}[1/2]$-forms, there is no obvious reason why this isomorphism should map one $\mathbf{Z}[1/2]$ form to the other. (In fact for the fake monster Lie algebra the corresponding isomorphism does not preserve the integral forms.) Fortunately in this paper we only need the following weaker statement:

Assumption. *If $m < p$ then the degree (m, n) piece of $\mathbf{m} \otimes \mathbf{Z}_p$ is self dual under the natural bilinear form and isomorphic to $V_{mn} \otimes \mathbf{Z}_p$ as a $\mathbf{Z}_p$ module acted on by the monster.*

I believe I have a proof of this; if all goes well it will appear in a paper provisionally titled "The fake monster formal group". Until this paper appears all the statements in sections 3 and 4 and the modular moonshine conjectures for elements of type pA ($p \geq 13$) should have this assumption added as a hypothesis.

I do not know if the condition $m < p$ in the assumption above is necessary; if it is not, then this condition (usually added in parentheses) can be missed out of some of the following lemmas. It seems very likely that self duality still holds without it, but I am not so sure about the action of the monster being the same if both m and n are divisible by p.

The monster Lie algebra has a Weyl vector ρ, i.e., a vector in the root lattice $II_{1,1}$ such that $(\rho, \alpha) = -(\alpha, \alpha)/2$ for every simple root α. This follows from [B, theorem 7.2] which states that this simple roots are the vectors $(1, n)$ for $n \geq 0$ or $n = -1$, with multiplicities $c(n)$. Hence the Weyl vector is $\rho = (1, 0)$.

We recall some facts about Hodge theory applied to Lie algebra cohomology. The self dual symmetric bilinear form on the monster Lie algebra identifies E with the dual space of F, and using the Cartan involution which maps F to E we see that we have a symmetric bilinear form on the Lie algebra E (which is the restriction of the contravariant form of the monster Lie algebra to E) and in particular we can identify E with its dual. The Lie algebra cohomology is the cohomology of an operator d which maps each space $\Lambda^i(E)$ to $\Lambda^{i+1}(E)$. The adjoint of this operator is denoted by d^*, and we define the Laplace operator Ω by $\Omega = dd^* + d^*d$. As for any generalized Kac-Moody algebra with a Weyl vector, the action of the Laplace operator $\Omega = dd^* + d^*d$ on the degree $\alpha = (m, n) \in II_{1,1}$ piece of $\Lambda^*(E)$ is given by multiplication by $(\alpha, \alpha + 2\rho)/2 = (m - 1)n$. The Lie algebra cohomology group $H^i(E)$ of E can be identified with the zero eigenspace of Ω on $\Lambda^i(E)$. The Laplace operator restricted to $\Lambda^1(E) = E$ is half the partial Casimir operator Ω_0 defined in [K, section 2.5]; the extra factor of $1/2$ is necessary to make things work well over rings not containing $1/2$, but this is not important in this paper as we work over the ring of p-adic integers for odd p which always contains $1/2$.

Proposition 3.1. *The operators d and d^* act on the $\mathbf{Z}[1/2]$-form $\Lambda^*(E[1/2]) \subset \Lambda^*(E)$ of the exterior algebra (in all degrees (m, n) with $m < p$).*

Proof. The main point is that all homogeneous pieces of the $\mathbf{Z}[1/2]$-form of the exterior algebra are self dual under the contravariant bilinear form. This follows from lemma 2.10 and the fact that each homogeneous component is a finite sum of tensor products of exterior powers of the homogeneous components of $E[1/2]$. The result now follows from the fact that if d is a homomorphism of finite dimensional free $\mathbf{Z}[1/2]$-modules from A to B and A and B have self dual symmetric inner products then the adjoint d^* from B to A is well defined. This proves proposition 3.1.

We let $R(0)$ be the ring of formal Laurent series $K[[r, q]][1/r, 1/q]$ with coefficients in K, and we let $R(1)$ be the space of power series in $R(0)$ only involving monomials $r^m q^n$ with $p|mn$, and we let $R(2)$ be the subring of $R(0)$ of power series only involving powers of r^p and q^p. So we have the inclusions $R(2) \subset R(1) \subset R(0)$ and $R(1)$ is a module over $R(2)$ (but is not a ring itself). (We can also define $R(0)$, $R(1)$, and $R(2)$ for arbitrary generalized Kac-Moody algebras, in particular for the fake monster Lie algebra: $R(0)$ is a completion of the group ring of the root lattice, $R(1)$ is a subspace corresponding to the elements α of the root lattice with $p|(\alpha, \alpha)/2$, and $R(2)$ is the subring corresponding to p times the root lattice.) If A is a $\mathbf{Z}[1/2]$-module then we write $[A]$ for $[A \otimes_{\mathbf{Z}[1/2]} \mathbf{Z}_p]$.

Lemma 3.2. *If $(p, (m - 1)n) = 1$ (and $m < p$) then the piece of degree (m, n) of*

$$[\Lambda^*(E[1/2])] = [\Lambda^0(E[1/2])] - [\Lambda^1(E[1/2])] + [\Lambda^2(E[1/2])] - \cdots$$

vanishes. In other words

$$r^{-1}\Lambda^*(\sum_{m>0,n\in\mathbf{Z}} r^m q^n [V_{mn}])$$

lies in $R(1)$.

Proof. The Laplace operator $\Omega = dd^*+d^*d$ acts as multiplication by $(m-1)n$ on the degree (m,n) piece of $\Lambda^*(E[1/2])$, so the result follows from lemma 2.9 if we let A_i be the degree (m,n) piece of $\Lambda^i(E[1/2])$. This proves lemma 3.2.

Lemma 3.3. *If* A *is a* $\mathbf{Z}_p[G]$*-module with* $\mathrm{Tr}(g|A) = c^+$, $f([A]) = c^-$, *(and* $m < p$*) then*

$$f(\Lambda^*(r^m q^n A)) = (1 - r^m q^n)^{(c^+ + c^-)/2}(1 + r^m q^n)^{(c^+ - c^-)/2}U$$

where U *is a unit of the ring* $R(2)$.

Proof. It is sufficient to prove this for an indecomposable module A because both sides are multiplicative. We just check each of the three possibilities for A using lemma 2.6.

If $A = \mathbf{Z}_p$ then $c^+ = c^- = 1$ and $f(\Lambda^*(r^m q^n [\mathbf{Z}_p])) = 1 - r^m q^n$, so lemma 3.3 is true in this case.

If $A = \mathbf{Z}_p[G]$ then $c^+ = c^- = 0$ and $f(\Lambda^*(r^m q^n [\mathbf{Z}_p[G]])) = 1 - r^{mp}q^{np}$ which is a unit in $R(2)$, so lemma 3.3 is true in this case.

If $A = I$ then $c^+ = -1$, $c^- = 1$ and

$$f(\Lambda^*(r^m q^n [I])) = (1 + r^{mp}q^{np})/(1 + r^m q^n) = U(1 + r^m q^n)^{-1},$$

so lemma 3.3 is also true in this case. This proves lemma 3.3.

We define integers $c_g^+(n)$ and $c_g^-(n)$ by

$$\begin{aligned} c_g^+(n) &= \mathrm{Tr}(g|V_n) = \dim(\hat{H}^0(g, V[1/2]_n)) - \dim(\hat{H}^1(g, V[1/2]_n)) \\ c_g^-(n) &= f(V[1/2]_n) = \dim(\hat{H}^0(g, V[1/2]_n)) + \dim(\hat{H}^1(g, V[1/2]_n)). \end{aligned}$$

We use the numbers $c_g^+(n)$ and $c_g^-(n)$ rather than the apparently simpler numbers $\dim(\hat{H}^0(g, V[1/2]_n))$ and $\dim(\hat{H}^1(g, V[1/2]_n))$ because they turn out to be coefficients of Hauptmoduls, and because $c_g^+(n)$ is already known.

Proposition 3.4. *If* $(p, mn) = 1$ *(and* $m < p$*) then the coefficient of* $r^m q^n$ *in*

$$r^{-1}\prod_{m>0,n\in\mathbf{Z}} (1 - r^m q^n)^{(c_g^-(mn)+c_g^+(mn))/2}(1 + r^m q^n)^{(c_g^+(mn)-c_g^-(mn))/2}$$

vanishes. In other words this power series lies in $R(1)$.

Proof. We apply the homomorphism f to the expression in lemma 3.2 and use lemma 3.3. We find that the expression in this proposition is equal to an element of $R(1)$ times a unit in $R(2)$, and is therefore still an element of $R(1)$. Therefore its coefficients of $r^m q^n$ vanish unless $p|mn$. This proves proposition 3.4.

Proposition 3.4 can be generalized in the obvious way to any generalized Kac-Moody algebra which has a self dual $\mathbf{Z}_p$-form, a Weyl vector, and an integral root lattice.

We can also ask whether or not the coefficients of $r^m q^n$ in proposition 3.4 vanish when $p|mn$. Some numerical calculations suggest that they usually do not.

4. The modular moonshine conjectures for $p \geq 13$.

In this section we prove the following theorem, which completes the proof of the modular moonshine conjectures of [R section 6] (apart from a small technicality in the case $p = 2$.)

Theorem 4.1. *If $g \in M$ is an element of prime order $p \geq 17$ or an element of type $13A$ then $\hat{H}^1(g, V[1/2]) = 0$.*

This implies that ${}^gV = \hat{H}^0(g, V[1/2]) = \hat{H}^*(g, V[1/2])$ is a vertex algebra whose modular character is given by Hauptmoduls, and whose homogeneous components have the characters of [R definition 2].

The proof of this theorem will occupy the rest of this section. We have to show that the numbers $c_g^-(n)$ of proposition 3.4 are equal to the numbers $c_g^+(n)$, because the difference is twice the dimension of $\hat{H}^1(g, V[1/2]_n)$. We start by summarizing what we know about these numbers.

Lemma 4.2.

1. *The numbers $c_g^-(n)$ and $c_g^+(n)$ satisfy the relations given in proposition 3.4.*
2. *The numbers $c_g^-(n)$ are integers, with $c_g^-(n) \equiv c_g^+(n) \bmod 2$.*
3. *$c_g^-(n) \geq |c_g^+(n)|$ and $(p-2)c_g^+(n) + pc_g^-(n) \leq 2c_1^+(n)$, (where $c_1^+(n)$ is the coefficient of q^n in the elliptic modular function).*
4. *The numbers $c_g^+(n)$ are the coefficients of the Hauptmodul of the element $g \in M$.*

Proof. These properties follow easily from proposition 3.4 together with the fact that $\mathbf{Z}_p \otimes V_n$ has dimension $c_1^+(n)$ and is the sum of $(c_g^-(n) + c_g^+(n))/2$ copies of $\mathbf{Z}_p$, $(c_g^-(n) - c_g^+(n))/2$ copies of I, and some copies of $\mathbf{Z}_p[G]$. This proves lemma 4.2.

We will prove theorem 4.1 by showing that if g satisfies the conditions of theorem 4.1 then the conditions 1 to 4 in lemma 4.2 imply that $c_g^-(n) = c_g^+(n)$. We find a finite set of possible solutions of conditions 1, 2, and 4 of lemma 4.2, and find that for each p only one of these satisfies the condition 3. (There are often several solutions not satisfying condition 3.) The proof is just a long messy calculation and the reader should not waste time looking at it.

We first put the relations into a more convenient form.

Proposition 4.3. *There are integers $c_{m,n}$ defined for $m, n > 0$ (and $m < p$) with the following properties.*

1. $$-\log\left(1 + \sum_{m>0,n>0} c_{m,n} r^m q^n\right) \equiv \sum_{m>0,n>0} \sum_{d|(m,n)} \frac{c_g^{(-)^d}(mn/d^2)}{d} r^m q^n \bmod r^p$$
2. *If $(p, mn) = 1$ then $c_{m+1,n} = c_{m,n+1}$.*

Proof. This follows from proposition 3.4 if we multiply both sides by $(r-q)/rq$ and then take the logarithm of both sides. This proves proposition 4.3.

Lemma 4.4. *If $p > 13$ then the values of $c_g^-(n)$ for $n \leq 21$, $c_g^-(2n)$ for $2n \leq 32$, and $c_g^-(36)$ and $c_g^-(45)$ are given by polynomials in the numbers $c_g^-(i)$ for $i = 1, 2, 4, 5$ with coefficients in $\mathbf{Z}_3$.*

Proof. We can evaluate the elements $c(n), n \leq 21$ and $c(2n), n \leq 16$ using the argument for cases 1 and 2 of lemma 4.7 below. We can evaluate $c(36)$ by looking at the coefficient of r^4q^9 in proposition 4.3 and using the fact that we know $c_{m,n}$ for $m \leq 3$, $n \leq 8$. Similarly we can evaluate $c(45)$ by looking at the coefficient of r^5q^9. Notice that the term $(\sum_{m,n} c_{m,n} r^m q^n)^3/3$ has 3's only in the denominators of coefficients of $r^m q^n$ when $3|m$ and $3|n$, so we do not get problems from this for the coefficients of r^4q^9 and r^5q^9 (but we do get problems from this if we try to work out $c_g^-(27)$ using the same method). This proves lemma 4.4.

If $p = 13$ we run into trouble when we try to determine $c_g^-(26)$; this is why the argument in lemma 4.4 does not work in this case. Also the argument breaks down if we try to work out $c(27)$, because when we look at the coefficient of r^3q^9 we get an extra term $c_g^-(3)/3$ which does not have coefficients in $\mathbf{Z}_3$. This is why we use the coefficients $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $c_g^-(5)$ rather than $c_g^-(1)$, $c_g^-(2)$, $c_g^-(3)$, and $c_g^-(5)$.

Lemma 4.4 is the reason why our arguments do not work for $p < 13$ (and do not work so smoothly for $p = 13$). As p gets smaller we have fewer relations to work with and it gets more difficult to determine all coefficients in terms of the $c_g^-(m)$'s for small m. It is probably possible to extend lemma 4.4 to cover some smaller primes with a lot of effort. Fortunately it is not necessary to do the cases $p < 13$ because these cases have already been done by explicit calculations in [B-R].

Lemma 4.5. *If $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $c_g^-(5)$ are known mod 3^n for some $n \geq 1$, and $p > 13$, and $(c_g^-(1), 3) = 1$ if $p = 13$, then these values of $c_g^-(m)$ are determined mod 3^{n+1}.*

Proof. By lemma 4.4 we see that we can determine the values mod 3^n of $c_g^-(n)$ for $n \leq 16$, $c_g^-(2n)$ for $2n \leq 32$, and $c_g^-(36)$ and $c_g^-(45)$.

But now if we look at the coefficient of r^3q^{3m} of 3.4 with $m = 1, 2, 4$, or 5, we see that $c_g^-(9m) + c_g^+(2m)/2 + c_g^-(m)/3 = c_g^-(m)^3/3+$ (some polynomial in known $c_g^-(i)$'s with coefficients that are 3-adic integers). But $c_g^-(m)^3/3$ mod 3^n depends only on $c_g^-(m)$ mod 3^n if $n \geq 1$, so we can determine $c_g^-(m)/3$ mod 3^n and hence $c_g^-(m)$ mod 3^{n+1}. This proves lemma 4.5.

This lemma is the reason that we use 3-adic rather than 2-adic approximation. If we try to prove the lemma above for 2^{n+1} instead of 3^{n+1}, all we find is that we can determine the $c_g^+(m)$'s mod 2^{n+1}, which is useless because we already know these numbers.

Proposition 4.6. *If the numbers $c_g^-(n)$ satisfy the conditions 1, 2, and 4 of lemma 4.2 then the numbers $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $c_g^-(5)$ are congruent mod 3^{29} to the coefficients of q, q^2, q^4, and q^5 of one of the following power series. (The second column is a genus zero group whose Hauptmodul appears to be the function with coefficients $c_g^-(n)$. This has not been checked rigorously as it is not necessary for the proof of theorem 4.1.)*

$p = 71$	$\Gamma_0(71)+$	q^{-1}	$+q$	$+q^2$	$+q^3$	$+q^4$	$+2q^5$	$+\cdots$
$p = 59$	$\Gamma_0(59)+$	q^{-1}	$+q$	$+q^2$	$+2q^3$	$+2q^4$	$+3q^5$	$+\cdots$
$p = 47$	$\Gamma_0(47)+$	q^{-1}	$+q$	$+2q^2$	$+3q^3$	$+3q^4$	$+5q^5$	$+\cdots$
$p = 47$	$\Gamma_0(94)+$	q^{-1}	$+q$		$+q^3$	$+q^4$	$+q^5$	$+\cdots$
$p = 41$	$\Gamma_0(41)+$	q^{-1}	$+2q$	$+2q^2$	$+3q^3$	$+4q^4$	$+7q^5$	$+\cdots$
$p = 41$	$\Gamma_0(82\|2)+$	q^{-1}			$+q^3$		$+q^5$	$+\cdots$
$p = 31$	$\Gamma_0(31)+$	q^{-1}	$+3q$	$+3q^2$	$+6q^3$	$+9q^4$	$+13q^5$	$+\cdots$
$p = 31$	$\Gamma_0(62)+$	q^{-1}	$+q$	$+q^2$	$+2q^3$	$+q^4$	$+3q^5$	$+\cdots$
$p = 29$	$\Gamma_0(29)+$	q^{-1}	$+3q$	$+4q^2$	$+7q^3$	$+10q^4$	$+17q^5$	$+\cdots$
$p = 29$	$\Gamma_0(58\|2)+$	q^{-1}	$+q$		$+q^3$		$+q^5$	$+\cdots$
$p = 23$	$\Gamma_0(23)+$	q^{-1}	$+4q$	$+7q^2$	$+13q^3$	$+19q^4$	$+33q^5$	$+\cdots$
$p = 23$	$\Gamma_0(46) + 23$	q^{-1}		$-q^2$	$+q^3$	$-q^4$	$+q^5$	$+\cdots$
$p = 23$	$\Gamma_0(46)+$	q^{-1}	$+2q$	$+q^2$	$+3q^3$	$+3q^4$	$+5q^5$	$+\cdots$
$p = 19$	$\Gamma_0(19)+$	q^{-1}	$+6q$	$+10q^2$	$+21q^3$	$+36q^4$	$+61q^5$	$+\cdots$
$p = 19$	$\Gamma_0(38)+$	q^{-1}	$+2q$	$+2q^2$	$+5q^3$	$+4q^4$	$+9q^5$	$+\cdots$
$p = 19$	$\Gamma_0(38\|2)+$	q^{-1}	$+2q$		$+q^3$		$+3q^5$	$+\cdots$
$p = 17$	$\Gamma_0(17)+$	q^{-1}	$+7q$	$+14q^2$	$+29q^3$	$+50q^4$	$+92q^5$	$+\cdots$
$p = 17$	$\Gamma_0(34)+$	q^{-1}	$+3q$	$+2q^2$	$+5q^3$	$+6q^4$	$+12q^5$	$+\cdots$
$p = 17$	$\Gamma_0(34\|2)+$	q^{-1}	$+q$		$+3q^3$		$+4q^5$	$+\cdots$
$p = 13$	$\Gamma_0(13)+$	q^{-1}	$+12q$	$+28q^2$	$+66q^3$	$+132q^4$	$+258q^5$	$+\cdots$
$p = 13$	$\Gamma_0(26)+$	q^{-1}	$+4q$	$+4q^2$	$+10q^3$	$+12q^4$	$+26q^5$	$+\cdots$
$p = 13$	$\Gamma_0(26\|2)+$	q^{-1}	$+2q$		$+4q^3$		$+6q^5$	$+\cdots$

It is also possible (but unlikely) that there are other solutions for $p = 13$ for which $c_g^-(1)$ does not satisfy the inequalities $0 \leq c_g^-(1) < 3^{10}$.

Proof. For each prime p we use a computer to test all 81 possibilities for $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $c_g^-(5)$ mod 3. If $p > 13$ then we can calculate the p-adic expansion of all the coefficients $c_g^-(n)$ recursively using lemma 4.5 above, and we reach a contradiction by looking at coefficients of proposition 4.3 except in the cases above. For $p = 13$ this does not quite work as we have not shown the values mod 3^n determine those mod 3^{n+1}, so we can adopt the crude procedure of just testing all 3^4 possibilities for the $c_g^-(i)$'s mod 3^{n+1} for each solution mod 3^n we have found, and checking to see which of them leads to contradictions. There were some cases for $p = 13$ where this did not lead to a contradiction but did at least lead to the conclusion that $c_g^-(1) < 0$ or $c_g^-(1) \geq 3^{10}$. (If $c_g^-(1)$ is not divisible by 3 then even when $p = 13$ the numbers $c_g^-(i)$ mod 3^n determine the numbers $c_g^-(n)$ mod 3^{n+1}. When $c_g^-(1)$ was divisible by 3, there were several cases where the coefficient $c_g^-(5)$ was not determined mod 3^{n+1} by the identities used by the computer program. However in all the cases looked at by the computer with $3|c_g^-(1)$, the values of $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $3c_g^-(5)$ mod 3^n uniquely determined their values mod 3^{n+1}.) This proves proposition 4.6, at least if one believes the computer calculations. (Anyone who does not like computer calculations in a proof is welcome to redo the calculations by hand.)

Lemma 4.7. *If the coefficients $c_g^-(1)$, $c_g^-(2)$, $c_g^-(4)$, and $c_g^-(5)$ are equal to the coefficients $c_g^+(1)$, $c_g^+(2)$, $c_g^+(4)$, and $c_g^+(5)$ for g an element of prime order $p > 13$ or an element of type $13A$ then all the coefficients are determined by the relations of proposition 3.4.*

Proof. This proof is just a long case by case check using induction. We will repeatedly use the fact that the coefficients of $r^m q^n$ of both sides of proposition 4.3 are equal.

Case 1. $c_g^-(2n)$ for $2n \not\equiv 0 \bmod p$. By looking at the coefficient of r^2q^n and using the fact that $c_{2,n} = c_{1,n+1}$ (as $(p,n) = 1$) we see that $c_g^-(2n)$ can be written as a polynomial in $c(n+1)$ and $c(i)$ for $1 \leq i < n$.

Case 2. $c_g^-(2n+1)$ for $2n+1 \not\equiv \pm 1 \bmod p$. By looking at the coefficient of r^2q^{2n} we can express $c_g^-(2n+1)$ in terms of $c_g^-(4n)$ and known quantities. But $c_g^-(4n)$ can be evaluated by looking at the coefficient of r^4q^n and using the fact that $c_{4,n} = c_{3,n+1} = c_{2,n+2}$ (as $2n+1 \not\equiv \pm 1 \bmod p$).

The recursion formulas given by cases 1 or 2 can be written out explicitly and are given in [B, (9.1)]. In that paper they are sufficient to determine all coefficients because the analogues of the relations in proposition 3.4 hold whenever $mn \neq 0$.

The remaining cases of the proof are unusually tedious so we only sketch them briefly.

Case 3. $c_g^-(2n)$ for $2n \equiv 0 \bmod p$, n odd. We can express this in terms of $c_{2,n} = c_{3,n-1}$, which we can evaluate by calculating $c_g^-(3(n-1)) = c_g^-(2(3(n-1)/2))$ using case 1.

For the rest of the proof it is convenient to evaluate the cluster of elements $c_g^-(2pn-1)$, $c_g^-(2pn+1)$, and $c_g^-(4pn)$, simultaneously. (These are the only cases left to do.)

Case 4. $2np \equiv 2 \bmod 3$. We evaluate $c_g^-(2np+1)$ in terms of $c_{3,(2np+1)/3}$. We evaluate $c_g^-(2np-1)$ by expression $c_g^-(2np-1)c(2)$ in terms of $c_{2,2np+1}$ and evaluating the latter by comparing it with $c_{3,2(2np+1)/3}$. We evaluate $c_g^-(4np)$ by expressing $c_{3,2np+2}$ in terms of $c_g^-(2)c_{2,2np}$ and evaluating the latter by comparing it with $c_{2,3np+3}$.

Case 5. $2np \equiv 1 \bmod 3$. We evaluate $c_g^-(2np-1)$ in terms of $c_{3,(2np-1)/3}$. We evaluate $c_{1,2np+5}$ by using $c_{3,(2np+5)/3}$ and then evaluate in turn $c_{2,2np+4} = c_{1,2np+5}$, $c_g^-(1)c_{1,2np+3}$ (using the coefficient of r^2q^{2np+4}), $c_{2,2np+3} = c_{1,2np+3}$, $c_g^-(1)c_{1,2np+1}$ which gives us the value of $c_{1,2np+1}$. We evaluate $c_{2,2np}$ as in case 4.

Case 6. $2np \equiv 0 \bmod 3$. By looking at $c_{2,2np+2}$ and $c_{2,2np+3}$ we can find expressions for the linear combinations $c_g^-(1)c_g^-(2np+1) + c_g^-(3)c_g^-(2np-1)$ and $c_g^-(2)c_g^-(2np+1) + c_g^-(4)c_g^-(2np-1)$. If $p \neq 59$ or 71 then these two linear equations are independent so we can solve for $c_g^-(2np+1)$ and $c_g^-(2np-1)$, and then find $c_{2,2np}$ as in case 4. If $p = 59$ or 71 then an even more tedious argument using $c_{2,2np+2}$, $c_{3,2np+2}$, and $c_{3,2np+3}$ produces 3 independent linear relations between $c_g^-(2pn-1)$, $c_g^-(2pn+1)$, and $c_g^-(4pn)$, so we can solve for them.

This proves lemma 4.7.

We can now complete the proof of theorem 4.1. If we look at the possible solutions for the coefficients $c_g^-(n)$ given by proposition 4.6, we see that all the solutions except those congruent mod 3^{29} to the Hauptmoduls of the elements $g \in M$ are ruled out by the inequalities of lemma 4.2. As $3^{29} > c_1^+(i) > c_g^-(i) \geq 0$ for $i \leq 5$ we see that $c_g^+(i) = c_g^-(i)$ for $i \leq 5$. The coefficients $c_g^+(n)$ also satisfy the identities of proposition 4.3 satisfied by the $c_g^-(n)$'s; for example, this follows easily from the identity

$$\sum_{n\in\mathbf{Z}} c_g^+(n)r^n - \sum_{n\in\mathbf{Z}} c_g^+(n)q^n = r^{-1} \prod_{m>0, n\in\mathbf{Z}} (1 - r^m q^n)^{c_g^+(mn)} (1 - r^{pm}q^{pn})^{c_g^+(pmn)}$$

[B, page 434]. Therefore $c_g^-(n) = c_g^+(n)$ for all n by lemma 4.7 because they both have the same values for $n \leq 5$ and both satisfy the same recursion relations given in proposition 3.4. This proves theorem 4.1.

5. Calculation of some cohomology groups.

In this section we calculate the Tate cohomology groups of some spaces that appear in the construction of the monster vertex algebra. In the next section we will use these calculations to find the Tate cohomology $\hat{H}^*(g, V[1/2])$ for elements g of types $3B$, $5B$, $7B$ and $13B$.

We will write $g_0, g_1, \dots, g_{p-1}$ for the elements $1, g, \dots, g^{p-1}$ of the group ring $\mathbf{Z}_p[G]$ to avoid confusing the group ring multiplication with the multiplication in other rings containing it.

Suppose that A is a free $\mathbf{Z}_p$-module. We write $h(A)$ for the $\mathbf{Z}$-graded $\mathbf{Z}_p$-algebra generated by elements $h_n(a)$ of degree n for $a \in A$, $n \geq 0$ with the relations

1. $h_n(\lambda a) = \lambda^n h_n(a)$ if $\lambda \in \mathbf{Z}_p$.
2. $h_0(a) = 1$, $h_n(a) = 0$ if $n < 0$.
3. $h_n(a+b) = \sum_{i \in \mathbf{Z}} h_i(a) h_{n-i}(b)$.

If A has a basis $a_1, \dots, a_m$ then $h(A)$ is the polynomial algebra generated by elements $h_n(a_i)$ for $n > 0$, $1 \leq i \leq m$. An action of G on A induces an action of G on $h(A)$ in the obvious way.

Lemma 5.1. *The cohomology ring $\hat{H}^*(g, h(\mathbf{Z}_p[G]))$ is the polynomial algebra over $\mathbf{F}_p$ generated by the ordinary elements $h_n(g_0) + h_n(g_1) + \cdots + h_n(g_{p-1})$ for $n > 0$.*

Proof. This follows from the fact that $h(\mathbf{Z}_p[G])$ is the tensor product of the rings A_n, where A_n is the polynomial algebra generated by the elements $h_n(g_i)$ for $0 \leq i < p$. We see that A_n is isomorphic to the symmetric algebra $S^*(\mathbf{Z}_p[G])$ whose cohomology is given by lemma 2.8, and we then apply corollary 2.2 to finish the proof. (Notice that the space spanned by the elements $h_n(g_i)$ for $0 \leq i < p$ is not $h_n(\mathbf{Z}_p[G])$; in fact, the latter is not even a $\mathbf{Z}_p$-module.) This proves lemma 5.1.

Proposition 5.2. *The cohomology ring $\hat{H}^*(g, h(I))$ is isomorphic to the free exterior algebra with one super generator in each positive degree not divisible by p. The automorphism -1 of I multiplies each generator by -1 and hence acts as -1 on $\hat{H}^1(g, h(I))$ and as 1 on $\hat{H}^0(g, h(I))$.*

Proof. The algebra $h(I)$ is the quotient of $h(\mathbf{Z}_p[G])$ by the ideal generated by the elements $h_n(N_G)$. We let R_m be the quotient of $h(\mathbf{Z}_p[G])$ by the elements $h_n(N_G)$ for $n \leq m$, and we will prove by induction on m that $\hat{H}^*(R_m)$ is the tensor product of the free polynomial algebra generated by the ordinary elements $h_n(g_0) + h_n(g_1) + \cdots + h_n(g_{p-1})$ (of degree n) for $n > m/p$ and the free exterior algebra generated by super elements of each degree n with $0 < n \leq m$, $(p, n) = 1$ (of degree n).

To do this we look at the exact sequence

$$0 \to R_{m-1} \to R_{m-1} \to R_m \to 0$$

where the map from R_{m-1} to R_{m-1} is given by multiplication by $h_m(N_G)$, and work out the cohomology of R_m using the cohomology exact sequence of this short exact sequence. We have to consider the cases $p|m$ and $(p, m) = 1$ separately.

If $(p, m) = 1$ then multiplication by $h_m(N_G)$ induces the zero map on cohomology, so that $\hat{H}^*(g, R_m)$ is the sum of $\hat{H}^*(g, R_{m-1})$ and $\hat{H}^*(g, R_{m-1})$ with the degree shifted by m and with the ordinary and super parts exchanged. In other words, $\hat{H}^*(g, R_m)$ is the tensor product of $\hat{H}^*(g, R_{m-1})$ with an exterior algebra generated by one super element of degree m. This proves the induction step when $(p, m) = 1$.

If $p|m$ then multiplication by $h_m(N_G)$ induces an injective map on cohomology, so that $\hat{H}^*(g, R_m)$ is the quotient of $\hat{H}^*(g, R_{m-1})$ by the image of $h_m(N_G)$, in other words it is just $\hat{H}^*(g, R_{m-1})$ with a polynomial generator of degree m killed off.

Hence we see that to go from $\hat{H}^*(h(R_{m-1}))$ to $\hat{H}^*(h(R_m))$ we either kill off a polynomial generator or add an exterior algebra generator. This proves the statement about $\hat{H}^*(h(R_m))$ for all m by induction, and hence proves proposition 5.2.

For completeness we remark that the cohomology ring $\hat{H}^*(g, h(\mathbf{Z}_p))$ is a polynomial algebra over $\mathbf{F}_p$ with one ordinary generator of each positive degree.

For any $\mathbf{Z}_p$-module A we define ω to be the automorphism of $h(A)$ taking $h_n(a)$ to $(-1)^n h_n(-a)$. We define $h_\omega(A)$ to be the largest quotient ring of $h(A)$ on which the automorphism ω acts trivially. (Notice that this is smaller than the largest quotient module on which ω acts trivially.)

Lemma 5.3. *The cohomology ring $\hat{H}^*(g, h_\omega(\mathbf{Z}_p[G]))$ is the polynomial ring on ordinary generators of degrees $(2n+1)p$ for $n \geq 0$.*

Proof. The algebra $h_\omega(\mathbf{Z}_p[G])$ is the polynomial algebra generated by the elements $h_{2n+1}(g_i)$ for $0 \leq i < p$, $n \geq 0$, and lemma 5.3 follows from this.

Lemma 5.4. *The cohomology ring $\hat{H}^*(g, h_\omega(I))$ is the exterior algebra on generators of degrees $(2n+1)$ for $n \geq 0$, $(n,p) = 1$. In particular it is generated (as a ring) by super elements of odd degrees, so that $\hat{H}^0(g, h_\omega(I))$ vanishes in odd degrees and $\hat{H}^1(g, h_\omega(I))$ vanishes in even degrees.*

This follows from lemma 5.3 in the same way that lemma 5.2 follows from 5.1.

Remark. The ring $h(\mathbf{Z}_p)$ can be identified with the ring of symmetric functions over $\mathbf{Z}_p$ if we identify $h_n(1)$ with the n'th complete symmetric function. In this case the automorphism ω taking $h_n(1)$ to $(-1)^n h_n(-1)$ is just the automorphism ω of [Mac, p. 14] taking the complete symmetric functions to the elementary symmetric functions.

Remark. More generally we can form a quotient ring associated to any automorphism ω of A of order n prime to p such that $h_\omega(A)$ is the quotient ring associated to the automorphism $\omega = -1$ of A. To do this we let R_p be the unramified extension of $\mathbf{Z}_p$ generated by a primitive n'th root of unity ζ. We then form the largest quotient ring of $h(A) \otimes R_p$ whose elements are fixed by the automorphism taking $h_n(a)$ to $\zeta^n h_n(\omega(a))$. For example this space appears when we try to construct the monster vertex algebra from a fixed point free automorphism ω of the Leech lattice Λ.

The extraspecial group 2^{1+24} occurring in the centralizer of an element of type $2B$ in M has a unique 2^{12}-dimensional irreducible module A over $\mathbf{Z}[1/2]$. Any element of odd order in $\mathrm{Aut}(\Lambda)$ has an induced action on 2^{1+24} and on A.

Lemma 5.5. *If g is an element of order 3, 5, 7, or 13 acting on the Leech lattice Λ with no nonzero fixed vectors then as a $\mathbf{Z}_p[G]$-module, $A \otimes \mathbf{Z}_p$ is the sum of $\mathbf{Z}_p$ and some copies of $\mathbf{Z}_p[G]$.*

Proof. We let B be the 2^{24}-dimensional 2^{1+24}-module $A \otimes A$. This is isomorphic to the group ring of 2^{24}. The element g acts fixed point freely on the group $2^{24} = \Lambda/2\Lambda$ because it acts fixed point freely on Λ and has odd order, so as a module over G, $B \otimes \mathbf{Z}_p$ is the sum of $\mathbf{Z}_p$ and some copies of $\mathbf{Z}_p[G]$, and the Tate cohomology groups are therefore $\hat{H}^0(g, B \otimes \mathbf{Z}_p) = \mathbf{Z}/p\mathbf{Z}$, $\hat{H}^1(g, B \otimes \mathbf{Z}_p) = 0$. As $\hat{H}^*(g, B \otimes \mathbf{Z}_p) = \hat{H}^*(g, A \otimes \mathbf{Z}_p) \otimes \hat{H}^*(g, A \otimes \mathbf{Z}_p)$ we see that $\hat{H}^*(g, A \otimes \mathbf{Z}_p)$ is either an ordinary or a super vector space over $\mathbf{F}_p$ of dimension 1.

Therefore as a G module, $A \otimes \mathbf{Z}_p$ is the sum of some copies of $\mathbf{Z}_p[G]$ and either $\mathbf{Z}_p$ or I. But $\dim(A) = 2^{12} \equiv 1 \bmod p$ as $(p-1)|12$ which rules out the second possibility. Therefore $\hat{H}^0(g, A \otimes \mathbf{Z}_p) = \mathbf{Z}/p\mathbf{Z}$, $\hat{H}^1(g, A \otimes \mathbf{Z}_p) = 0$. This proves lemma 5.5.

A similar argument can be used to calculate $\hat{H}^*(g, A)$ for any element g of odd prime order p in $\mathrm{Aut}(\Lambda)$. If $2n$ is the dimension of the subspace of Λ fixed by g then n is an integer with $2^n \equiv \pm 1 \bmod p$. Exactly one of the two cohomology groups $\hat{H}^*(g, A)$ vanishes and the other has dimension 2^n over $\mathbf{F}_p$. The group $\hat{H}^1(g, A)$ vanishes if $2^n \equiv 1 \bmod p$, and the group $\hat{H}^0(g, A)$ vanishes if $2^n \equiv -1 \bmod p$. There are some cases where it is $\hat{H}^0(g, A)$ and not $\hat{H}^1(g, A)$ that vanishes; for example, if g is the element of order 5 with trace -1 on Λ then $\hat{H}^0(g, A) = 0$ and $\hat{H}^1(g, A) = (\mathbf{Z}/5\mathbf{Z})^4$.

6. Elements of type $3B$, $5B$, $7B$, and $13B$.

We use the result of the previous section to calculate the cohomology groups $\hat{H}^i(g, V[1/2])$ when $g \in M$ has type $3B$, $5B$, $7B$, or $13B$.

Theorem 6.1. *If $g \in M$ has type $3B$, $5B$, $7B$, or $13B$ and σ is the element of order 2 generating the center of $C_M(g)/O_p(C_M(g))$ then $O_p(C_M(g))$ acts trivially on ${}^gV$ and σ fixes the ordinary part of ${}^gV$ and acts as -1 on the super part.*

Proof. We prove this by calculating the action of σ on $\hat{H}^*(g, V[1/2])$ explicitly. We recall from [B-R] that the $\mathbf{Z}[1/2]$-form $V[1/2]$ of Frenkel, Lepowsky and Meurman's monster vertex algebra [FLM] is the sum of two pieces V^0 and V^1 which are the $+1$ and -1 eigenspaces of an element σ of type $2B$. (Unfortunately the details for the construction of this $\mathbf{Z}[1/2]$-form have not been published anywhere.) We now show that $\hat{H}^0(g, V^1) = \hat{H}^1(g, V^0) = 0$.

The space V^0 is the subspace of $V_\Lambda[1/2]$ fixed by the automorphism induced by -1 acting on the Leech lattice Λ, where $V_\Lambda[1/2] = V_\Lambda \otimes \mathbf{Z}[1/2]$, and V_Λ is the integral form of the vertex algebra of the Leech lattice, described in [B-R]. As in [B-R], the space V_Λ is the tensor product of a twisted group ring $\mathbf{Z}[\hat{\Lambda}]$ and a space isomorphic to $h(\Lambda)$. The cohomology $\hat{H}^*(g, \mathbf{Z}[\hat{\Lambda}])$ is just $\mathbf{Z}/p\mathbf{Z}$ as in [B-R] because g acts fixed point freely on Λ. By proposition 5.2, the element -1 of $\mathrm{Aut}(\hat\Lambda)$ acts as $+1$ on $\hat H^0(g,h(\Lambda))$ and as -1 on $\hat H^1(g,h(\Lambda))$. Therefore $\hat H^1(g,V^0)$ vanishes because it is isomorphic to the subspace of $\hat H^1(g,h(\Lambda))$ fixed by $-1\in\mathrm{Aut}(\Lambda)$.

The space V^1 is the subspace of elements of integral weight of the tensor product $A\otimes h_\omega(\Lambda\otimes\mathbf{Z}_p)$, where A is the 2^{12} dimensional module for 2^{1+24} and $h_\omega(\Lambda\otimes\mathbf{Z}_p)$ has its grading halved and then shifted by $3/2$. By lemma 5.5, $\hat H^*(g,A)=\mathbf{F}_p$, so $\hat H^*(g,A\otimes h_\omega(\Lambda\otimes\mathbf{Z}_p))=\hat H^*(g,h_\omega(\Lambda\otimes\mathbf{Z}_p))$. By lemma 5.4 the cohomology ring $\hat H^*(g,h_\omega(\Lambda\otimes\mathbf{Z}_p))$ is generated by super elements of odd degree, so $\hat H^1(g,h_\omega(\Lambda\otimes\mathbf{Z}_p))$ vanishes in even degrees and $\hat H^1(g,h_\omega(\Lambda\otimes\mathbf{Z}_p))$ vanishes in odd degrees. Therefore $\hat H^0(g,A\otimes h_\omega(\Lambda\otimes\mathbf{Z}_p))$ vanishes in integral degrees, so $\hat H^0(g,V^1)=0$.

This shows that the element σ acts as 1 on $\hat H^0(g,V[1/2])=\hat H^0(g,V_\Lambda)=\hat H^0(g,h(\Lambda\otimes\mathbf{Z}_p))$ and as -1 on $\hat H^1(g,V[1/2])=\hat H^1(g,A\otimes h_\omega(\Lambda\otimes\mathbf{Z}_p))$.

Finally we show that $O_p(C_M(g))$ acts trivially on ${}^gV$. The element σ acts trivially on the center $\langle g\rangle$ of the extraspecial group $p^{1+24/(p-1)}$ and acts as -1 on the quotient $p^{24/(p-1)}$. The element g acts trivially on ${}^gV$ so we get an action of $p^{24/(p-1)}$ on ${}^gV$. As σ acts as 1 on the even part of ${}^gV$ and as -1 on the odd part, it commutes with all automorphisms of ${}^gV$, so the group $p^{24/(p-1)}$ must act trivially on ${}^gV$. This proves theorem 6.1.

The group $C_M(g)$ has structure $3^{1+12}.2.Suz$, $5^{1+6}.2.HJ$, $7^{1+4}.2.A_7$, or $13^{1+2}.2.A_4$, so we get modular vertex superalgebras acted on faithfully by the groups $2.Suz$, $2.HJ$, $2.A_7$, and $2.A_4$ whose modular characters are given by Hauptmoduls. We can calculate the characters of both the ordinary and super parts of these superalgebras by using the fact that the characters of their sum and difference are both given in terms of known Hauptmoduls.

It seems likely that if g has type $2B$ then the vertex superalgebra acted on by $2^{24}.Co_1$ constructed in [B-R] is acted on trivially by the 2^{24} subgroup, but this has not yet been proved. The proof given above for the corresponding fact for elements of odd prime order fails for order 2 because an automorphism mapping each element of 2^{24} to its inverse is still the identity automorphism.

As an example, we work out the dimensions of the ordinary and super parts of ${}^gV$ in the case when g has type $3B$. The function $\sum_n \mathrm{Tr}(1|{}^gV)$ is equal to the Hauptmodul of the element g of type $3B$ in the monster, which is

$$q^{-1}+54q-76q^2-243q^3+1188q^4-1384q^5-\cdots,$$

and the function $\sum_n \mathrm{Tr}(\sigma|{}^gV)$ is equal to the Hauptmodul of the element σg of type $6B$ in the monster, which is

$$q^{-1}+78q+364q^2+1365q^3+4380q^4+12520q^5+\cdots$$

so we find that the dimension of the ordinary part of ${}^gV_n$ is the coefficient of q^n of

$$q^{-1}+66q+144q^2+561q^3+2784q^4+5568q^5+\cdots$$

and the dimension of the super part of ${}^gV_n$ is the coefficient of q^n of

$$12q+220q^2+804q^3+1596q^4+6952q^5\cdots.$$

These series can be written as sums of dimensions of ordinary representations of the groups $3.Suz$ and $6.Suz$ as

$$q^{-1}+66q+(1+143)q^2+(429+66+66)q^3+(66+66+78+429+2145)q^4+(4\times1+4\times143+2\times780+3432)q^5+\cdots$$

and

$$12q+220q^2+(780+12+12)q^3+(780+780+12+12+12)q^4+(4\times220+2\times572+4928)q^5+\cdots.$$

(Some of the decompositions are ambiguous; for example $1+143$ could be $66+78$. We have chosen $1+143$ instead of $66+78$ for a reason that will appear in a moment.) At first sight this seems to rule out a vertex algebra structure on any lift to characteristic 0, as the homogeneous components V_n, $V_{n+1},\ldots$ have to increase. However we can get around this by rescaling the grading by a factor of $1/3$. The data above seem consistent with the existence of a $\frac{1}{3}\mathbf{Z}$-graded vertex superalgebra $W=\sum_{3n\in\mathbf{Z}}W_n$ such that the mod

3 reduction of W_n is V_{3n}. The vertex superalgebra W is probably acted on by $6.Suz$, with the element of order 3 in the center acting as ω^{3n} on W_n.

There is a second modular vertex super algebra acted on by each of the groups $2.Suz$, $2.HJ$, $2.A_7$, and $2.A_4$, which can be constructed as $\hat{H}^*(g, V_\Lambda)$ where g is a fixed point free automorphism of order 3, 5, 7, or 13 of the Leech lattice Λ. The ordinary part of this superalgebra is the same as the ordinary part of the superalgebra constructed from the monster vertex algebra, but its super part is different; for example, its degree 0 piece does not vanish.

7. Open problems and conjectures.

For more open problems in this area see section 7 of [B-R].

At the end of section 6 we saw that the vertex superalgebra of an element of type $3B$ looks as if it might be the reduction mod 3 of a superalgebra in characteristic 0. More generally something similar seems to happen for some other elements of the monster, as described in the following conjecture.

Conjecture. *For each element $g \in M$ of order n there is a $\frac{1}{n}\mathbf{Z}$-graded super module ${}^g\hat{V} = \sum_{i\in\frac{1}{n}\mathbf{Z}} V_i$ over the ring $\mathbf{Z}[e^{2\pi i/n}]$ with the following properties.*

1. *${}^g\hat{V}$ is often a vertex superalgebra with a conformal vector and a self dual invariant symmetric bilinear form. (For example, it seems to be a vertex algebra when g is of type $1A$, $2B$, $3B$, $5B$, $7B$, $13B$, or $3C$, but possibly not if g has type $2A$ or $3A$.)*
2. *${}^1\hat{V}$ is a self dual integral form of the monster vertex algebra (probably the one conjecturally described in lemma 7.1 of [B-R]).*
3. *If g has prime order then the reduction mod p of ${}^g\hat{V}$ is the modular vertex superalgebra ${}^gV$ associated to g (at least when its grading is multiplied by n.)*
4. *If all coefficients of the Hauptmodul of g are nonnegative then the super part of ${}^g\hat{V}$ vanishes. In this case ${}^g\hat{V}$ should be the same as the "twisted sector" of g that appears in Norton's generalized moonshine conjectures [N]. (But notice that if the Hauptmodul of g has negative coefficients then ${}^g\hat{V}$ is certainly not the twisted sector of g; for example, ${}^g\hat{V}$ is a super vector space and has a nontrivial piece of degree 0.)*
5. *${}^g\hat{V}$ is acted on by a central extension $(\mathbf{Z}/n\mathbf{Z}).C_M(g)$ of $C_M(g)$ by $\mathbf{Z}/n\mathbf{Z}$. This central extension contains an element of order 1 or 2 acting as -1 on the super part of ${}^g\hat{V}$ and as 1 on the ordinary part.*
6. *If g and h are commuting elements of M of coprime orders and $\hat{g}$ is the lift of g to the central extension of $C_M(h)$ with the same order as g, then*
$$\mathrm{Tr}(\hat{g}|{}^h\hat{V}) = \mathrm{Tr}(gh|{}^1\hat{V}).$$
(This identity is often false if the orders of g and h are not coprime.)
7. *If g and h commute then $\hat{H}^*(\hat{g}, {}^h\hat{V})$ is (essentially) the reduction mod $|g|$ of ${}^{gh}V$. (Actually this is not quite correct as stated, because the reduction mod $|g|$ will be defined over some nilpotent extension of $\mathbf{Z}/|g|\mathbf{Z}$, and we should then take the tensor product over this ring with $\mathbf{Z}/|g|\mathbf{Z}$.)*

These conjectures are similar to Norton's generalized moonshine conjectures [N] because both associate some graded space with each element g of the monster. However they treat the problem of negative coefficients in the Hauptmodul $T_g(\tau)$ in a different way: Norton's conjectures use the fact that $T_g(-1/\tau)$ has nonnegative coefficients, which are supposed to be the dimensions of some vector spaces, while the conjectures above allow super vector spaces which may have negative super dimension. Perhaps both Norton's conjectures and the conjectures above are special cases of some conjecture which associates a $\mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}$-graded super space acted on by a central extension $\mathbf{Z}/n\mathbf{Z}.C_M(g)$ to each element $g \in M$ of order n.

We finish by listing a few other questions.

1. Is the group $C_M(g)/O_p(C_M(g))$ the full automorphism group of the modular vertex algebra ${}^gV$? If g has type $3C$ it seems possible that it is not, and the full automorphism group may be $E_8(\mathbf{F}_3)$. Notice that if g has type $2B$ then it is not yet known that $O_2(C_M(g))$ acts trivially on ${}^gV$.
2. Replace the revolting argument of section 4 that involves computer calculations with a more conceptual proof. More generally, suppose we have coefficients $c(n)$ of some function such that the coefficient of $r^m q^n$ in
$$r^{-1}\prod_{m>0, n\in\mathbf{Z}}(1-r^m q^n)^{c(mn)}$$

vanishes whenever $(mn, N) = 1$ for some fixed integer N. What does this imply about the coefficients $c(n)$? (There are many solutions to this given by taking the $c(n)$'s to be the coefficients of some Hauptmodul of level N.)

3. What happens when we apply the argument of section 3 to some automorphism of prime order of the fake monster Lie algebra? Do the infinite products we get represent interesting functions?
4. In [B section 10] it was suggested that there should be Lie superalgebras associated with elements g of the monster, but it was not clear what the dimensions of homogeneous components of these superalgebras should be in the cases when the coefficients of the Hauptmodul of g were neither all positive nor alternating in sign. The results of section 6 suggest what to do in this case: the sum of the dimensions of the ordinary and super parts should also be given by the coefficients of another Hauptmodul.

Monstrous moonshine

En mathématiques, **monstrous moonshine** est un terme anglais conçu par John Horton Conway et Simon P. Norton en 1979, utilisé pour décrire la connexion, alors totalement inattendue, entre le groupe Monstre *M* et les formes modulaires (en particulier la fonction *j*).

Précisément, Conway et Norton, suivant une observation initiale de John McKay, trouvèrent que le développement de Fourier de $j(\tau)$ (suite A000521 de l'OEIS, où τ désigne le quotient des demi-périodes `(en)`) pouvait être exprimé en termes de combinaisons linéaires des dimensions des représentations irréductibles de *M* (suite A001379 de l'OEIS)

$$j(\tau) = \frac{1}{q} + 744 + 196884\,q + 21493760\,q^2 + 864299970\,q^3 + \cdots$$

où $q = e^{2\pi i\tau}$ et

$$\begin{aligned} 1 &= 1 \\ 196884 &= 196883 + 1 \\ 21493760 &= 21296876 + 196883 + 1 \\ 864299970 &= 842609326 + 21296876 + 2 \cdot 196883 + 2 \cdot 1 \\ &\vdots \end{aligned}$$

Conway et Norton formulèrent des conjectures concernant les fonctions $j_g(q)$ obtenues en remplaçant les traces sur l'élément neutre par les traces sur d'autres éléments *g* de *M*. La partie la plus saisissante de ces conjectures est que toutes ces fonctions sont de genre zéro. En d'autres termes, si G_g est le sous-groupe de $SL_2(\mathbb{R})$ qui fixe $j_g(q)$, alors le quotient du demi-plan supérieur du plan complexe par G_g est une sphère privée d'un nombre fini de points, correspondant aux formes paraboliques de G_g.

Il s'avère que derrière *monstrous moonshine* se trouve une certaine théorie des cordes ayant le groupe Monstre comme groupe de symétries ; les conjectures faites par Conway et Norton furent démontrées par Richard Ewen Borcherds en 1992 en utilisant le théorème de Goddard-Thorn `(en)` issu de la théorie des cordes, ainsi que la théorie des algèbres vertex et des algèbres de Kac-Moody généralisées `(en)`. Borcherds reçut la médaille Fields pour son travail, et des connexions supplémentaires entre *M* et la fonction *j* furent découvertes ultérieurement.

Versions formelles des conjectures de Conway et Norton

La première conjecture faite par Conway et Norton fut ce que l'on appela la « conjecture *moonshine* » ; elle établit qu'il existe un *M*-module gradué de dimension infinie

$$V = \bigoplus_{m \geq -1} V_m$$

avec $\dim(V_m) = c(m)$ pour tout *m*, où

$$j(q) = \sum_{m \geq -1} c_m q^m .$$

De ceci, il s'ensuit que chaque élément *g* de *M* agit sur chaque V_m et possède une valeur de caractère

$$\chi_m(g) = \operatorname{tr}(g|_{V_m})$$

qui peut être utilisée pour construire la **série de McKay-Thompson** de *g* :

$$T_g(q) = \sum_{m \geq -1} \chi_m(g) q^m .$$

La deuxième conjecture de Conway et Norton établit ensuite qu'avec *V* comme ci-dessus, pour chaque élément *g* de *M*, il existe un sous-groupe *K* de $PSL_2(\mathbb{R})$, de genre zéro, commensurable avec le groupe modulaire Γ = $PSL_2(\mathbf{Z})$, et tel que $T_g(q)$ soit la fonction modulaire principale normalisée pour *K*.

Le module Monstre

Il fut montré plus tard par A. O. L. Atkin, Paul Fong et Frederic L. Smith en utilisant des calculs informatiques qu'il existe en effet une représentation graduée de dimension infinie du groupe Monstre dont les séries de McKay-Thompson sont précisément les Hauptmoduls trouvés par Conway et Norton, Igor Frenkel **(en)**, James Lepowsky **(en)** et Arne Meurman **(en)** construisirent explicitement cette représentation en utilisant les opérateurs vertex. Le module résultant est appelé le module Monstre, ou algèbre vertex Monstre **(en)**.

La démonstration de Borcherds

La démonstration de Richard Ewen Borcherds de la conjecture de Conway et Norton peut être séparée en cinq étapes majeures comme ce qui suit :

1. On construit une algèbre vertex *V* qui est une algèbre graduée fournissant les représentations moonshine sur *M*, et on vérifie que le module Monstre possède une structure d'algèbre vertex invariante sous l'action de *M*.
2. On construit une algèbre de Lie $\mathcal{M}$ à partir de *V* en utilisant le théorème de Goddard-Thorn ; ceci est une algèbre de Lie Kac-Moody généralisée.
3. On calcule pour $\mathcal{M}$ une équations des dénominateurs **(en)**, reliée aux coefficients de $j(q)$.
4. On calcule des équations tordues des dénominateurs, qui sont reliées de manière similaire aux séries $T_g(q)$.
5. Toutes ces équations sont utilisées pour déterminer les nombres c en utilisant les opérateurs

5. Toutes ces équations sont utilisées pour déterminer les nombres c_m, en utilisant les opérateurs de Hecke **(en)**, l'homologie d'algèbre de Lie **(en)** et les opérations d'Adams **(en)**.

Ainsi, la démonstration est achevée. Borcherds fut plus tard cité comme ayant dit « j'étais sur la Lune lorsque j'ai démontré la conjecture *moonshine* (clair de lune) » et « Je me demande quelquefois si c'est ce que l'on ressent lorsque l'on prend certaines drogues. Je ne le sais pas actuellement, comme je n'ai pas testé cette théorie personnelle. »

Pourquoi « monstrous moonshine » ?

Le terme « *monstrous moonshine* » fut inventé par Conway, qui, lorsque John McKay lui dit à la fin des années 1970 que les coefficients de q (concrètement 196 884) étaient précisément la dimension de l'algèbre de Griess **(en)** (et ainsi exactement un de plus que le degré de la plus petite représentation fidèle complexe du groupe Monstre), répondit que ceci était « *moonshine* » (au sens de « dingue » ou « idées folles »). Ainsi, le terme fait référence non seulement au groupe Monstre M, mais aussi à la folie perçue concernant la relation compliquée entre M et la théorie des fonctions modulaires.

Cependant, « *moonshine* » est aussi un mot d'argot pour un whisky distillé illégalement, et en fait, le nom peut être expliqué à la lumière de ceci. Le groupe Monstre fut étudié dans les années 1970 par les mathématiciens Jean-Pierre Serre, Andrew Ogg **(en)** et John Griggs Thompson ; ils étudièrent le quotient du plan hyperbolique **(en)** par les sous-groupes de $SL(2,\mathbf{R})$, en particulier le normalisateur $\Gamma_0(p)^+$ du sous-groupe de congruences **(en)** $\Gamma_0(p)$ dans $SL(2,\mathbf{R})$. Ils trouvèrent que la surface de Riemann obtenue en prenant le quotient du plan hyperbolique par $\Gamma_0(p)^+$ est de genre zéro si et seulement si p est 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 47, 59 ou 71 (c'est-à-dire, un nombre premier super-singulier), et lorsque Ogg entendit plus tard parler du groupe Monstre et remarqua que ces nombres étaient précisément les facteurs premiers de la taille de M, il prépara un article offrant une bouteille de whisky Jack Daniel's à quiconque pouvait expliquer ce fait[1].

Proof of the Umbral Moonshine Conjecture

John F. R. Duncan, Michael J. Griffin and Ken Ono

2015 November 25

Abstract

The Umbral Moonshine Conjectures assert that there are infinite-dimensional graded modules, for prescribed finite groups, whose McKay-Thompson series are certain distinguished mock modular forms. Gannon has proved this for the special case involving the largest sporadic simple Mathieu group. Here we establish the existence of the umbral moonshine modules in the remaining 22 cases.

1 Introduction and Statement of Results

Monstrous moonshine relates distinguished modular functions to the representation theory of the Monster, $\mathbb{M}$, the largest sporadic simple group. This theory was inspired by the famous observations of McKay and Thompson in the late 1970s [18,51] that

$$\begin{aligned} 196884 &= 1 + 196883, \\ 21493760 &= 1 + 196883 + 21296876. \end{aligned}$$

The left hand sides here are familiar as coefficients of Klein's modular function (note $q := e^{2\pi i\tau}$),

$$J(\tau) = \sum_{n=-1}^{\infty} c(n)q^n := j(\tau) - 744 = q^{-1} + 196884q + 21493760q^2 + \dots.$$

The sums on the right hand sides involve the first three numbers arising as dimensions of irreducible representations of $\mathbb{M}$,

$$1,\ 196883,\ 21296876,\ 842609326,\ \dots,\ 258823477531055064045234375.$$

Thompson conjectured that there is a graded infinite-dimensional $\mathbb{M}$-module

$$V^\natural = \bigoplus_{n=-1}^{\infty} V_n^\natural,$$

satisfying $\dim(V_n^\natural) = c(n)$. For $g \in \mathbb{M}$, he also suggested [50] to consider the graded-trace functions

$$T_g(\tau) := \sum_{n=-1}^{\infty} \mathrm{tr}(g|V_n^\natural)q^n,$$

now known as the *McKay-Thompson series*, that arise from the conjectured $\mathbb{M}$-module $V^\natural$. Using the character table for $\mathbb{M}$, it was observed [18,50] that the first few coefficients of each $T_g(\tau)$ coincide with those of a generator for the function field of a discrete group $\Gamma_g < SL_2(\mathbb{R})$, leading Conway and Norton [18] to their famous *Monstrous Moonshine Conjecture*: This is the claim that for each $g \in \mathbb{M}$ there is a specific *genus zero* group Γ_g such that $T_g(\tau)$ is the unique normalized *hauptmodul* for Γ_g, i.e., the unique Γ_g-invariant holomorphic function on $\mathbb{H}$ which satisfies $T_g(\tau) = q^{-1} + O(q)$ as $\Im(\tau) \to \infty$, and remains bounded near any cusp not equivalent to the infinite one.

In a series of ground-breaking works, Borcherds introduced vertex algebras [2], and generalized Kac–Moody Lie algebras [3, 4], and used these notions to prove [5] the Monstrous Moonshine Conjecture of Conway and Norton. He confirmed the conjecture for the module $V^\natural$ constructed by Frenkel, Lepowsky, and Meurman [30–32] in the early 1980s. These results provide much more than the predictions of monstrous moonshine. The $\mathbb{M}$-module $V^\natural$ is a vertex operator algebra, one whose automorphism group is precisely $\mathbb{M}$. The construction of Frenkel, Lepowsky and Meurman can be regarded as one of the first examples of an *orbifold conformal field theory*. (Cf. [23].) Here the orbifold in question is the quotient $\left(\mathbb{R}^{24}/\Lambda_{24}\right)/(\mathbb{Z}/2\mathbb{Z})$, of the 24-dimensional torus $\Lambda_{24} \otimes_{\mathbb{Z}} \mathbb{R}/\Lambda_{24} \simeq \mathbb{R}^{24}/\Lambda_{24}$ by the Kummer involution $x \mapsto -x$, where Λ_{24} denotes the Leech lattice.

We refer to [24,32,35,36] for more on monstrous moonshine.

In 2010, Eguchi, Ooguri, and Tachikawa reignited moonshine with their observation [28] that dimensions of some representations of M_{24}, the largest sporadic simple Mathieu group (cf. e.g. [20, 21]), are multiplicities of superconformal algebra characters in the K3 elliptic genus. This observation suggested a manifestation of moonshine for M_{24}: Namely, there should be an infinite-dimensional graded M_{24}-module whose McKay-Thompson series are holomorphic parts of *harmonic Maass forms*, the so-called *mock modular forms*. (See [45, 54, 55] for introductory accounts of the theory of mock modular forms.)

Following the work of Cheng [10], Eguchi and Hikami [27], and Gaberdiel, Hohenegger, and Volpato [33, 34], Gannon established the existence of this infinite-dimensional graded M_{24}-module in [37].

It is natural to seek a general mathematical and physical setting for these results. Here we consider the mathematical setting, which develops from the close relationship between the monster group $\mathbb{M}$ and the Leech lattice Λ_{24}. Recall (cf. e.g. [20]) that the Leech lattice is even, unimodular, and positive-definite of rank 24. It turns out that M_{24} is closely related to another such lattice. Such observations led Cheng, Duncan and Harvey to further instances of moonshine within the setting of even unimodular positive-definite lattices of rank 24. In this way they arrived at the *Umbral Moonshine Conjectures* (cf. §5 of [15], §6 of [16], and §2 of [17]), predicting the existence of 22 further, graded infinite-dimensional modules, relating certain finite groups to distinguished mock modular forms.

To explain this prediction in more detail we recall Niemeier's result [43] that there are 24 (up to isomorphism) even unimodular positive-definite lattices of rank 24. The Leech lattice is the unique one with no root vectors (i.e. lattice vectors with norm-square 2), while the other 23 have root systems with full rank, 24. These *Niemeier root systems* are unions of simple simply-laced root systems with the same Coxeter numbers, and are given explicitly as

$$\begin{gathered} A_1^{24},\ A_2^{12},\ A_3^{8},\ A_4^{6},\ A_6^{4},\ A_{12}^{2}, \\ A_5^4D_4,\ A_7^2D_5^2,\ A_8^3,\ A_9^2D_6,\ A_{11}D_7E_6,\ A_{15}D_9,\ A_{17}E_7,\ A_{24}, \\ D_4^6,\ D_6^4,\ D_8^3,\ D_{10}E_7^2,\ D_{12}^2,\ D_{16}E_8,\ D_{24}, E_6^4,\ E_8^3, \end{gathered} \tag{1.1}$$

in terms of the standard ADE notation. (Cf. e.g. [20] or [39] for more on root systems.)

For each Niemeier root system X let N^X denote the corresponding unimodular lattice, let W^X denote the (normal) subgroup of $\mathrm{Aut}(N^X)$ generated by reflections in roots, and define the *umbral group* of X by setting

$$G^X := \mathrm{Aut}(N^X)/W^X. \tag{1.2}$$

(See §A.1 for explicit descriptions of the groups G^X.)

Let m^X denote the Coxeter number of any simple component of X. An association of distinguished $2m^X$-vector-valued mock modular forms $H_g^X(\tau) = (H_{g,r}^X(\tau))$ to elements $g \in G^X$ is described and analyzed in [15–17].

For $X = A_1^{24}$ we have $G^X \simeq M_{24}$ and $m^X = 2$, and the functions $H_{g,1}^X(\tau)$ are precisely the mock modular forms assigned to elements $g \in M_{24}$ in the works [10, 27, 33, 34] mentioned above. Generalizing the M_{24} moonshine initiated by Eguchi, Ooguri and Tachikawa, we have the following conjecture of Cheng, Duncan and Harvey (cf. §2 of [17] or §9.3 of [24]).

Conjecture (Umbral Moonshine Modules)**.** Let X be a Niemeier root system X and set $m := m^X$. There is a naturally defined bi-graded infinite-dimensional G^X-module

$$\check{K}^X = \bigoplus_{r\in I^X} \bigoplus_{\substack{D\in\mathbb{Z},\ D\leq 0,\\ D=r^2 \pmod{4m}}} \check{K}^X_{r,-D/4m} \tag{1.3}$$

such that the vector-valued mock modular form $H^X_g = (H^X_{g,r})$ is a McKay-Thompson series for $\check{K}^X$ related[1] to the graded trace of g on $\check{K}^X$ by

$$H^X_{g,r}(\tau) = -2q^{-1/4m}\delta_{r,1} + \sum_{\substack{D\in\mathbb{Z},\ D\leq 0,\\ D=r^2 \pmod{4m}}} \operatorname{tr}(g|\check{K}^X_{r,-D/4m})q^{-D/4m} \tag{1.4}$$

for $r \in I^X$.

In (1.3) and (1.4) the set $I^X \subset \mathbb{Z}/2m\mathbb{Z}$ is defined in the following way. If X has an A-type component then $I^X := \{1, 2, 3, \ldots, m-1\}$. If X has no A-type component but does have a D-type component then $m = 2 \mod 4$, and $I^X := \{1, 3, 5, \ldots, m/2\}$. The remaining cases are $X = E_6^4$ and $X = E_8^3$. In the former of these, $I^X := \{1, 4, 5\}$, and in the latter case $I^X := \{1, 7\}$.

Remark. The functions $H^X_g(\tau)$ are defined explicitly in §B.3. An alternative description in terms of Rademacher sums is given in §B.4.

Here we prove the following theorem.

Theorem 1.1. *The umbral moonshine modules exist.*

Two remarks.

1) Theorem 1.1 for $X = A_1^{24}$ is the main result of Gannon's work [37].

2) The vector-valued mock modular forms $H^X = (H^X_{g,r})$ have "minimal" *principal parts*. This minimality is analogous to the fact that the original McKay-Thompson series $T_g(\tau)$ for the Monster are hauptmoduln, and plays an important role in our proof.

Example. Many of Ramanujan's mock theta functions [46] are components of the vector-valued umbral McKay-Thompson series $H^X_g = (H^X_{g,r})$. For example, consider the root system $X = A_2^{12}$, whose umbral group is a double cover $2.M_{12}$ of the sporadic simple Mathieu group M_{12}. In terms of Ramanujan's 3rd order mock theta functions

---

[1] In the statement of Conjecture 6.1 of [16] the function $H^X_{g,r}$ in (1.4) is replaced with $3H^X_{g,r}$ in the case that $X = A_8^3$. This is now known to be an error, arising from a misspecification of some of the functions H^X_g for $X = A_8^3$. Our treatment of the case $X = A_8^3$ in this work reflects the corrected specification of the corresponding H^X_g which is described and discussed in detail in [17].

$$\begin{aligned}
f(q) &= 1+\sum_{n=1}^{\infty}\frac{q^{n^2}}{(1+q)^2(1+q^2)^2\cdots(1+q^n)^2},\\
\phi(q) &= 1+\sum_{n=1}^{\infty}\frac{q^{n^2}}{(1+q^2)(1+q^4)\cdots(1+q^{2n})},\\
\chi(q) &= 1+\sum_{n=1}^{\infty}\frac{q^{n^2}}{(1-q+q^2)(1-q^2+q^4)\cdots(1-q^n+q^{2n})}\\
\omega(q) &= \sum_{n=0}^{\infty}\frac{q^{2n(n+1)}}{(1-q)^2(1-q^3)^2\cdots(1-q^{2n+1})^2},\\
\rho(q) &= \sum_{n=0}^{\infty}\frac{q^{2n(n+1)}}{(1+q+q^2)(1+q^3+q^6)\cdots(1+q^{2n+1}+q^{4n+2})},
\end{aligned}$$

we have that

$$\begin{aligned}
H^X_{2B,1}(\tau)=H^X_{2C,1}(\tau)=H^X_{4C,1}(\tau) &= -2q^{-\frac{1}{12}}\cdot f(q^2),\\
H^X_{6C,1}(\tau)=H^X_{6D,1}(\tau) &= -2q^{-\frac{1}{12}}\cdot \chi(q^2),\\
H^X_{8C,1}(\tau)=H^X_{8D,1}(\tau) &= -2q^{-\frac{1}{12}}\cdot \phi(-q^2),\\
H^X_{2B,2}(\tau)=-H^X_{2C,2}(\tau) &= -4q^{\frac{2}{3}}\cdot \omega(-q),\\
H^X_{6C,2}(\tau)=-H^X_{6D,2}(\tau) &= 2q^{\frac{2}{3}}\cdot \rho(-q).
\end{aligned}$$

See §5.4 of [16] for more coincidences between umbral McKay-Thompson series and mock theta functions identified by Ramanujan almost a hundred years ago.

Our proof of Theorem 1.1 involves the explicit determination of each G^X-module $\check{K}^X$ by computing the multiplicity of each irreducible component for each homogeneous subspace. It guarantees the existence and uniqueness of a $\check{K}^X$ which is compatible with the representation theory of G^X and the Fourier expansions of the vector-valued mock modular forms $H^X_g(\tau)=(H^X_{g,r}(\tau))$.

At first glance our methods do not appear to shed light on any deeper algebraic properties of the $\check{K}^X$, such as might correspond to the vertex operator algebra structure on $V^\natural$, or the monster Lie algebra introduced by Borcherds in [5]. However, we do determine, and utilize, specific recursion relations for the coefficients of the umbral McKay-Thompson series which are analogous to the replicability properties of monstrous moonshine formulated by Conway and Norton in §8 of [18] (cf. also [1]). More specifically, we use recent work [41] of Imamoḡlu, Raum and Richter, as generalized [42] by Mertens, to obtain such recursions. These results are based on the process of *holomorphic projection*.

Theorem 1.2. *For each $g\in G^X$ and $0<r<m$, the mock modular form $H^X_{g,r}(\tau)$ is replicable in the mock modular sense.*

A key step in Borcherds' proof [5] of the monstrous moonshine conjecture is the reformulation of replicability in Lie theoretic terms. We may speculate that the *mock modular replicability* utilized in this work will ultimately admit an analogous algebraic interpretation. Such a result remains an important goal for future work.

In the statement of Theorem 1.2, replicable means that there are explicit recursion relations for the coefficients of the vector-valued mock modular form in question. For example, we recall the recurrence formula for Ramanujan's third order mock theta function $f(q) = \sum_{n=0}^{\infty} c_f(n)q^n$ that was obtained recently by Imamoḡlu, Raum and Richter [41]. If $n \in \mathbb{Q}$, then let

$$\sigma_1(n) := \begin{cases} \sum_{d|n} d & \text{if } n \in \mathbb{Z}, \\ 0 & \text{otherwise,} \end{cases}$$

$$\mathrm{sgn}^+(n) := \begin{cases} \mathrm{sgn}(n) & \text{if } n \neq 0, \\ 1 & \text{if } n = 0, \end{cases}$$

and then define

$$d(N, \widetilde{N}, t, \widetilde{t}) := \mathrm{sgn}^+(N) \cdot \mathrm{sgn}^+(\widetilde{N}) \cdot \left(|N+t| - |\widetilde{N} + \widetilde{t}| \right).$$

Then for positive integers n, we have that

$$\sum_{\substack{m \in \mathbb{Z} \\ 3m^2+m \leq 2n}} \left(m + \frac{1}{6}\right) c_f\left(n - \frac{3}{2}m^2 - \frac{1}{2}m\right) = \frac{4}{3}\sigma(n) - \frac{16}{3}\sigma\left(\frac{n}{2}\right) - 2\sum_{\substack{a,b \in \mathbb{Z} \\ 2n=ab}} d\left(N, \widetilde{N}, \frac{1}{6}, \frac{1}{6}\right),$$

where $N := \frac{1}{6}(-3a+b-1)$ and $\widetilde{N} := \frac{1}{6}(3a+b-1)$, and the sum is over integers a, b for which $N, \widetilde{N} \in \mathbb{Z}$. This is easily seen to be a recurrence relation for the coefficients $c_f(n)$. The replicability formulas for all of the $H^X_{g,r}(\tau)$ are similar (although some of these relations are slightly more complicated and involve the coefficients of weight 2 cusp forms).

It is important to emphasize that, despite the progress which is represented by our main results, Theorems 1.1 and 1.2, the following important question remains open in general.

Question. *Is there a "natural" construction of $\check{K}^X$? Is $\check{K}^X$ equipped with a deeper algebra structure as in the case of the monster module $V^\natural$ of Frenkel, Lepowsky and Meurman?*

We remark that this question has been answered positively, recently, in one special case: A vertex operator algebra structure underlying the umbral moonshine module $\check{K}^X$ for $X = E_8^3$ has been described explicitly in [25]. See also [14, 26], where the problem of constructing algebraic structures that illuminate the umbral moonshine observations is addressed from a different point of view.

The proof of Theorem 1.1 is not difficult. It is essentially a collection of tedious calculations. We use the theory of mock modular forms and the character table for each G^X (cf. §A.2) to solve for the multiplicities of the irreducible G^X-module constituents of each homogeneous subspace in the alleged G^X-module $\check{K}^X$. To prove Theorem 1.1 it suffices to prove that these multiplicities are non-negative integers. To prove Theorem 1.2 we apply recent work [42] of Mertens on the holomorphic projection of weight $\frac{1}{2}$ mock modular forms, which generalizes earlier work [41] of Imamoḡlu, Raum and Richter.

In §2 we recall the facts about mock modular forms that we require, and we prove Theorem 1.2. We prove Theorem 1.1 in §3. The appendices furnish all the data that our method requires. In particular, the umbral groups G^X are described in detail in §A, and explicit definitions for the mock modular forms $H_g^X(\tau)$ are given in §B.

2 Harmonic Maass forms and Mock modular forms

Here we recall some very basic facts about harmonic Maass forms as developed by Bruinier and Funke [9] (see also [45]).

We begin by briefly recalling the definition of a *harmonic Maass form* of weight $k \in \frac{1}{2}\mathbb{Z}$ and multiplier ν (a generalization of the notion of a Nebentypus). If $\tau = x + iy$ with x and y real, we define the weight k hyperbolic Laplacian by

$$\Delta_k := -y^2\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)+iky\left(\frac{\partial}{\partial x}+i\frac{\partial}{\partial y}\right). \tag{2.1}$$

Suppose Γ is a subgroup of finite index in $SL_2(\mathbb{Z})$ and $k \in \frac{1}{2}\mathbb{Z}$. Then a function $F(\tau)$ which is real-analytic on the upper half of the complex plane is a *harmonic Maass form* of weight k on Γ with multiplier ν if:

(a) The function $F(\tau)$ satisfies the weight k modular transformation,

$$F(\tau)|_k\gamma = \nu(\gamma)F(\tau)$$

for every matrix $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma$, where $F(\tau)|_k\gamma := F(\gamma\tau)(c\tau+d)^{-k}$, and if $k \in \mathbb{Z}+\frac{1}{2}$, the square root is taken to be the principal branch.

(b) We have that $\Delta_k F(\tau) = 0$,

(c) There is a polynomial $P_F(q^{-1})$ and a constant $c > 0$ such that $F(\tau) - P_F(e^{-2\pi i\tau}) = O(e^{-cy})$ as $\tau \to i\infty$. Analogous conditions are required at each cusp of Γ.

We denote the $\mathbb{C}$-vector space of harmonic Maass forms of a given weight k, group Γ and multiplier ν by $H_k(\Gamma, \nu)$. If no multiplier is specified, we will take

$$\nu_0(\gamma) := \left(\left(\frac{c}{d}\right)\sqrt{\left(\frac{-1}{d}\right)}^{\,-1}\right)^{2k},$$

where $\left(\frac{*}{d}\right)$ is the Kronecker symbol.

2.1 Main properties

The Fourier expansion of a harmonic Maass form F (see Proposition 3.2 of [9]) splits into two components. As before, we let $q := e^{2\pi i\tau}$.

Lemma 2.1. *If $F(\tau)$ is a harmonic Maass form of weight $2-k$ for Γ where $\frac{3}{2} \leq k \in \frac{1}{2}\mathbb{Z}$, then*

$$F(\tau) = F^{+}(\tau) + F^{-}(\tau),$$

where F^{+} is the holomorphic part of F, given by

$$F^{+}(\tau) = \sum_{n \gg -\infty} c_F^{+}(n) q^n$$

where the sum admits only finitely many non-zero terms with $n < 0$, and F^{-} is the nonholomorphic part, given by

$$F^{-}(\tau) = \sum_{n<0} c_F^{-}(n) \Gamma(k-1, 4\pi y|n|) q^n.$$

Here $\Gamma(s, z)$ is the upper incomplete gamma function.

The holomorphic part of a harmonic Maass form is called a *mock modular form.* We denote the space of harmonic Maass forms of weight $2-k$ for Γ and multiplier ν by $H_k(\Gamma, \nu)$. Similarly, we denote the corresponding subspace of holomorphic modular forms by $M_k(\Gamma, \nu)$, and the space of cusp forms by $S_k(\Gamma, \nu)$. The differential operator $\xi_w := 2iy^w \overline{\frac{\partial}{\partial \overline{\tau}}}$ (see [9]) defines a surjective map

$$\xi_{2-k} : H_{2-k}(\Gamma, \nu) \to S_k(\Gamma, \overline{\nu})$$

onto the space of weight k cusp forms for the same group but conjugate multiplier. The *shadow* of a Maass form $f(\tau) \in H_{2-k}(\Gamma, \nu)$ is the cusp form $g(\tau) \in S_k(\Gamma, \overline{\nu})$ (defined, for now, only up to scale) such that $\xi_{2-k} f(\tau) = \frac{g}{||g||}$, where $|| \bullet ||$ denotes the usual Petersson norm.

2.2 Holomorphic projection of weight $\frac{1}{2}$ mock modular forms

As noted above, the modular transformations of a weight $\frac{1}{2}$ harmonic Maass form may be simplified by multiplying by its shadow to obtain a weight 2 nonholomorphic modular form. One can use the theory of holomorphic projections to obtain explicit identities relating these nonholomorphic modular forms to classical quasimodular forms. In this way, we may essentially reduce many questions about the coefficients of weight $\frac{1}{2}$ mock modular forms to questions about weight 2 holomorphic modular forms. The following theorem is a special case of a more general theorem due to Mertens (cf. Theorem 6.3 of [42]). See also [41].

Theorem 2.2 (Mertens)**.** *Suppose $g(\tau)$ and $h(\tau)$ are both theta functions of weight $\frac{3}{2}$ contained in $S_{\frac{3}{2}}(\Gamma, \nu_g)$ and $S_{\frac{3}{2}}(\Gamma, \nu_h)$ respectively, with Fourier expansions*

$$g(\tau) : = \sum_{i=1}^{s} \sum_{n \in \mathbb{Z}} n \chi_i(n) q^{n^2},$$

$$h(\tau) := \sum_{j=1}^{t} \sum_{n \in \mathbb{Z}} n \psi_j(n) q^{n^2},$$

where each χ_i *and* ψ_i *is a Dirichlet character. Moreover, suppose* $h(\tau)$ *is the shadow of a weight* $\frac{1}{2}$ *harmonic Maass form* $f(\tau) \in H_{\frac{1}{2}}(\Gamma, \overline{\nu_h})$*. Define the function*

$$D^{f,g}(\tau) := 2 \sum_{r=1}^{\infty} \sum_{\chi_i, \psi_j} \sum_{\substack{m,n \in \mathbb{Z}^+ \\ m^2 - n^2 = r}} \chi_i(m) \overline{\psi_j(n)} (m-n) q^r.$$

If $f(\tau)g(\tau)$ *has no singularity at any cusp, then* $f^+(\tau)g(\tau) + D^{f,g}(\tau)$ *is a weight* 2 *quasimodular form. In other words, it lies in the space* $\mathbb{C}E_2(\tau) \oplus M_2(\Gamma, \nu_g \overline{\nu_h})$*, where* $E_2(\tau)$ *is the quasimodular Eisenstein series* $E_2(\tau) := 1 - 24 \sum_{n \geq 1} \frac{nq^n}{1-q^n}$.

Two Remarks.
1) These identities give recurrence relations for the weight $\frac{1}{2}$ mock modular form f^+ in terms of the weight 2 quasimodular form which equals $f^+(\tau)g(\tau) + D^{f,g}(\tau)$. The example after Theorem 1.2 for Ramanujan's third order mock theta function f is an explicit example of such a relation.

2) Theorem 2.2 extends to vector-valued mock modular forms in a natural way.

Proof of Theorem 1.2. Fix a Niemeier lattice and its root system X, and let $M = m^X$ denote its Coxeter number. Each $H^X_{g,r}(\tau)$ is the holomorphic part of a weight $\frac{1}{2}$ harmonic Maass form $\widehat{H}^X_{g,r}(\tau)$. To simplify the exposition in the following section, we will emphasize the case that the root system X is of pure A-type. If the root system X is of pure A-type, the shadow function $S^X_{g,r}(\tau)$ is given by $\hat{\chi}^{X_A}_{g,r} S_{M,r}(\tau)$ (see §B.2), where

$$S_{M,r}(\tau) = \sum_{\substack{n \in \mathbb{Z} \\ n \equiv r \pmod{2M}}} n\, q^{\frac{n^2}{4M}},$$

and $\hat{\chi}^{X_A}_{g,r} = \chi^{X_A}_g$ or $\bar{\chi}^{X_A}_g$ depending on the parity of r is the twisted Euler character given in the appropriate table in §A.3, a character of G^X. (If X is not of pure A-type, then the shadow function $S^X_{g,r}(\tau)$ is a linear combination of similar functions as described in §B.2.)

Given X and g, the symbol $n_g|h_g$ given in the corresponding table in §A.3 defines the modularity for the vector-valued function $(\widehat{H}^X_{g,r}(\tau))$. In particular, if the shadow $(S^X_{g,r}(\tau))$ is nonzero, and if for $\gamma \in \Gamma_0(n_g)$ we have that

$$(S^X_{g,r}(\tau))|_{3/2}\gamma = \sigma_{g,\gamma}(S^X_{g,r}(\tau)),$$

then

$$(\widehat{H}^X_{g,r}(\tau))|_{1/2}\gamma = \overline{\sigma_{g,\gamma}}(\widehat{H}^X_{g,r}(\tau)).$$

Here, for $\gamma \in \Gamma_0(n_g)$, we have $\sigma_{g,\gamma} = \nu_g(\gamma)\sigma_{e,\gamma}$ where $\nu_g(\gamma)$ is a multiplier which is trivial on $\Gamma_0(n_g h_g)$. This identity holds even in the case that the shadow $S^X_{g,r}$ vanishes.

The vector-valued function $(H^X_{g,r}(\tau))$ has poles only at the infinite cusp of $\Gamma_0(n_g)$, and only at the component $H^X_{g,r}(\tau)$ where $r = 1$ if X has pure A-type, or at components where $r^2 \equiv 1 \pmod{4M}$ otherwise. These poles may only have order $\frac{1}{4M}$. This implies that the function $(\widehat{H}^X_{g,r}(\tau) S^X_{g,r}(\tau))$ has no pole at any cusp, and is therefore a candidate for an application of Theorem 2.2.

The modular transformation of $S_{M,r}(\tau)$ implies that

$$(\sigma_{e,S})^2 = (\sigma_{e,T})^{4M} = \mathbf{I}$$

where $S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, and $\mathbf{I}$ is the identity matrix. Therefore $S^X_{M,r}(\tau)$, viewed as a scalar-valued modular function, is modular on $\Gamma(4M)$, and so $(\widehat{H}^X_{g,r}(\tau) S^X_{g,r}(\tau))$ is a weight 2 nonholomorphic scalar-valued modular form for the group $\Gamma(4M) \cap \Gamma_0(n_g)$ with trivial multiplier.

Applying Theorem 2.2, we obtain a function $F^X_{g,r}(\tau)$—call it the holomorphic projection of $\widehat{H^X_{g,r}}(\tau) S^X_{e,r}(\tau)$—which is a weight 2 quasimodular form on $\Gamma(4M) \cap \Gamma_0(n_g)$. In the case that $S^X_{g,r}(\tau)$ is zero, we substitute $S^X_{e,r}(\tau)$ in its place to obtain a function $\widetilde{F}^X_{g,r}(\tau) = H^X_{g,r}(\tau) S^X_{e,r}(\tau)$ which is a weight 2 holomorphic scalar-valued modular form for the group $\Gamma(4M) \cap \Gamma_0(n_g)$ with multiplier ν_g (alternatively, modular for the group $\Gamma(4M) \cap \Gamma_0(n_g h_g)$ with trivial multiplier).

The function $F^X_{g,r}(\tau)$ may be determined explicitly as the sum of Eisenstein series and cusp forms on $\Gamma(4M) \cap \Gamma_0(n_g h_g)$ using the standard arguments from the theory of holomorphic modular forms (i.e. the “first few” coefficients determine such a form). Therefore, we have the identity

$$F^X_{g,r}(\tau) = H^X_{g,r}(\tau) \cdot S^X_{g,r}(\tau) + D^X_{g,r}(\tau), \tag{2.2}$$

where the function $D^X_{g,r}(\tau)$ is the correction term arising in Theorem 2.2. If X has pure A-type, then

$$D^X_{g,r}(\tau) = (\hat{\chi}^{X_A}_{g,r})^2 \sum_{N=1}^{\infty} \sum_{\substack{m,n \in \mathbb{Z}_+ \\ m^2 - n^2 = N}} \phi_r(m)\phi_r(n)(m-n) q^{\frac{N}{4M}}, \tag{2.3}$$

where

$$\phi_r(\ell) = \begin{cases} \pm 1 & \text{if } \ell \equiv \pm r \pmod{2M} \\ 0 & \text{otherwise.} \end{cases}$$

Suppose $H^X_{g,r}(\tau) = \sum_{n=0}^{\infty} A^X_{g,r}(n) q^{n - \frac{D}{4M}}$ where $0 < D < 4M$ and $D \equiv r^2 \pmod{4M}$, and $F^X_{g,r}(\tau) = \sum_{N=0}^{\infty} B^X_{g,r}(n) q^n$. Then by Theorem 2.2, we find that

$$B^X_{g,r}(N) = \hat{\chi}^{X_A}_{g,r} \sum_{\substack{m \in \mathbb{Z} \\ m \equiv r \pmod{2M}}} m \cdot A^X_{g,r}\left(N + \frac{D - m^2}{4M}\right) + (\hat{\chi}^{X_A}_{g,r})^2 \sum_{\substack{m,n \in \mathbb{Z}^+ \\ m^2 - n^2 = N}} \phi_r(m)\phi_r(n)(m-n). \tag{2.4}$$

The function $F^X_{g,r}(\tau)$ may be found in the following manner. Using the explicit prescriptions for $H^X_{g,r}(\tau)$ given in §B.3 and (2.2) above, we may calculate the first several coefficients of each component. The Eisenstein component is determined by the constant terms at cusps. Since $D^X_{g,r}(\tau)$ (and the corresponding correction terms at other cusps) has no constant term, these are the same as the constant terms of $\widehat{H^X_{g,r}}(\tau) S^X_{g,r}(\tau)$, which are determined by the poles of $\widehat{H^X_{g,r}}$. Call this Eisenstein component $E^X_{g,r}(\tau)$. The cuspidal component can be found by matching the initial coefficients of $F^X_{g,r}(\tau) - E^X_{g,r}(\tau)$.

Once the coefficients $B^X_{g,r}(n)$ are known, equation (2.4) provides a recursion relation which may be used to calculate the coefficients of $H^X_{g,r}(\tau)$. If the shadows $S^X_{g,r}(\tau)$ are zero, then we may apply a similar procedure in order to determine $\widetilde{F}^X_{g,r}(\tau)$. For example, suppose $\widetilde{F}^X_{g,r}(\tau) = \sum_{N=0}^{\infty} \widetilde{B}^X_{g,r}(n)q^n$, and X has pure A-type. Then we find that the coefficients $\widetilde{B}^X_{g,r}(N)$ satisfy

$$\widetilde{B}^X_{g,r}(N) = \hat{\chi}^{X_A}_{g,r} \sum_{\substack{m\in\mathbb{Z} \\ m\equiv r \pmod{2M}}} m \cdot A^X_{g,r}\left(N + \frac{D-m^2}{4M}\right) \tag{2.5}$$

Proceeding in this way we obtain the claimed results. □

3 Proof of Theorem 1.1

Here we prove Theorem 1.1. The idea is as follows. For each Niemeier root system X we begin with the vector-valued mock modular forms $(H^X_g(\tau))$ for $g \in G^X$. We use their q-expansions to solve for the q-series whose coefficients are the alleged multiplicities of the irreducible components of the alleged infinite-dimensional G^X-module

$$\check{K}^X = \bigoplus_{r \pmod{2m}} \bigoplus_{\substack{D\in\mathbb{Z},\, D\le 0, \\ D=r^2 \pmod{4m}}} \check{K}^X_{r,-D/4m}.$$

These q-series turn out to be mock modular forms. The proof requires that we establish that these mock modular forms have non-negative integer coefficients.

Proof of Theorem 1.1. As in the previous section, we fix a root system X and set $M := m^X$, and we emphasize the case when X is of pure A-type.

The umbral moonshine conjecture asserts that

$$H^X_{g,r}(\tau) = \sum_{n=0}^{\infty}\sum_{\chi} m^X_{\chi,r}(n)\chi(g)q^{n-\frac{r^2}{4M}} \tag{3.1}$$

where the second sum is over the irreducible characters of G^X. Here we have rewritten the traces of the graded components $\check{K}^X_{r,n-r^2/4M}$ in 1.4 in terms of the values of the irreducible characters of G^X, where the $m^X_{\chi,r}(n)$ are the corresponding multiplicities. Naturally, if such a $\check{K}^X$ exists, these multiplicities must be non-negative integers for $n > 0$. Similarly, if the mock modular forms $H^X_{g,r}(\tau)$ can be expressed as in 3.1 with $m^X_{\chi,r}(n)$ non-negative integers, then we may construct the umbral moonshine module $\check{K}^X$ explicitly with $\check{K}^X_{r,n-r^2/4M}$ defined as the direct sum of irreducible components with the given multiplicities $m^X_{\chi,r}(n)$.

Let

$$H^X_{\chi,r}(\tau) := \frac{1}{|G^X|}\sum_{g} \overline{\chi(g)}H^X_{g,r}(\tau). \tag{3.2}$$

It turns out that the coefficients of $H^X_{\chi,r}(\tau)$ are precisely the multiplicities $m^X_{\chi,r}(n)$ required so that 3.1 holds: if

$$H^X_{\chi,r}(\tau) = \sum_{n=0}^{\infty} m^X_{\chi,r}(n) q^{n-\frac{r^2}{4M}}, \tag{3.3}$$

then

$$H^X_{g,r}(\tau) = \sum_{n=0}^{\infty} \sum_{\chi} m^X_{\chi,r}(n)\chi(g) q^{n-\frac{r^2}{4M}}.$$

Thus the umbral moonshine conjecture is true if and only if the Fourier coefficients of $H^X_{\chi,r}(\tau)$ are non-negative integers.

To see this fact, we recall the orthogonality of characters. For irreducible characters χ_i and χ_j,

$$\frac{1}{|G^X|} \sum_{g\in G^X} \overline{\chi_i(g)}\chi_j(g) = \begin{cases} 1 & \text{if } \chi_i = \chi_j, \\ 0 & \text{otherwise.} \end{cases} \tag{3.4}$$

We also have the relation for g and $h \in G^X$,

$$\sum_{\chi} \overline{\chi_i(g)}\chi_i(h) = \begin{cases} |C_{G^X}(g)| & \text{if } g \text{ and } h \text{ are conjugate,} \\ 0 & \text{otherwise.} \end{cases} \tag{3.5}$$

Here $|C_{G^X}(g)|$ is the order of the centralizer of g in G^X. Since the order of the centralizer times the order of the conjugacy class of an element is the order of the group, (3.2) and (3.5) together imply the relation

$$H^X_{g,r}(\tau) = \sum_{\chi} \chi(g) H^X_{\chi,r}(\tau),$$

which in turn implies 3.3.

We have reduced the theorem to proving that the coefficients of certain weight $\frac{1}{2}$ mock modular forms are all non-negative integers. For holomorphic modular forms we may answer questions of this type by making use of Sturm's theorem [49] (see also Theorem 2.58 of [44]). This theorem provides a bound B associated to a space of modular forms such that if the first B coefficients of a modular form $f(\tau)$ are integral, then all of the coefficients of $f(\tau)$ are integral. This bound reduces many questions about the Fourier coefficients of modular forms to finite calculations.

Sturm's theorem relies on the finite dimensionality of certain spaces of modular forms, and so it can not be applied directly to spaces of mock modular forms. However, by making use of holomorphic projection we can adapt Sturm's theorem to this setting.

Let $\widehat{H^X_{\chi,r}}(\tau)$ be defined as above. Recall that the transformation matrix for the vector-valued function $\widehat{H^X_{g,r}}(\tau))$ is $\overline{\sigma_{g,\gamma}}$, the conjugate of the transformation matrix for $(S^X_{e,r}(\tau))$ when $\gamma \in \Gamma_0(n_g h_g)$, and $\sigma_{g,\gamma}$ is the identity for $\gamma \in \Gamma(4M)$. Therefore if

$$N^X_{\chi} := \mathrm{lcm}\{n_g h_g \mid g \in G, \chi(g) \neq 0\},$$

then the scalar-valued functions $\widehat{H^X_{\chi,r}}(\tau)$ are modular on $\Gamma(4M) \cap \Gamma_0(N^X_{\chi})$.

Let

$$A_{\chi,r}(\tau) := H^X_{\chi,r}(\tau) S^X_{e,1}(\tau),$$

and let $\tilde{A}_{\chi,r}(\tau)$ be the holomorphic projection of $A_{\chi,r}(\tau)$. Suppose that $H^X_{\chi,r}(\tau)$ has integral coefficients up to some bound B. Formulas for the shadow functions (cf. §B.2) show that the leading coefficient of $S^X_{e,1}(\tau)$ is 1 and has integral coefficients. This implies that the function

$$A_{\chi,r}(\tau) := H^X_{\chi,r}(\tau) S^X_{e,1}(\tau)$$

also has integral coefficients up to the bound B. The shadow of $H^X_{\chi,r}(\tau)$ is given by

$$S^X_{\chi,r}(\tau) := \frac{1}{|G^X|} \sum_g \overline{\chi(g)} S^X_{g,r}(\tau).$$

If X is pure A-type, then $S^X_{g,r}(\tau) = \chi^{X_A}_{g,r} S_{M,r}(\tau) = (\chi'(g) + \chi''(g)) S_{M,r}(\tau)$ for some irreducible characters χ' and χ'', according to §A.3 and §B.2. Therefore,

$$S^X_{\chi,r}(\tau) = \begin{cases} S_{M,r}(\tau) & \text{if } \chi = \chi' \text{ or } \chi'', \\ 0 & \text{otherwise.} \end{cases}$$

When X is not of pure A-type the shadow is some sum of such functions, but in every case has integer coefficients, and so, applying Theorem 2.2 to $A_{\chi,r}(\tau)$, we find that $\tilde{A}_{\chi,r}(\tau)$ also has integer coefficients up to the bound B. In particular, since $\tilde{A}_{\chi,r}(\tau)$ is modular on $\Gamma(4M) \cap \Gamma_0(N^X_\chi)$, then if B is at least the Sturm bound for this group we have that every coefficient of $\tilde{A}_{\chi,r}(\tau)$ is integral. Since the leading coefficient of $S^X_{e,1}(\tau)$ is 1, we may reverse this argument and obtain that every coefficient of $H^X_{\chi,r}(\tau)$ is integral. Therefore, in order to check that $H^X_{\chi,r}(\tau)$ has only integer coefficients, it suffices to check up to the Sturm bound for $\Gamma(4M) \cap \Gamma_0(N_\chi)$. These calculations were carried out using the `sage` mathematical software [47].

The calculations and argument given above shows that the multiplicities $m^X_{\chi,r}(n)$ are all integers. To complete the proof, it suffices to check that they are also are non-negative. The proof of this claim follows easily by modifying step-by-step the argument in Gannon's proof of non-negativity in the M_{24} case [37] (i.e. $X = A_1^{24}$). Here we describe how this is done.

Expressions for the alleged McKay-Thompson series $H^X_{g,r}(\tau)$ in terms of Rademacher sums and unary theta functions are given in §B.4. Exact formulas are known for all the coefficients of Rademacher sums because they are defined by averaging the special function $\mathrm{r}^{[\alpha]}_{1/2}(\gamma, \tau)$ (see (B.114)) over cosets of a specific modular group modulo Γ_∞, the subgroup of translations. Therefore, Rademacher sums are standard Maass-Poincaré series, and as a result we have formulas for each of their coefficients as convergent infinite sums of Kloosterman-type sums weighted by values of the $I_{1/2}$ modified Bessel function. (For example, see [8] or [53] for the general theory, and [12] for the specific case that $X = A_1^{24}$.) More importantly, this means also that the generating function for the multiplicities $m^X_{\chi,r}(n)$ is a weight $\frac{1}{2}$ harmonic Maass form, which in turn means that exact formulas (modulo the unary theta functions) are also available in similar terms. For positive integers n, this then means that (cf. Theorem 1.1 of [8])

$$m^X_{\chi,r}(n) = \sum_\rho \sum_{m<0} \frac{a^X_\rho(m)}{n^{\frac{1}{4}}} \sum_{c=1}^\infty \frac{K^X_\rho(m,n,c)}{c} \cdot \mathbb{I}^X \left(\frac{4\pi\sqrt{|nm|}}{c} \right), \tag{3.6}$$

where the sums are over the cusps ρ of the group $\Gamma_0(N^X_g)$, and finitely many explicit negative rational numbers m. The constants $a^X_\rho(m)$ are essentially the coefficients which describe the generating function in terms of Maass-Poincaré series. Here $\mathbb{I}$ is a suitable normalization and change of variable for the standard $I_{1/2}$ modified Bessel-function.

The Kloosterman-type sums $K_\rho^X(m,n,c)$ are well known to be related to Salié-type sums (for example see Proposition 5 of [40]). These Salié-type sums are of the form

$$S_\rho^X(m,n,c) = \sum_{\substack{x \pmod{c} \\ x^2 \equiv -D(m,n) \pmod{c}}} \epsilon_\rho^X(m,n) \cdot e\left(\frac{\beta^X x}{c}\right),$$

where $\epsilon_\rho^X(m,n)$ is a root of unity, $-D(m,n)$ is a discriminant of a positive definite binary quadratic form, and β^X is a nonzero positive rational number.

These Salié sums may then be estimated using the equidistribution of CM points with discriminant $-D(m,n)$. This process was first introduced by Hooley [38], and it was first applied to the coefficients of weight $\frac{1}{2}$ mock modular forms by Bringmann and Ono [7]. Gannon explains how to make effective the estimates for sums of this shape in §4 of [37], thereby reducing the proof of the M_{24} case of umbral moonshine to a finite calculation. In particular, in equations (4.6-4.10) of [37] Gannon shows how to bound coefficients of the form (3.6) in terms of the Selberg–Kloosterman zeta function, which is bounded in turn in his proof of Theorem 3 of [37]. We follow Gannon's proof *mutatis mutandis*. We find, for most root systems, that the coefficients of each multiplicity generating function are positive beyond the 390th coefficient. In the worst case, for the root system $X = E_8^3$, we find that the coefficients are positive beyond the 1780th coefficient. Moreover, the coefficients exhibit subexponential growth. A finite computer calculation in `sage` has verified the non-negativity of the finitely many remaining coefficients. ☐

Remark. It turns out that the estimates required for proving non-negativity are the worst for the $X = E_8^3$ case which required 1780 coefficients.

A The Umbral Groups

In this section we present the facts about the umbral groups that we have used in establishing the main results of this paper. We recall (from [16]) their construction in terms of Niemeier root systems in §A.1, and we reproduce their character tables (appearing also in [16]) in §A.2. Note that we use the abbreviations $a_n := \sqrt{-n}$ and $b_n := (-1+\sqrt{-n})/2$ in the tables of §A.2.

The root system description of the umbral groups (cf. §A.1) gives rise to certain characters called *twisted Euler characters* which we recall (from [16]) in §A.3. The data appearing in §A.3 plays an important role in §B.2, where we use it to describe the shadows S_g^X of the umbral McKay-Thompson series H_g^X explicitly.

A.1 Construction

As mentioned in §1, there are exactly 24 self-dual even positive-definite lattices of rank 24 up to isomorphism, according to the classification of Niemeier [43] (cf. also [19, 52]). Such a lattice L is determined up to isomorphism by its *root system* $L_2 := \{\alpha \in L \mid \langle \alpha, \alpha \rangle = 2\}$. The unique example without roots is the Leech lattice. We refer to the remaining 23 as the *Niemeier lattices*, and we call a root system X a *Niemeier root system* if it occurs as the root system of a Niemeier lattice.

The simple components of Niemeier root systems are root systems of ADE type, and it turns out that the simple components of a Niemeier root system X all have the same Coxeter number. Define m^X to be the Coxeter number of any simple component of X, and call this the *Coxeter number* of X.

For X a Niemeier root system write N^X for the corresponding Niemeier lattice. The *umbral group* attached to X is defined by setting

$$G^X := \mathrm{Aut}(N^X)/W^X \tag{A.1}$$

where W^X is the normal subgroup of $\mathrm{Aut}(N^X)$ generated by reflections in root vectors.

Observe that G^X acts as permutations on the simple components of X. In general this action is not faithful, so define $\overline{G}^X$ to be the quotient of G^X by its kernel. It turns out that the level of the mock modular form H_g^X attached to $g \in G^X$ is given by the order, denoted n_g, of the image of g in $\bar{G}^X$. (Cf. §A.3 for the values n_g.)

The Niemeier root systems and their corresponding umbral groups are described in Table 1. The root systems are given in terms of their simple components of ADE type. Here $D_{10}E_7^2$, for example, means the direct sum of one copy of the D_{10} root system and two copies of the E_7 root system. The symbol ℓ is called the *lambency* of X, and the Coxeter number m^X appears as the first summand of ℓ.

In the descriptions of the umbral groups G^X, and their permutation group quotients $\bar{G}^X$, we write M_{24} and M_{12} for the sporadic simple groups of Mathieu which act quintuply transitively on 24 and 12 points, respectively. (Cf. e.g. [21].) We write $GL_n(q)$ for the general linear group of a vector space of dimension n over a field with q elements, and $SL_n(q)$ is the subgroup of linear transformations with determinant 1, &c. The symbols $AGL_3(2)$ denote the *affine general linear group*, obtained by adjoining translations to $GL_3(2)$. We write Dih_n for the dihedral group of order $2n$, and Sym_n denotes the symmetric group on n symbols. We use n as a shorthand for a cyclic group of order n.

Table 1: The Umbral Groups

X	A_1^{24}	A_2^{12}	A_3^8	A_4^6	$A_5^4D_4$	A_6^4	$A_7^2D_5^2$
ℓ	2	3	4	5	6	7	8
G^X	M_{24}	$2.M_{12}$	$2.AGL_3(2)$	$GL_2(5)/2$	$GL_2(3)$	$SL_2(3)$	Dih_4
$\bar{G}^X$	M_{24}	M_{12}	$AGL_3(2)$	$PGL_2(5)$	$PGL_2(3)$	$PSL_2(3)$	2^2

X	A_8^3	$A_9^2D_6$	$A_{11}D_7E_6$	A_{12}^2	$A_{15}D_9$	$A_{17}E_7$	A_{24}
ℓ	9	10	12	13	16	18	25
G^X	Dih_6	4	2	4	2	2	2
$\bar{G}^X$	Sym_3	2	1	2	1	1	1

X	D_4^6	D_6^4	D_8^3	$D_{10}E_7^2$	D_{12}^2	$D_{16}E_8$	D_{24}
ℓ	6+3	10+5	14+7	18+9	22+11	30+15	46+23
G^X	$3.Sym_6$	Sym_4	Sym_3	2	2	1	1
$\bar{G}^X$	Sym_6	Sym_4	Sym_3	2	2	1	1

X	E_6^4	E_8^3
ℓ	12+4	30+6,10,15
G^X	$GL_2(3)$	Sym_3
$\bar{G}^X$	$PGL_2(3)$	Sym_3

We also use the notational convention of writing $A.B$ to denote the middle term in a short exact sequence $1 \to A \to A.B \to B \to 1$. This introduces some ambiguity which is nonetheless easily navigated in practice. For example, $2.M_{12}$ is the unique (up to isomorphism) double cover of M_{12} which is not $2 \times M_{12}$. The group $AGL_3(2)$ naturally embeds in $GL_4(2)$, which in turn admits a unique (up to isomorphism) double cover $2.GL_4(2)$ which is not a direct product. The group we denote $2.AGL_3(2)$ is the preimage of $AGL_3(2) < GL_4(2)$ in $2.GL_4(2)$ under the natural projection.

A.3 Twisted Euler Characters

In this section we reproduce certain characters—the *twisted Euler characters*—which are attached to each group G^X, via its action on the root system X. (Their construction is described in detail in §2.4 of [16].)

To interpret the tables, write X_A for the (possibly empty) union of type A components of X, and interpret X_D and X_E similarly, so that if $m = m^X$ Then $X = A_{m-1}^d$ for some d, and $X = X_A \cup X_D \cup X_E$, for example. Then $g \mapsto \bar{\chi}_g^{X_A}$ denotes the character of the permutation representation attached to the action of $\bar{G}^X$ on the simple components of X_A. The characters $g \mapsto \bar{\chi}_g^{X_D}$ and $g \mapsto \bar{\chi}_g^{X_E}$ are defined similarly. The characters $\chi_g^{X_A}$, $\chi_g^{X_D}$, $\chi_g^{X_E}$ and $\check{\chi}_g^{X_D}$ incorporate outer automorphisms of simple root systems induced by the action G^X on X. We refer to §2.4 of [16] for full details of the construction. For the purposes of this work, it suffices to have the explicit descriptions in the tables in this section. The twisted Euler characters presented here will be used to specify the umbral shadow functions in §B.2.

The twisted Euler character tables also attach integers n_g and h_g to each $g \in G^X$. By definition, n_g is the order of the image of $g \in G^X$ in $\bar{G}^X$ (cf. §A.1). The integer h_g may be defined by setting $h_g := N_g/n_g$ where N_g is the product of the shortest and longest cycle lengths appearing in the cycle shape attached to g by the action of G^X on a (suitable) set of simple roots for X.

B The Umbral McKay-Thompson Series

In this section we describe the umbral McKay-Thompson series in complete detail. In particular, we present explicit formulas for all the McKay-Thompson series attached to elements of the umbral groups by umbral moonshine in §B.3. Most of these expressions appeared first in [15,16], but some appear for the first time in this work.

In order to facilitate explicit formulations we recall certain standard functions in §B.1. We then, using the twisted Euler characters of §A.3, explicitly describe the shadow functions of umbral moonshine in §B.2. The umbral McKay–Thompson series defined in §B.3 may also be described in terms of Rademacher sums, according to the results of [17]. We present this description in §B.4.

B.1 Special Functions

Throughout this section we assume $q := e^{2\pi i\tau}$, and $u := e^{2\pi iz}$, where $\tau, z \in \mathbb{C}$ with Im $\tau > 0$. The Dedekind eta function is $\eta(\tau) := q^{1/24}\prod_{n>0}(1-q^n)$, where . Write $\Lambda_M(\tau)$ for the function

$$\Lambda_M(\tau) := Mq\frac{\mathrm{d}}{\mathrm{d}q}\left(\log\frac{\eta(M\tau)}{\eta(\tau)}\right) = \frac{M(M-1)}{24} + M\sum_{k>0}\sum_{d|k} d\left(q^k - Mq^{Mk}\right),$$

which is a modular form of weight two for $\Gamma_0(N)$ if $M|N$.

Define the Jacobi theta function $\theta_1(\tau, z)$ by setting

$$\theta_1(\tau, z) := iq^{1/8}u^{-1/2}\sum_{n\in\mathbb{Z}}(-1)^n u^n q^{n(n-1)/2}. \tag{B.1}$$

According to the Jacobi triple product identity we have

$$\theta_1(\tau, z) = -iq^{1/8}u^{1/2}\prod_{n>0}(1-u^{-1}q^{n-1})(1-uq^n)(1-q^n). \tag{B.2}$$

The other Jacobi theta functions are

$$\begin{aligned}
\theta_2(\tau, z) &:= q^{1/8}u^{1/2}\prod_{n>0}(1+u^{-1}q^{n-1})(1+uq^n)(1-q^n),\\
\theta_3(\tau, z) &:= \prod_{n>0}(1+u^{-1}q^{n-1/2})(1+uq^{n-1/2})(1-q^n),\\
\theta_4(\tau, z) &:= \prod_{n>0}(1-u^{-1}q^{n-1/2})(1-uq^{n-1/2})(1-q^n).
\end{aligned} \tag{B.3}$$

Define $\Psi_{1,1}$ and $\Psi_{1,-1/2}$ by setting

$$\begin{aligned}
\Psi_{1,1}(\tau, z) &:= -i\frac{\theta_1(\tau, 2z)\eta(\tau)^3}{\theta_1(\tau, z)^2},\\
\Psi_{1,-1/2}(\tau, z) &:= -i\frac{\eta(\tau)^3}{\theta_1(\tau, z)}.
\end{aligned} \tag{B.4}$$

These are meromorphic Jacobi forms of weight one, with indexes 1 and $-1/2$, respectively. Here, the term meromorphic refers to the presence of simple poles in the functions $z \mapsto \Psi_{1,*}(\tau, z)$, for fixed $\tau \in \mathbb{H}$, at lattice points $z \in \mathbb{Z}\tau + \mathbb{Z}$. (Cf. §8 of [22].)

From §5 of [29] we recall the *index m theta functions*, for $m \in \mathbb{Z}$, defined by setting

$$\theta_{m,r}(\tau,z) := \sum_{k\in\mathbb{Z}} u^{2mk+r} q^{(2mk+r)^2/4m}, \tag{B.5}$$

where $r \in \mathbb{Z}$. Evidently, $\theta_{m,r}$ only depends on $r \mod 2m$. We set $S_{m,r}(\tau) := \frac{1}{2\pi i}\, \partial_z \theta_{m,r}(\tau,z)\big|_{z=0}$, so that

$$S_{m,r}(\tau) = \sum_{k\in\mathbb{Z}} (2mk+r) q^{(2mk+r)^2/4m}. \tag{B.6}$$

For a m a positive integer define

$$\mu_{m,0}(\tau,z) = \sum_{k\in\mathbb{Z}} u^{2km} q^{mk^2} \frac{uq^k+1}{uq^k-1} = \frac{u+1}{u-1} + O(q), \tag{B.7}$$

and observe that we recover $\Psi_{1,1}$ upon specializing (B.7) to $m = 1$. Observe also that

$$\mu_{m,0}(\tau,z+1/2) = \sum_{k\in\mathbb{Z}} u^{2km} q^{mk^2} \frac{uq^k-1}{uq^k+1} = \frac{u-1}{u+1} + O(q). \tag{B.8}$$

Define the even and odd parts of $\mu_{m,0}$ by setting

$$\mu^k_{m,0}(\tau,z) := \frac{1}{2}(\mu_{m,0}(\tau,z) + (-1)^k \mu_{m,0}(\tau,z+1/2)) \tag{B.9}$$

for $k \mod 2$.

For $m, r \in \mathbb{Z} + \frac{1}{2}$ with $m > 0$ define *half-integral index theta functions*

$$\theta_{m,r}(\tau,z) := \sum_{k\in\mathbb{Z}} e(mk + r/2) u^{2mk+r} q^{(2mk+r)^2/4m}, \tag{B.10}$$

and define also $S_{m,r}(\tau) := \frac{1}{2\pi i} \partial_z \theta_{m,r}(\tau,z)|_{z=0}$, so that

$$S_{m,r}(\tau) = \sum_{k\in\mathbb{Z}} e(mk + r/2)(2mk+r) q^{(2mk+r)^2/4m}. \tag{B.11}$$

As in the integral index case, $\theta_{m,r}$ depends only on $r \mod 2m$. We recover $-\theta_1$ upon specializing $\theta_{m,r}$ to $m = r = 1/2$.

For $m \in \mathbb{Z} + 1/2$, $m > 0$, define

$$\mu_{m,0}(\tau,z) := i \sum_{k\in\mathbb{Z}} (-1)^k u^{2mk+1/2} q^{mk^2+k/2} \frac{1}{1-uq^k} = \frac{-iu^{1/2}}{y-1} + O(q). \tag{B.12}$$

Given $\alpha \in \mathbb{Q}$ write $[\alpha]$ for the operator on q-series (in rational, possibility negative powers of q) that eliminates exponents not contained in $\mathbb{Z} + \alpha$, so that if $f = \sum_{\beta\in\mathbb{Q}} c(\beta) q^\beta$ then

$$[\alpha]f := \sum_{n\in\mathbb{Z}} c(n+\alpha) q^{n+\alpha} \tag{B.13}$$

B.2 Shadows

Let X be a Niemeier root system and let $m = m^X$ be the Coxeter number of X. For $g \in G^X$ we define the associated *shadow function* $S^X_g = (S^X_{g,r})$ by setting

$$S^X_g := S^{X_A}_g + S^{X_D}_g + S^{X_E}_g \tag{B.14}$$

where the $S^{X_A}_g$, &c., are defined in the following way, in terms of the twisted Euler characters $\chi^{X_A}_g$, &c. given in §A.3, and the unary theta series $S_{m,r}$ (cf. (B.6)).

Note that if $m = m^X$ then $S^X_{g,r} = S^X_{g,r+2m} = -S^X_{g,-r}$ for all $g \in G^X$, so we need specify the $S^{X_A}_{g,r}$, &c., only for $0 < r < m$.

If $X_A = \emptyset$ then $S^{X_A}_g := 0$. Otherwise, we define $S^{X_A}_{g,r}$ for $0 < r < m$ by setting

$$S^{X_A}_{g,r} := \begin{cases} \chi^{X_A}_g S_{m,r} & \text{if } r = 0 \mod 2, \\ \bar{\chi}^{X_A}_g S_{m,r} & \text{if } r = 1 \mod 2. \end{cases} \tag{B.15}$$

If $X_D = \emptyset$ then $S^{X_D}_g := 0$. If $X_D \neq \emptyset$ then m is even and $m \geq 6$. If $m = 6$ then set

$$S^{X_D}_{g,r} := \begin{cases} 0 & \text{if } r = 0 \mod 2, \\ \bar{\chi}^{X_D}_g S_{6,r} + \chi^{X_D}_g S_{6,6-r} & \text{if } r = 1,5 \mod 6, \\ \check{\chi}^{X_D}_g S_{6,r} & \text{if } r = 3 \mod 6. \end{cases} \tag{B.16}$$

If $m > 6$ and $m = 2 \mod 4$ then set

$$S^{X_D}_{g,r} := \begin{cases} 0 & \text{if } r = 0 \mod 2, \\ \bar{\chi}^{X_D}_g S_{m,r} + \chi^{X_D}_g S_{m,m-r} & \text{if } r = 1 \mod 2. \end{cases} \tag{B.17}$$

If $m > 6$ and $m = 0 \mod 4$ then set

$$S^{X_D}_{g,r} := \begin{cases} \chi^{X_D}_g S_{m,m-r} & \text{if } r = 0 \mod 2, \\ \bar{\chi}^{X_D}_g S_{m,r} & \text{if } r = 1 \mod 2. \end{cases} \tag{B.18}$$

If $X_E = \emptyset$ then $S^{X_E}_g := 0$. Otherwise, m is 12 or 18 or 30. In case $m = 12$ define $S^{X_E}_{g,r}$ for $0 < r < 12$ by setting

$$S^{X_E}_{g,r} = \begin{cases} \bar{\chi}^{X_E}_g (S_{12,1} + S_{12,7}) & \text{if } r \in \{1,7\}, \\ \bar{\chi}^{X_E}_g (S_{12,5} + S_{12,11}) & \text{if } r \in \{5,11\}, \\ \chi^{X_E}_g (S_{12,4} + S_{12,8}) & \text{if } r \in \{4,8\}, \\ 0 & \text{else.} \end{cases} \tag{B.19}$$

In case $m = 18$ define $S^{X_E}_{g,r}$ for $0 < r < 18$ by setting

$$S^{X_E}_{g,r} = \begin{cases} \bar{\chi}^{X_E}_g (S_{18,r} + S_{18,18-r}) & \text{if } r \in \{1,5,7,11,13,17\}, \\ \bar{\chi}^{X_E}_g S_{18,9} & \text{if } r \in \{3,15\}, \\ \bar{\chi}^{X_E}_g (S_{18,3} + S_{18,9} + S_{18,15}) & \text{if } r = 9, \\ 0 & \text{else.} \end{cases} \tag{B.20}$$

In case $m = 30$ define $S^{X_E}_{g,r}$ for $0 < r < 30$ by setting

$$S^{X_E}_{g,r} = \begin{cases} \bar{\chi}^{X_E}_g (S_{30,1} + S_{30,11} + S_{30,19} + S_{30,29}) & \text{if } r \in \{1, 11, 19, 29\}, \\ \bar{\chi}^{X_E}_g (S_{30,7} + S_{30,13} + S_{30,17} + S_{30,23}) & \text{if } r \in \{7, 13, 17, 23\}, \\ 0 & \text{else.} \end{cases} \tag{B.21}$$

B.3 Explicit Prescriptions

Here we give explicit expressions for all the umbral McKay-Thompson series H^X_g. Most of these appeared first in [15,16]. The expressions in §§B.3.3, B.3.4, B.3.7, B.3.14 are taken from [26]. The expressions in §§B.3.11, B.3.15, B.3.19, B.3.23 are taken from [14]. The expressions for H^X_g with $X = E_8^3$ appeared first in [25]. The expression for $H^{(6+3)}_{2B,1}$ in §B.3.6, and the expressions for $H^{(12+4)}_{4A,r}$ and $H^{(12+4)}_{8AB,r}$ in §B.3.13, appear here for the first time.

The labels for conjugacy classes in G^X are as in §A.2.

B.3.1 $\ell = 2$, $X = A_1^{24}$

We have $G^{(2)} = G^X \simeq M_{24}$ and $m^X = 2$. So for $g \in M_{24}$, the associated umbral McKay-Thompson series $H^{(2)}_g = (H^{(2)}_{g,r})$ is a 4-vector-valued function, with components indexed by $r \in \mathbb{Z}/4\mathbb{Z}$, satisfying $H^{(2)}_{g,r} = -H^{(2)}_{g,-r}$, and in particular, $H^{(2)}_{g,r} = 0$ for $r = 0 \mod 2$. So it suffices to specify the $H^{(2)}_{g,1}$ explicitly.

Define $H^{(2)}_g = (H^{(2)}_{g,r})$ for $g = e$ by requiring that

$$-2\Psi_{1,1}(\tau, z)\varphi^{(2)}_1(\tau, z) = -24\mu_{2,0}(\tau, z) + \sum_{r \mod 4} H^{(2)}_{e,r}(\tau)\theta_{2,r}(\tau, z), \tag{B.22}$$

where

$$\varphi^{(2)}_1(\tau, z) := 4\left(\frac{\theta_2(\tau, z)^2}{\theta_2(\tau, 0)^2} + \frac{\theta_3(\tau, z)^2}{\theta_3(\tau, 0)^2} + \frac{\theta_4(\tau, z)^2}{\theta_4(\tau, 0)^2}\right). \tag{B.23}$$

More generally, for $g \in G^{(2)}$ define

$$H^{(2)}_{g,1}(\tau) := \frac{\bar{\chi}^{(2)}_g}{24} H^{(2)}_{e,1}(\tau) - F^{(2)}_g(\tau)\frac{1}{S_{2,1}(\tau)}, \tag{B.24}$$

where $\bar{\chi}^{(2)}_g$ and $F^{(2)}_g$ are as specified in Table 36. Note that $\bar{\chi}^{(2)}_g = \bar{\chi}^{X_A}_g$, the latter appearing in Table 15. Also, $S_{2,1}(\tau) = \eta(\tau)^3$.

The functions $f_{23,a}$ and $f_{23,b}$ in Table 36 are cusp forms of weight two for $\Gamma_0(23)$, defined by

$$\begin{aligned} f_{23,a}(\tau) &:= \frac{\eta(\tau)^3\eta(23\tau)^3}{\eta(2\tau)\eta(46\tau)} + 3\eta(\tau)^2\eta(23\tau)^2 + 4\eta(\tau)\eta(2\tau)\eta(23\tau)\eta(46\tau) + 4\eta(2\tau)^2\eta(46\tau)^2, \\ f_{23,b}(\tau) &:= \eta(\tau)^2\eta(23\tau)^2. \end{aligned} \tag{B.25}$$

Note that the definition of $F^{(2)}_g$ appearing here for $g \in 23A \cup 23B$ corrects errors in [11,12].

Table 36: Character Values and Weight Two Forms for $\ell = 2$, $X = A_1^{24}$

$[g]$	$\bar{\chi}_g^{(2)}$	$F_g^{(2)}(\tau)$

$10A$	0	$2\eta(\tau)^3\eta(2\tau)\eta(5\tau)\eta(10\tau)^{-1}$
$11A$	2	$2(\Lambda_{11}(\tau)-11\eta(\tau)^2\eta(11\tau)^2)/5$
$12A$	0	$2\eta(\tau)^3\eta(4\tau)^2\eta(6\tau)^3\eta(2\tau)^{-1}\eta(3\tau)^{-1}\eta(12\tau)^{-2}$
$12B$	0	$2\eta(\tau)^4\eta(4\tau)\eta(6\tau)\eta(2\tau)^{-1}\eta(12\tau)^{-1}$
$14AB$	1	$(-\Lambda_2(\tau)-\Lambda_7(\tau)+\Lambda_{14}(\tau)-14\eta(\tau)\eta(2\tau)\eta(7\tau)\eta(14\tau))/3$
$15AB$	1	$(-\Lambda_3(\tau)-\Lambda_5(\tau)+\Lambda_{15}(\tau)-15\eta(\tau)\eta(3\tau)\eta(5\tau)\eta(15\tau))/4$
$21AB$	0	$(7\eta(\tau)^3\eta(7\tau)^3\eta(3\tau)^{-1}\eta(21\tau)^{-1}-\eta(\tau)^6\eta(3\tau)^{-2})/3$
$23AB$	1	$(\Lambda_{23}(\tau)-23f_{23,a}(\tau)-69f_{23,b}(\tau))/11$

B.3.2 $\ell = 3$, $X = A_2^{12}$

We have $G^{(3)} = G^X \simeq 2.M_{12}$ and $m^X = 3$. So for $g \in 2.M_{12}$, the associated umbral McKay-Thompson series $H_g^{(3)} = (H_{g,r}^{(3)})$ is a 6-vector-valued function, with components indexed by $r \in \mathbb{Z}/6\mathbb{Z}$, satisfying $H_{g,r}^{(3)} = -H_{g,-r}^{(3)}$, and in particular, $H_{g,r}^{(3)} = 0$ for $r = 0 \mod 3$. So it suffices to specify the $H_{g,1}^{(3)}$ and $H_{g,2}^{(3)}$ explicitly.

Define $H_g^{(3)} = (H_{g,r}^{(3)})$ for $g = e$ by requiring that

$$-2\Psi_{1,1}(\tau,z)\varphi_1^{(3)}(\tau,z) = -12\mu_{3,0}(\tau,z) + \sum_{r \mod 6} H_{e,r}^{(3)}(\tau)\theta_{3,r}(\tau,z), \tag{B.26}$$

where

$$\varphi_1^{(3)}(\tau,z) := 2\left(\frac{\theta_3(\tau,z)^2}{\theta_3(\tau,0)^2}\frac{\theta_4(\tau,z)^2}{\theta_4(\tau,0)^2} + \frac{\theta_4(\tau,z)^2}{\theta_4(\tau,0)^2}\frac{\theta_2(\tau,z)^2}{\theta_2(\tau,0)^2} + \frac{\theta_2(\tau,z)^2}{\theta_2(\tau,0)^2}\frac{\theta_3(\tau,z)^2}{\theta_3(\tau,0)^2}\right). \tag{B.27}$$

More generally, for $g \in G^{(3)}$ define

$$H^{(3)}_{g,1}(\tau) := \frac{\bar{\chi}^{(3)}_g}{12} H^{(3)}_{e,1}(\tau) + \frac{1}{2}\left(F^{(3)}_g + F^{(3)}_{zg}\right)\frac{1}{S_{3,1}(\tau)}, \tag{B.28}$$

$$H^{(3)}_{g,2}(\tau) := \frac{\chi^{(3)}_g}{12} H^{(3)}_{e,1}(\tau) + \frac{1}{2}\left(F^{(3)}_g - F^{(3)}_{zg}\right)\frac{1}{S_{3,2}(\tau)}, \tag{B.29}$$

where $\chi^{(3)}_g$ and $F^{(3)}_g$ are as specified in Table 37, and z is the non-trivial central element of $G^{(3)}$. The action of $g \mapsto zg$ on conjugacy classes can be read off Table 37, for the horizontal lines indicate the sets $[g] \cup [zg]$.

Note the eta product identities, $S_{3,1}(\tau) = \eta(2\tau)^5/\eta(4\tau)^2$, and $S_{3,2}(\tau) = 2\eta(\tau)^2\eta(4\tau)^2/\eta(2\tau)$. Note also that $\bar{\chi}^{(3)}_g = \bar{\chi}^{X_A}_g$ and $\chi^{(3)}_g = \chi^{X_A}_g$, the latter appearing in Table 16.

Table 37: Character Values and Weight Two Forms for $\ell = 3$, $X = A_2^{12}$

6C	1	1	$2(\Lambda_2(\tau) + \Lambda_3(\tau) - \Lambda_6(\tau))$
6D	1	-1	$-5\Lambda_2(\tau) - 2\Lambda_3(\tau) + \frac{5}{3}\Lambda_4(\tau) + 3\Lambda_6(\tau) - \Lambda_{12}(\tau)$
8AB	0	0	$-2\eta(2\tau)^4\eta(4\tau)^2/\eta(8\tau)^2$
8CD	2	0	$-2\Lambda_2(\tau) + \frac{5}{3}\Lambda_4(\tau) - \Lambda_8(\tau)$
20AB	0	0	$-2\eta(2\tau)^7\eta(5\tau)/\eta(\tau)\eta(4\tau)^2\eta(10\tau)$
11AB	1	1	$-\frac{2}{5}\Lambda_{11}(\tau) - \frac{33}{5}\eta(\tau)^2\eta(11\tau)^2$
22AB	1	-1	$\sum_{d\mid 44} c_g(d)\Lambda_d(\tau) - \frac{11}{5}\sum_{d\mid 4} c'_g(d)\eta(d\tau)^2\eta(11d\tau)^2 + \frac{22}{3}f_{44}(\tau)$

The function f_{44} is the unique new cusp form of weight 2 for $\Gamma_0(44)$, normalized so that $f_{44}(\tau) =$

$q+O(q^3)$ as $\Im(\tau)\to\infty$. The coefficients $c_g(d)$ and $c'_g(d)$ for $g\in 10A\cup 22A\cup 22B$ are given by

$$c_{10A}(2)=-5,\ c_{10A}(4)=-\frac{5}{3},\ c_{10A}(5)=-\frac{2}{3},\ c_{10A}(10)=1,\ c_{10A}(20)=-\frac{1}{3}, \tag{B.30}$$

$$c_{22AB}(2)=-\frac{11}{5},\ c_{22AB}(4)=\frac{11}{5},\ c_{22AB}(11)=-\frac{2}{15},\ c_{22AB}(22)=\frac{1}{5},\ c_{22AB}(44)=-\frac{1}{15}, \tag{B.31}$$

$$c'_{22AB}(1)=1,\ c'_{22AB}(2)=4,\ c'_{22AB}(4)=8. \tag{B.32}$$

B.3.3 $\ell=4$, $X=A_3^8$

We have $m^X=4$, so the umbral McKay-Thompson series $H_g^{(4)}=(H_{g,r}^{(4)})$ associated to $g\in G^{(4)}$ is an 8-vector-valued function, with components indexed by $r\in\mathbb{Z}/8\mathbb{Z}$.

Define $H_g^{(4)}=(H_{g,r}^{(4)})$ for $g\in G^{(4)}$, $g\notin 4C$, by requiring that

$$\psi_g^{(4)}(\tau,z)=-\chi_g^{(4)}\mu_{4,0}^0(\tau,z)-\bar{\chi}_g^{(4)}\mu_{4,0}^1(\tau,z)+\sum_{r \bmod 8}H_{g,r}^{(4)}(\tau)\theta_{4,r}(\tau,z), \tag{B.33}$$

where $\chi_g^{(4)}:=\chi_g^{X_A}$ and $\bar{\chi}_g^{(4)}:=\bar{\chi}_g^{X_A}$ (cf. Table 17), and the $\psi_g^{(4)}$ are meromorphic Jacobi forms of weight 1 and index 4 given explicitly in Table 38.

Table 38: Character Values and Meromorphic Jacobi Forms for $\ell=4$, $X=A_3^8$

$[g]$	$\chi_g^{(4)}$	$\bar{\chi}_g^{(4)}$	$\psi_g^{(4)}(\tau,z)$
1A	8	8	$2i\theta_1(\tau,2z)^3\theta_1(\tau,z)^{-4}\eta(\tau)^3$
2A	-8	8	$2i\theta_1(\tau,2z)^3\theta_2(\tau,z)^{-4}\eta(\tau)^3$
2B	0	0	$-2i\theta_1(\tau,2z)^3\theta_1(\tau,z)^{-2}\theta_2(\tau,z)^{-2}\eta(\tau)^3$

4C	0	2	$2i\theta_1(\tau,2z)\theta_2(2\tau,4z)\theta_1(2\tau,2z)^{-2}\eta(2\tau)^7\eta(\tau)^{-3}\eta(4\tau)^{-2}$
7AB	1	1	cf. (B.34)
14AB	-1	1	cf. (B.34)

$$\begin{aligned}
\psi^{(4)}_{6BC} &:= \left(\theta_1(\tau, z+\tfrac{1}{3})\theta_1(\tau, z+\tfrac{1}{6}) - \theta_1(\tau, z-\tfrac{1}{3})\theta_1(\tau, z-\tfrac{1}{6})\right) \frac{-i\theta_1(3\tau, 6z)}{\theta_1(3\tau, 3z)\theta_2(3\tau, 3z)}\eta(3\tau) \\
\psi^{(4)}_{7AB} &:= \left(\prod_{j=1}^{3}\theta_1(\tau, 2z+\tfrac{j^2}{7})\theta_1(\tau, z-\tfrac{j^2}{7}) + \prod_{j=1}^{3}\theta_1(\tau, 2z-\tfrac{j^2}{7})\theta_1(\tau, z+\tfrac{j^2}{7})\right) \frac{-i}{\theta_1(7\tau, 7z)}\frac{\eta(7\tau)}{\eta(\tau)^4} \\
\psi^{(4)}_{14AB} &:= \left(\prod_{j=1}^{3}\theta_1(\tau, 2z+\tfrac{j^2}{7})\theta_2(\tau, z-\tfrac{j^2}{7}) + \prod_{j=1}^{3}\theta_1(\tau, 2z-\tfrac{j^2}{7})\theta_2(\tau, z+\tfrac{j^2}{7})\right) \frac{i}{\theta_2(7\tau, 7z)}\frac{\eta(7\tau)}{\eta(\tau)^4}
\end{aligned} \tag{B.34}$$

For use later on, note that $\psi^{(4)}_{1A} = -2\Psi_{1,1}\varphi^{(4)}_1$, where

$$\varphi^{(4)}_1(\tau, z) := \frac{\theta_1(\tau, 2z)^2}{\theta_1(\tau, z)^2}. \tag{B.35}$$

B.3.4 $\ell = 5$, $X = A_4^6$

We have $m^X = 5$, so the umbral McKay-Thompson series $H^{(5)}_g = (H^{(5)}_{g,r})$ associated to $g \in G^{(5)}$ is a 10-vector-valued function, with components indexed by $r \in \mathbb{Z}/10\mathbb{Z}$.

Define $H^{(5)}_g = (H^{(5)}_{g,r})$ for $g \in G^{(5)}$, $g \notin 5A \cup 10A$, by requiring that

$$\psi^{(5)}_g(\tau, z) = -\chi^{(5)}_g \mu^0_{5,0}(\tau, z) - \bar{\chi}^{(5)}_g \mu^1_{5,0}(\tau, z) + \sum_{r \bmod 10} H^{(5)}_{g,r}(\tau)\theta_{5,r}(\tau, z), \tag{B.36}$$

where $\chi^{(5)}_g := \chi^{X_A}_g$ and $\bar{\chi}^{(5)}_g := \bar{\chi}^{X_A}_g$ (cf. Table 18), and the $\psi^{(5)}_g$ are meromorphic Jacobi forms of weight 1 and index 5 given explicitly in Table 39.

Table 39: Character Values and Meromorphic Jacobi Forms for $\ell = 5$, $X = A_4^6$

$[g]$	$\chi^{(5)}_g$	$\bar{\chi}^{(5)}_g$	$\psi^{(5)}_g(\tau, z)$
1A	6	6	$2i\theta_1(\tau, 2z)\theta_1(\tau, 3z)\theta_1(\tau, z)^{-3}\eta(\tau)^3$
2A	-6	6	$-2i\theta_1(\tau, 2z)\theta_2(\tau, 3z)\theta_2(\tau, z)^{-3}\eta(\tau)^3$
2B	-2	2	$-2i\theta_1(\tau, 2z)\theta_1(\tau, 3z)\theta_1(\tau, z)^{-1}\theta_2(\tau, z)^{-2}\eta(\tau)^3$

3A	0	0	$-2i\theta_1(\tau, 2z)\theta_1(\tau, 3z)\theta_1(3\tau, 3z)^{-1}\eta(3\tau)$
6A	0	0	$-2i\theta_1(\tau, 2z)\theta_2(\tau, 3z)\theta_2(3\tau, 3z)^{-1}\eta(3\tau)$
4AB	0	0	cf. (B.37)
4CD	0	2	cf. (B.37)
12AB	0	0	cf. (B.37)

$$\begin{aligned}\psi^{(5)}_{4AB}(\tau,z)&:=-i\theta_2(\tau,2z)\frac{\theta_1(\tau,z+\frac14)\theta_1(\tau,3z+\frac14)-\theta_1(\tau,z-\frac14)\theta_1(\tau,3z-\frac14)}{\theta_2(2\tau,2z)^2}\frac{\eta(2\tau)^2}{\eta(\tau)}\\ \psi^{(5)}_{4CD}(\tau,z)&:=-i\theta_2(\tau,2z)\frac{\theta_1(\tau,z+\frac14)\theta_1(\tau,3z-\frac14)+\theta_1(\tau,z-\frac14)\theta_1(\tau,3z+\frac14)}{\theta_1(2\tau,2z)\theta_2(2\tau,2z)}\frac{\eta(2\tau)^2}{\eta(\tau)}\\ \psi^{(5)}_{12AB}(\tau,z)&:=i\frac{\theta_2(\tau,2z)}{\theta_2(6\tau,6z)}\left(\theta_1(\tau,z+\tfrac{1}{12})\theta_1(\tau,z+\tfrac14)\theta_1(\tau,z+\tfrac{5}{12})\theta_1(\tau,3z-\tfrac14)\right.\\ &\qquad\left.-\theta_1(\tau,z-\tfrac{1}{12})\theta_1(\tau,z-\tfrac14)\theta_1(\tau,z-\tfrac{5}{12})\theta_1(\tau,3z+\tfrac14)\right)\frac{\eta(6\tau)}{\eta(\tau)^3}\end{aligned}\tag{B.37}$$

For $g\in 5A$ use the formulas of §B.3.20 to define

$$H^{(5)}_{5A,r}(\tau):=H^{(25)}_{1A,r}(\tau/5)-H^{(25)}_{1A,10-r}(\tau/5)+H^{(25)}_{1A,10+r}(\tau/5)-H^{(25)}_{1A,20-r}(\tau/5)+H^{(25)}_{1A,20+r}(\tau/5).\tag{B.38}$$

For $g\in 10A$ set $H^{(5)}_{10A,r}(\tau):=-(-1)^rH^{(5)}_{5A,r}(\tau)$.

For use later on we note that $\psi^{(5)}_{1A}=-2\Psi_{1,1}\varphi^{(5)}_1$, where

$$\varphi^{(5)}_1(\tau,z):=\frac{\theta_1(\tau,3z)}{\theta_1(\tau,z)}.\tag{B.39}$$

B.3.5 $\ell=6$, $X=A_5^4D_4$

We have $m^X=6$, so the umbral McKay-Thompson series $H^{(6)}_g=(H^{(6)}_{g,r})$ associated to $g\in G^{(6)}$ is a 12-vector-valued function with components indexed by $r\in\mathbb{Z}/12\mathbb{Z}$. We have $H^{(6)}_{g,r}=-H^{(6)}_{g,-r}$, so it suffices to specify the $H^{(6)}_{g,r}$ for $r\in\{1,2,3,4,5\}$.

To define $H^{(6)}_g=(H^{(6)}_{g,r})$ for $g=e$, first define $h(\tau)=(h_r(\tau))$ by requiring that

$$-2\Psi_{1,1}(\tau,z)\varphi^{(6)}_1(\tau,z)=-24\mu_{6,0}(\tau,z)+\sum_{r\bmod 12}h_r(\tau)\theta_{6,r}(\tau,z),\tag{B.40}$$

where

$$\varphi^{(6)}_1(\tau,z):=\varphi^{(2)}_1(\tau,z)\varphi^{(5)}_1(\tau,z)-\varphi^{(3)}_1(\tau,z)\varphi^{(4)}_1(\tau,z).\tag{B.41}$$

(Cf. (B.23), (B.27), (B.35), (B.39).) Now define the $H^{(6)}_{1A,r}$ by setting

$$\begin{aligned}H^{(6)}_{1A,1}(\tau)&:=\frac{1}{24}\left(5h_1(\tau)+h_5(\tau)\right),\\ H^{(6)}_{1A,2}(\tau)&:=\frac16h_2(\tau),\\ H^{(6)}_{1A,3}(\tau)&:=\frac14h_3(\tau),\\ H^{(6)}_{1A,4}(\tau)&:=\frac16h_4(\tau),\\ H^{(6)}_{1A,5}(\tau)&:=\frac{1}{24}\left(h_1(\tau)+5h_5(\tau)\right).\end{aligned}\tag{B.42}$$

Define $H^{(6)}_{2A,r}$ by requiring

$$H^{(6)}_{2A,r}(\tau) := -(-1)^r H^{(6)}_{1A,r}(\tau). \tag{B.43}$$

For the remaining g, recall (B.13). The $H^{(6)}_{g,r}$ for $g \notin 1A \cup 2A$ are defined as follows for $r = 2$ and $r = 4$, noting that $H^{(3)}_{g,4} = H^{(3)}_{g,-2} = -H^{(3)}_{g,2}$.

$$\begin{aligned}
H^{(6)}_{2B,r}(\tau) &:= [-\tfrac{r^2}{24}]H^{(3)}_{4C,r}(\tau/2)\\
H^{(6)}_{4A,r}(\tau) &:= [-\tfrac{r^2}{24}]H^{(3)}_{4B,r}(\tau/2)\\
H^{(6)}_{3A,r}(\tau) &:= [-\tfrac{r^2}{24}]H^{(3)}_{6C,r}(\tau/2)\\
H^{(6)}_{6A,r}(\tau) &:= [-\tfrac{r^2}{24}]H^{(3)}_{6D,r}(\tau/2)\\
H^{(6)}_{8AB,r}(\tau) &:= [-\tfrac{r^2}{24}]H^{(3)}_{8CD,r}(\tau/2)
\end{aligned} \tag{B.44}$$

For the $H^{(6)}_{g,3}$ we define

$$\begin{aligned}
H^{(6)}_{2B,3}(\tau), H^{(6)}_{4A,3}(\tau) &:= -[-\tfrac{9}{24}]H^{(2)}_{6A,1}(\tau/3),\\
H^{(6)}_{3A,3}(\tau), H^{(6)}_{6A,3}(\tau) &:= 0,\\
H^{(6)}_{8AB,3}(\tau) &:= -[-\tfrac{9}{24}]H^{(2)}_{12A,1}(\tau/3).
\end{aligned} \tag{B.45}$$

Noting that $H^{(2)}_{g,5} = H^{(2)}_{g,1}$ and $H^{(3)}_{g,5} = -H^{(3)}_{g,1}$, the $H^{(6)}_{g,1}$ and $H^{(6)}_{g,5}$ are defined for $o(g) \neq 0 \mod 3$ by setting

$$\begin{aligned}
H^{(6)}_{2B,r}(\tau) &:= [-\tfrac{1}{24}]\frac{1}{2}\left(H^{(2)}_{6A,r}(\tau/3) + H^{(3)}_{4C,r}(\tau/2)\right)\\
H^{(6)}_{4A,r}(\tau) &:= [-\tfrac{1}{24}]\frac{1}{2}\left(H^{(2)}_{6A,r}(\tau/3) + H^{(3)}_{4B,r}(\tau/2)\right)\\
H^{(6)}_{8AB,r}(\tau) &:= [-\tfrac{1}{24}]\frac{1}{2}\left(H^{(2)}_{12A,r}(\tau/3) + H^{(3)}_{8CD,r}(\tau/2)\right)
\end{aligned} \tag{B.46}$$

It remains to specify the $H^{(6)}_{g,r}$ when $g \in 3A \cup 6A$ and r is 1 or 5. These cases are determined by using the formulas of §B.3.17 to set

$$\begin{aligned}
H^{(6)}_{3A,1}(\tau), H^{(6)}_{6A,1}(\tau) &:= H^{(18)}_{1A,1}(3\tau) - H^{(18)}_{1A,11}(3\tau) + H^{(18)}_{1A,13}(3\tau),\\
H^{(6)}_{3A,5}(\tau), H^{(6)}_{6A,5}(\tau) &:= H^{(18)}_{1A,5}(3\tau) - H^{(18)}_{1A,7}(3\tau) + H^{(18)}_{1A,17}(3\tau).
\end{aligned} \tag{B.47}$$

B.3.6 $\ell = 6+3$, $X = D_4^6$

We have $m^X = 6$, so the umbral McKay-Thompson series $H^{(6+3)}_g = (H^{(6+3)}_{g,r})$ associated to $g \in G^{(6+3)}$ is a 12-vector-valued function with components indexed by $r \in \mathbb{Z}/12\mathbb{Z}$. In addition to the identity $H^{(6+3)}_{g,r} = -H^{(6+3)}_{g,-r}$, we have $H^{(6+3)}_{g,r} = 0$ for $r = 0 \mod 2$. Thus it suffices to specify the $H^{(6+3)}_{g,r}$ for $r \in \{1, 3, 5\}$.

Recall (B.13). For $r=1$, define

$$\begin{aligned}
H^{(6+3)}_{1A,1}(\tau), H^{(6+3)}_{3A,1}(\tau) &:= H^{(6)}_{1A,1}(\tau) + H^{(6)}_{1A,5}(\tau),\\
H^{(6+3)}_{2A,1}(\tau), H^{(6+3)}_{6A,1}(\tau) &:= H^{(6)}_{2B,1}(\tau) + H^{(6)}_{2B,5}(\tau),\\
H^{(6+3)}_{3B,1}(\tau) &:= H^{(6)}_{3A,1}(\tau) + H^{(6)}_{3A,5}(\tau),\\
H^{(6+3)}_{3C,1}(\tau) &:= -2\frac{\eta(\tau)^2}{\eta(3\tau)},\\
H^{(6+3)}_{4A,1}(\tau), H^{(6+3)}_{12A,1}(\tau) &:= H^{(6)}_{8AB,1}(\tau) + H^{(6)}_{8AB,5}(\tau),\\
H^{(6+3)}_{5A,1}(\tau), H^{(6+3)}_{15A,1}(\tau) &:= [-\tfrac{1}{24}]H^{(2)}_{15AB,1}(\tau/3),\\
H^{(6+3)}_{2C,1}(\tau) &:= H^{(6)}_{4A,1}(\tau) - H^{(6)}_{4A,5}(\tau),\\
H^{(6+3)}_{4B,1}(\tau) &:= H^{(6)}_{8AB,1}(\tau) - H^{(6)}_{8AB,5}(\tau),\\
H^{(6+3)}_{6B,1}(\tau) &:= H^{(6)}_{6A,1}(\tau) - H^{(6)}_{6A,5}(\tau),\\
H^{(6+3)}_{6C,1}(\tau) &:= -2\frac{\eta(2\tau)\,\eta(3\tau)}{\eta(6\tau)}.
\end{aligned} \tag{B.48}$$

Then define $H^{(6+3)}_{2B,1}$ by setting

$$H^{(6+3)}_{2B,1}(\tau) := 2H^{(6+3)}_{4B,1}(\tau) + 2\frac{\eta(\tau)^3}{\eta(2\tau)^2}. \tag{B.49}$$

For $r=3$ set

$$\begin{aligned}
H^{(6+3)}_{1A,3}(\tau) &:= 2H^{(6)}_{1A,3}(\tau),\\
H^{(6+3)}_{3A,3}(\tau) &:= -H^{(6)}_{1A,3}(\tau),\\
H^{(6+3)}_{2A,3}(\tau) &:= 2H^{(6)}_{2B,3}(\tau),\\
H^{(6+3)}_{6A,3}(\tau) &:= -H^{(6)}_{2B,3}(\tau),\\
H^{(6+3)}_{4A,3}(\tau) &:= 2H^{(6)}_{8AB,3}(\tau),\\
H^{(6+3)}_{12A,3}(\tau) &:= -H^{(6)}_{8AB,3}(\tau),\\
H^{(6+3)}_{5A,3}(\tau) &:= -2[-\tfrac{9}{24}]H^{(2)}_{15AB,1}(\tau),\\
H^{(6+3)}_{15A,3}(\tau) &:= [-\tfrac{9}{24}]H^{(2)}_{15AB,1}(\tau),
\end{aligned} \tag{B.50}$$

and

$$H^{(6+3)}_{3B,3}(\tau), H^{(6+3)}_{3C,3}(\tau), H^{(6+3)}_{2B,3}(\tau), H^{(6+3)}_{2C,3}(\tau), H^{(6+3)}_{4B,3}(\tau), H^{(6+3)}_{6B,3}(\tau), H^{(6+3)}_{6C,3}(\tau) := 0. \tag{B.51}$$

For $r=5$ define $H^{(6+3)}_{g,5}(\tau) := H^{(6+3)}_{g,1}(\tau)$ for $[g] \in \{1A, 3A, 2A, 6A, 3B, 3C, 4A, 12A, 5A, 15AB\}$, and set $H^{(6+3)}_{g,5}(\tau) := -H^{(6+3)}_{g,1}(\tau)$ for the remaining cases, $[g] \in \{2B, 2C, 4B, 6B, 6C\}$.

B.3.7 $\ell = 7$, $X = A_6^4$

We have $m^X = 7$, so the umbral McKay-Thompson series $H_g^{(7)} = (H_{g,r}^{(7)})$ associated to $g \in G^{(7)} = G^X \simeq SL_2(3)$ is a 14-vector-valued function, with components indexed by $r \in \mathbb{Z}/14\mathbb{Z}$.

Define $H_g^{(7)} = (H_{g,r}^{(7)})$ for $g \in G^{(7)}$ by requiring that

$$\psi_g^{(7)}(\tau, z) = -\chi_g^{(7)}\mu_{7,0}^0(\tau, z) - \bar{\chi}_g^{(7)}\mu_{7,0}^1(\tau, z) + \sum_{r \bmod 14} H_{g,r}^{(7)}(\tau)\theta_{7,r}(\tau, z), \tag{B.52}$$

where $\chi_g^{(7)} := \chi_g^{X_A}$ and $\bar{\chi}_g^{(7)} := \bar{\chi}_g^{X_A}$ (cf. Table 21), and the $\psi_g^{(7)}$ are meromorphic Jacobi forms of weight 1 and index 7 given explicitly in Table 40.

Table 40: Character Values and Meromorphic Jacobi Forms for $\ell = 7$, $X = A_6^4$

$[g]$	$\chi_g^{(7)}$	$\bar{\chi}_g^{(7)}$	$\psi_g^{(7)}(\tau, z)$
1A	4	4	$2i\theta_1(\tau, 4z)\theta_1(\tau, z)^{-2}\eta(\tau)^3$
2A	-4	4	$-2i\theta_1(\tau, 4z)\theta_2(\tau, z)^{-2}\eta(\tau)^3$
4A	0	0	$-2i\theta_1(\tau, 4z)\theta_2(2\tau, 2z)^{-1}\eta(2\tau)\eta(\tau)$
3A	1	1	cf. (B.53)
6A	-1	1	cf. (B.53)

$$\begin{aligned}
\psi_{3A}^{(7)}(\tau, z) &:= -i\frac{\theta_1(\tau, 4z + \frac{1}{3})\theta_1(\tau, z - \frac{1}{3}) + \theta_1(\tau, 4z - \frac{1}{3})\theta_1(\tau, z + \frac{1}{3})}{\theta_1(3\tau, 3z)}\eta(3\tau) \\
\psi_{6A}^{(7)}(\tau, z) &:= -i\frac{\theta_1(\tau, 4z + \frac{1}{3})\theta_1(\tau, z - \frac{1}{6}) - \theta_1(\tau, 4z - \frac{1}{3})\theta_1(\tau, z + \frac{1}{6})}{\theta_2(3\tau, 3z)}\eta(3\tau)
\end{aligned} \tag{B.53}$$

For use later on we note that $\psi_{1A}^{(7)} = -2\Psi_{1,1}\varphi_1^{(7)}$, where

$$\varphi_1^{(7)}(\tau, z) := \frac{\theta_1(\tau, 4z)}{\theta_1(\tau, 2z)}. \tag{B.54}$$

B.3.8 $\ell = 8$, $X = A_7^2 D_5^2$

We have $m^X = 8$, so the umbral McKay-Thompson series $H_g^{(8)} = (H_{g,r}^{(8)})$ associated to $g \in G^{(8)}$ is a 16-vector-valued function with components indexed by $r \in \mathbb{Z}/16\mathbb{Z}$. We have $H_{g,r}^{(8)} = -H_{g,-r}^{(8)}$, so it suffices to specify the $H_{g,r}^{(8)}$ for $r \in \{1, 2, 3, 4, 5, 6, 7\}$.

To define $H_g^{(8)} = (H_{g,r}^{(8)})$ for $g = e$, first define $h(\tau) = (h_r(\tau))$ by requiring that

$$-2\Psi_{1,1}(\tau, z)\left(\varphi_1^{(8)}(\tau, z) + \frac{1}{2}\varphi_2^{(8)}(\tau, z)\right) = -24\mu_{8,0}(\tau, z) + \sum_{r \bmod 16} h_r(\tau)\theta_{8,r}(\tau, z), \tag{B.55}$$

where

$$\begin{aligned}
\varphi_1^{(8)}(\tau, z) &:= \varphi_1^{(3)}(\tau, z)\varphi_1^{(6)}(\tau, z) - 5\varphi_1^{(4)}(\tau, z)\varphi_1^{(5)}(\tau, z), \\
\varphi_2^{(8)}(\tau, z) &:= \varphi_1^{(4)}(\tau, z)\varphi_1^{(5)}(\tau, z) - \varphi_1^{(8)}(\tau, z).
\end{aligned} \tag{B.56}$$

(Cf. (B.27), (B.35), (B.39), (B.41).) Now define the $H^{(8)}_{1A,r}$ by setting

$$H^{(8)}_{1A,r}(\tau) := \frac{1}{6}h_r(\tau), \tag{B.57}$$

for $r \in \{1,3,4,5,7\}$, and

$$H^{(8)}_{1A,2}(\tau), H^{(8)}_{1A,6}(\tau) := \frac{1}{12}\left(h_2(\tau) + h_6(\tau)\right). \tag{B.58}$$

Define $H^{(8)}_{2A,r}$ for $1 \leq r \leq 7$ by requiring

$$H^{(8)}_{2A,r}(\tau) := -(-1)^r H^{(8)}_{1A,r}(\tau). \tag{B.59}$$

For the remaining g, recall (B.13). The $H^{(8)}_{g,r}$ for $g \in 2B \cup 2C \cup 4A$ are defined as follows for $r \in \{1,3,5,7\}$, noting that $H^{(4)}_{g,7} = H^{(4)}_{g,-1} = -H^{(4)}_{g,1}$, &c.

$$\begin{aligned} H^{(8)}_{2BC,r}(\tau) &:= [-\tfrac{r^2}{32}]H^{(4)}_{4C,r}(\tau/2) \\ H^{(8)}_{4A,r}(\tau) &:= [-\tfrac{r^2}{32}]H^{(4)}_{4B,r}(\tau/2) \end{aligned} \tag{B.60}$$

The $H^{(8)}_{2BC,r}$ and $H^{(8)}_{4A,r}$ vanish for $r = 0 \mod 2$.

B.3.9 $\ell = 9$, $X = A_8^3$

We have $m^X = 9$, so for $g \in G^{(9)}$ the associated umbral McKay-Thompson series $H^{(9)}_g = (H^{(9)}_{g,r})$ is a 18-vector-valued function, with components indexed by $r \in \mathbb{Z}/18\mathbb{Z}$, satisfying $H^{(9)}_{g,r} = -H^{(9)}_{g,-r}$, and in particular, $H^{(9)}_{g,r} = 0$ for $r = 0 \mod 9$. So it suffices to specify the $H^{(9)}_{g,r}$ for $r \in \{1,2,3,4,5,6,7,8\}$.

Define $H^{(9)}_g = (H^{(9)}_{g,r})$ for $g = e$ by requiring that

$$-\Psi_{1,1}(\tau,z)\varphi^{(9)}_1(\tau,z) = -3\mu_{9,0}(\tau,z) + \sum_{r \mod 18} H^{(9)}_{e,r}(\tau)\theta_{9,r}(\tau,z), \tag{B.61}$$

where

$$\varphi^{(9)}_1(\tau,z) := \varphi^{(3)}_1(\tau,z)\varphi^{(7)}_1(\tau,z) - \varphi^{(5)}_1(\tau,z)^2. \tag{B.62}$$

(Cf. (B.27), (B.39), (B.54).)

Recall (B.13). The $H^{(9)}_{2B,r}$ are defined for $r \in \{1,2,4,5,7,8\}$ by setting

$$H^{(9)}_{2B,r}(\tau) := [-\tfrac{r^2}{36}]H^{(3)}_{6C,r}(\tau/3), \tag{B.63}$$

where we note that $H^{(3)}_{g,4} = H^{(3)}_{g,-2} = -H^{(3)}_{g,2}$, &c. We determine $H^{(9)}_{2B,3}$ and $H^{(9)}_{2B,6}$ by using §B.3.17 to set

$$H^{(9)}_{2B,r}(\tau) := H^{(18)}_{1A,r}(2\tau) - H^{(18)}_{1A,18-r}(2\tau) \tag{B.64}$$

for $r \in \{3,6\}$.

The $H^{(9)}_{3A,r}$ are defined by the explicit formulas

$$\begin{aligned}
H^{(9)}_{3A,1}(\tau) &:= [-\tfrac{1}{36}]f^{(9)}_1(\tau/3),\\
H^{(9)}_{3A,2}(\tau) &:= [-\tfrac{4}{36}]f^{(9)}_2(\tau/3),\\
H^{(9)}_{3A,3}(\tau) &:= -\theta_{3,3}(\tau,0),\\
H^{(9)}_{3A,4}(\tau) &:= -[-\tfrac{16}{36}]f^{(9)}_2(\tau/3),\\
H^{(9)}_{3A,5}(\tau) &:= -[-\tfrac{25}{36}]f^{(9)}_1(\tau/3),\\
H^{(9)}_{3A,6}(\tau) &:= \theta_{3,0}(\tau,0),\\
H^{(9)}_{3A,7}(\tau) &:= [-\tfrac{13}{36}]f^{(9)}_1(\tau/3),\\
H^{(9)}_{3A,8}(\tau) &:= [-\tfrac{28}{36}]f^{(9)}_2(\tau/3),
\end{aligned} \tag{B.65}$$

where

$$\begin{aligned}
f^{(9)}_1(\tau) &:= -2\frac{\eta(\tau)\eta(12\tau)\eta(18\tau)^2}{\eta(6\tau)\eta(9\tau)\eta(36\tau)},\\
f^{(9)}_2(\tau) &:= \frac{\eta(2\tau)^6\eta(12\tau)\eta(18\tau)^2}{\eta(\tau)\eta(4\tau)^4\eta(6\tau)\eta(9\tau)\eta(36\tau)} - \frac{\eta(\tau)\eta(2\tau)\eta(3\tau)^2}{\eta(4\tau)^2\eta(9\tau)}.
\end{aligned} \tag{B.66}$$

Finally, the $H^{(9)}_{g,r}$ are determined for $g \in 2A \cup 2C \cup 6A$ by setting

$$\begin{aligned}
H^{(9)}_{2A,r}(\tau) &:= (-1)^{r+1}H^{(9)}_{1A,r}(\tau),\\
H^{(9)}_{2C,r}(\tau) &:= (-1)^{r+1}H^{(9)}_{2B,r}(\tau),\\
H^{(9)}_{6A,r}(\tau) &:= (-1)^{r+1}H^{(9)}_{3A,r}(\tau).
\end{aligned} \tag{B.67}$$

B.3.10 $\ell = 10$, $X = A_9^2D_6$

We have $m^X = 10$, so the umbral McKay-Thompson series $H^{(10)}_g = (H^{(10)}_{g,r})$ associated to $g \in G^{(10)}$ is a 20-vector-valued function with components indexed by $r \in \mathbb{Z}/20\mathbb{Z}$. We have $H^{(10)}_{g,r} = -H^{(10)}_{g,-r}$, so it suffices to specify the $H^{(10)}_{g,r}$ for $1 \leq r \leq 9$.

To define $H^{(10)}_g = (H^{(10)}_{g,r})$ for $g = e$, first define $h(\tau) = (h_r(\tau))$ by requiring that

$$-6\Psi_{1,1}(\tau,z)\varphi^{(10)}_1(\tau,z) = -24\mu_{10,0}(\tau,z) + \sum_{r \mod 20} h_r(\tau)\theta_{10,r}(\tau,z), \tag{B.68}$$

where

$$\varphi^{(10)}_1(\tau,z) := 5\varphi^{(4)}_1(\tau,z)\varphi^{(7)}_1(\tau,z) - \varphi^{(5)}_1(\tau,z)\varphi^{(6)}_1(\tau,z). \tag{B.69}$$

(Cf. (B.35), (B.39), (B.41), (B.54).) Now define the $H^{(10)}_{1A,r}$ for r odd by setting

$$\begin{aligned} H^{(10)}_{1A,1}(\tau) &:= \frac{1}{24}\left(3h_1(\tau)+h_9(\tau)\right),\\ H^{(10)}_{1A,3}(\tau) &:= \frac{1}{24}\left(3h_3(\tau)+h_7(\tau)\right),\\ H^{(10)}_{1A,5}(\tau) &:= \frac{1}{6}h_5(\tau),\\ H^{(10)}_{1A,3}(\tau) &:= \frac{1}{24}\left(h_3(\tau)+3h_7(\tau)\right),\\ H^{(10)}_{1A,9}(\tau) &:= \frac{1}{24}\left(h_1(\tau)+3h_9(\tau)\right). \end{aligned} \tag{B.70}$$

For $r = 0 \mod 2$ set

$$H^{(10)}_{1A,r}(\tau) := \frac{1}{12}h_r(\tau), \tag{B.71}$$

and define $H^{(10)}_{2A,r}$ for $1 \leq r \leq 9$ by requiring

$$H^{(10)}_{2A,r}(\tau) := -(-1)^r H^{(10)}_{1A,r}(\tau). \tag{B.72}$$

It remains to specify $H^{(10)}_{g,r}$ for $g \in 4A \cup 4B$. For $r = 0 \mod 2$ set

$$H^{(10)}_{4AB,r}(\tau) := 0. \tag{B.73}$$

For r odd, recall (B.13), and define

$$H^{(10)}_{4A,r}(\tau) := [-\tfrac{r^2}{40}]\frac{1}{2}\left(H^{(2)}_{10A,r}(\tau/5) + H^{(5)}_{4CD,r}(\tau/2)\right). \tag{B.74}$$

B.3.11 $\ell = 10+5$, $X = D_6^4$

We have $m^X = 10$, so the umbral McKay-Thompson series $H^{(10+5)}_g = (H^{(10+5)}_{g,r})$ associated to $g \in G^{(10+5)}$ is a 20-vector-valued function with components indexed by $r \in \mathbb{Z}/20\mathbb{Z}$. We have $H^{(10+5)}_{g,r} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H^{(10+5)}_{g,r}$ for r odd. Observing that $H^{(10+5)}_{g,r} = -H^{(10+5)}_{g,-r}$ we may determine $H^{(10+5)}_g$ by requiring that

$$\psi^{(5/2)}_g(\tau,z) = -2\chi^{(5/2)}_g i\mu_{5/2,0}(\tau,z) + \sum_{\substack{r\in\mathbb{Z}+1/2\\ r \mod 5}} e(-r/2)H^{(10+5)}_{g,2r}(\tau)\theta_{5/2,r}(\tau,z), \tag{B.75}$$

where $\chi^{(5/2)}_g := \bar{\chi}^{X_D}_g$ as in Table 25, and the $\psi^{(5/2)}_g$ are the meromorphic Jacobi forms of weight 1 and index 5/2 defined as follows.

Table 41: Character Values and Meromorphic Jacobi Forms for $\ell = 10 + 5$, $X = D_6^4$

$[g]$	$\bar{\chi}_g^{(5/2)}$	$\psi_g^{(5/2)}(\tau, z)$
1A	4	$2i\theta_1(\tau, 2z)^2\theta_1(\tau, z)^{-3}\eta(\tau)^3$
2A	0	$-2i\theta_1(\tau, 2z)^2\theta_1(\tau, z)^{-1}\theta_2(\tau, z)^{-2}\eta(\tau)^3$
3A	1	$2i\theta_1(3\tau, 6z)\theta_1(\tau, 2z)^{-1}\theta_1(3\tau, 3z)^{-1}\eta(\tau)^3$
2B	2	$2i\theta_1(\tau, 2z)\theta_2(\tau, 2z)\theta_1(\tau, z)^{-2}\theta_2(\tau, z)^{-1}\eta(\tau)^3$
4A	0	$-2i\theta_1(\tau, 2z)\theta_2(\tau, 2z)\theta_2(2\tau, 2z)^{-1}\eta(\tau)\eta(2\tau)$

B.3.12 $\ell = 12$, $X = A_{11}D_7E_6$

We have $m^X = 12$, so the umbral McKay-Thompson series $H_g^{(12)} = (H_{g,r}^{(12)})$ associated to $g \in G^{(12)} \simeq \mathbb{Z}/2\mathbb{Z}$ is a 24-vector-valued function with components indexed by $r \in \mathbb{Z}/24\mathbb{Z}$. We have $H_{g,r}^{(12)} = -H_{g,-r}^{(12)}$, so it suffices to specify the $H_{g,r}^{(12)}$ for $1 \leq r \leq 11$.

To define $H_e^{(12)} = (H_{e,r}^{(12)})$, first define $h(\tau) = (h_r(\tau))$ by requiring that

$$-2\Psi_{1,1}(\tau, z)\left(\varphi_1^{(12)}(\tau, z) + \varphi_2^{(12)}(\tau, z)\right) = -24\mu_{12,0}(\tau, z) + \sum_{r \bmod 24} h_r(\tau)\theta_{12,r}(\tau, z), \tag{B.76}$$

where

$$\begin{aligned}\varphi_1^{(12)}(\tau, z) &:= 3\varphi_1^{(3)}(\tau, z)\varphi_1^{(10)}(\tau, z) - 8\varphi_1^{(4)}(\tau, z)\varphi_1^{(9)}(\tau, z) + \varphi_1^{(5)}(\tau, z)\varphi_1^{(8)}(\tau, z),\\ \varphi_2^{(12)}(\tau, z) &:= 4\varphi_1^{(4)}(\tau, z)\varphi_1^{(9)}(\tau, z) - \varphi_1^{(5)}(\tau, z)\varphi_1^{(8)}(\tau, z) - \varphi_1^{(12)}(\tau, z).\end{aligned} \tag{B.77}$$

(Cf. (B.27), (B.35), (B.39), (B.54), (B.56), (B.62), (B.69).) Now define the $H_{1A,r}^{(12)}$ for $r \neq 0 \mod 3$ by setting

$$\begin{aligned}H_{1A,1}^{(12)}(\tau) &:= \frac{1}{24}\left(3h_1(\tau) + h_7(\tau)\right),\\ H_{1A,2}^{(12)}(\tau), H_{1A,10}^{(12)}(\tau) &:= \frac{1}{24}\left(h_2(\tau) + h_{10}(\tau)\right),\\ H_{1A,4}^{(12)}(\tau), H_{1A,8}^{(12)}(\tau) &:= \frac{1}{12}\left(h_4(\tau) + h_8(\tau)\right),\\ H_{1A,5}^{(12)}(\tau) &:= \frac{1}{24}\left(3h_5(\tau) + h_{11}(\tau)\right),\\ H_{1A,7}^{(12)}(\tau) &:= \frac{1}{24}\left(h_1(\tau) + 3h_7(\tau)\right),\\ H_{1A,11}^{(12)}(\tau) &:= \frac{1}{24}\left(h_5(\tau) + 3h_{11}(\tau)\right).\end{aligned} \tag{B.78}$$

For $r = 0 \mod 3$ set

$$H_{1A,r}^{(12)}(\tau) := \frac{1}{12}h_r(\tau), \tag{B.79}$$

and define $H_{2A,r}^{(12)}$ by requiring

$$H_{2A,r}^{(12)}(\tau) := -(-1)^r H_{1A,r}^{(12)}(\tau). \tag{B.80}$$

B.3.13 $\ell = 12+4$, $X = E_6^4$

We have $m^X = 12$, so the umbral McKay-Thompson series $H_g^{(12+4)} = (H_{g,r}^{(12+4)})$ associated to $g \in G^{(12+4)}$ is a 24-vector-valued function with components indexed by $r \in \mathbb{Z}/24\mathbb{Z}$. In addition to the identity $H_{g,r}^{(12+4)} = -H_{g,-r}^{(12+4)}$, we have $H_{g,r}^{(12+4)} = 0$ for $r \in \{2,3,6,9,10\}$, $H_{g,1}^{(12+4)} = H_{g,7}^{(12+4)}$, $H_{g,4}^{(12+4)} = H_{g,8}^{(12+4)}$, and $H_{g,5}^{(12+4)} = H_{g,11}^{(12+4)}$. Thus it suffices to specify the $H_{g,1}^{(12+4)}$, $H_{g,4}^{(12+4)}$ and $H_{g,5}^{(12+4)}$.

Recall (B.13). Also, set $S_1^{E_6}(\tau) := S_{12,1}(\tau) + S_{12,7}(\tau)$, and $S_5^{E_6}(\tau) := S_{12,5}(\tau) + S_{12,11}(\tau)$. For $r = 1$ define

$$\begin{aligned}
H_{1A,1}^{(12+4)}(\tau) &:= H_{1A,1}^{(12)}(\tau) + H_{1A,7}^{(12)}(\tau),\\
H_{2B,1}^{(12+4)}(\tau) &:= [-\tfrac{1}{48}]\left(H_{8AB,1}^{(6)}(\tau/2) - H_{8AB,5}^{(6)}(\tau/2)\right),\\
H_{4A,1}^{(12+4)}(\tau) &:= \frac{1}{S_1^{E_6}(\tau)^2 - S_5^{E_6}(\tau)^2}\left(-2\frac{\eta(2\tau)^8}{\eta(\tau)^4}S_1^{E_6}(\tau) + 8\frac{\eta(\tau)^4\eta(4\tau)^4}{\eta(2\tau)^4}S_5^{E_6}(\tau)\right),\\
H_{3A,1}^{(12+4)}(\tau) &:= [-\tfrac{1}{48}]\left(H_{3A,1}^{(6)}(\tau/2) - H_{3A,5}^{(6)}(\tau/2)\right),\\
H_{8AB,1}^{(12+4)}(\tau) &:= \frac{1}{S_1^{E_6}(\tau)^2 - S_5^{E_6}(\tau)^2}\left(-2F_{8AB,1}^{(12+4)}(\tau)S_1^{E_6}(\tau) + 12F_{8AB,5}^{(12+4)}(\tau/2)S_5^{E_6}(\tau)\right).
\end{aligned} \tag{B.81}$$

In the expression for $g \in 8AB$, we write $F_{8AB,1}^{(12+4)}$ for the unique modular form of weight 2 for $\Gamma_0(32)$ such that

$$F_{8AB,1}^{(12+4)}(\tau) = 1 + 12q + 4q^2 - 24q^5 - 16q^6 - 8q^8 + O(q^9), \tag{B.82}$$

and we write $F_{8AB,5}^{(12+4)}$ for the unique modular form of weight 2 for $\Gamma_0(64)$ such that

$$F_{8AB,5}^{(12+4)}(\tau) = 3q + 4q^3 + 6q^5 - 8q^7 - 9q^9 + 12q^{11} - 18q^{13} - 24q^{15} + O(q^{17}). \tag{B.83}$$

For $r = 4$ define

$$\begin{aligned}
H_{1A,4}^{(12+4)}(\tau) &:= H_{1A,4}^{(12)}(\tau) + H_{1A,8}^{(12)}(\tau),\\
H_{3A,4}^{(12+4)}(\tau) &:= H_{3A,2}^{(6)}(\tau/2) + H_{3A,4}^{(6)}(\tau/2),
\end{aligned} \tag{B.84}$$

and set $H_{g,4}^{(12+4)}(\tau) := 0$ for $g \in 2B \cup 4A \cup 8AB$.

For $r = 5$ define

$$\begin{aligned}
H_{1A,5}^{(12+4)}(\tau) &:= H_{1A,5}^{(12)}(\tau) + H_{1A,11}^{(12)}(\tau),\\
H_{2B,5}^{(12+4)}(\tau) &:= [-\tfrac{25}{48}]\left(H_{8AB,5}^{(6)}(\tau/2) - H_{8AB,1}^{(6)}(\tau/2)\right),\\
H_{4A,5}^{(12+4)}(\tau) &:= \frac{1}{S_1^{E_6}(\tau)^2 - S_5^{E_6}(\tau)^2}\left(2\frac{\eta(2\tau)^8}{\eta(\tau)^4}S_5^{E_6}(\tau) - 8\frac{\eta(\tau)^4\eta(4\tau)^4}{\eta(2\tau)^4}S_1^{E_6}(\tau)\right),\\
H_{3A,5}^{(12+4)}(\tau) &:= [-\tfrac{25}{48}]\left(H_{3A,5}^{(6)}(\tau/2) - H_{3A,1}^{(6)}(\tau/2)\right),\\
H_{8AB,5}^{(12+4)}(\tau) &:= \frac{1}{S_1^{E_6}(\tau)^2 - S_5^{E_6}(\tau)^2}\left(2F_{8AB,1}^{(12+4)}(\tau)S_5^{E_6}(\tau) - 12F_{8AB,5}^{(12+4)}(\tau/2)S_1^{E_6}(\tau)\right).
\end{aligned} \tag{B.85}$$

Finally, define $H^{(12+4)}_{g,r}$ for $g \in 2A \cup 6A$ by setting

$$\begin{aligned} H^{(12+4)}_{2A,r}(\tau) &:= -(-1)^r H^{(12+4)}_{1A,r}(\tau), \\ H^{(12+4)}_{6A,r}(\tau) &:= -(-1)^r H^{(12+4)}_{3A,r}(\tau). \end{aligned} \tag{B.86}$$

B.3.14 $\ell = 13$, $X = A_{12}^2$

We have $m^X = 13$, so the umbral McKay-Thompson series $H^{(13)}_g = (H^{(13)}_{g,r})$ associated to $g \in G^{(13)} = G^X \simeq \mathbb{Z}/4\mathbb{Z}$ is a 26-vector-valued function, with components indexed by $r \in \mathbb{Z}/26\mathbb{Z}$.

Define $H^{(13)}_g = (H^{(13)}_{g,r})$ for $g \in G^{(13)}$ by requiring that

$$\psi^{(13)}_g(\tau,z) = -\chi^{(13)}_g \mu^0_{13,0}(\tau,z) - \bar{\chi}^{(13)}_g \mu^1_{13,0}(\tau,z) + \sum_{r \mod 26} H^{(13)}_{g,r}(\tau)\theta_{13,r}(\tau,z), \tag{B.87}$$

where $\chi^{(13)}_g := \chi^{X_A}_g$ and $\bar{\chi}^{(13)}_g := \bar{\chi}^{X_A}_g$ (cf. Table 28), and the $\psi^{(13)}_g$ are meromorphic Jacobi forms of weight 1 and index 13 given explicitly in Table 42.

Table 42: Character Values and Meromorphic Jacobi Forms for $\ell = 13$, $X = A_{12}^2$

$[g]$	$\chi^{(13)}_g$	$\bar{\chi}^{(13)}_g$	$\psi^{(13)}_g(\tau,z)$
1A	2	2	$2i\theta_1(\tau,6z)\theta_1(\tau,z)^{-1}\theta_1(\tau,3z)^{-1}\eta(\tau)^3$
2A	-2	2	$-2i\theta_1(\tau,6z)\theta_2(\tau,z)^{-1}\theta_2(\tau,3z)^{-1}\eta(\tau)^3$
4A	0	0	cf. (B.88)

$$\psi^{(13)}_{4AB}(\tau,z) := -i\theta_2(\tau,6z)\frac{\theta_1(\tau,z+\frac14)\theta_1(\tau,3z+\frac14) - \theta_1(\tau,z-\frac14)\theta_1(\tau,3z-\frac14)}{\theta_2(2\tau,2z)\theta_2(2\tau,6z)}\frac{\eta(2\tau)^2}{\eta(\tau)} \tag{B.88}$$

For use later on we note that $\psi^{(13)}_{1A} = -2\Psi_{1,1}\varphi^{(13)}_1$, where

$$\varphi^{(13)}_1(\tau,z) := \frac{\theta_1(\tau,z)\theta_1(\tau,6z)}{\theta_1(\tau,2z)\theta_1(\tau,3z)}. \tag{B.89}$$

B.3.15 $\ell = 14 + 7$, $X = D_8^3$

We have $m^X = 14$, so the umbral McKay-Thompson series $H^{(14+7)}_g = (H^{(14+7)}_{g,r})$ associated to $g \in G^{(14+7)}$ is a 28-vector-valued function with components indexed by $r \in \mathbb{Z}/28\mathbb{Z}$. We have $H^{(14+7)}_{g,r} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H^{(14+7)}_{g,r}$ for r odd. Observing that $H^{(14+7)}_{g,r} = -H^{(14+7)}_{g,-r}$ we may determine $H^{(14+7)}_g$ by requiring that

$$\psi^{(7/2)}_g(\tau,z) = -2\bar{\chi}^{(7/2)}_g i\mu_{7/2,0}(\tau,z) + \sum_{\substack{r\in\mathbb{Z}+1/2 \\ r \mod 7}} e(-r/2)H^{(14+7)}_{g,2r}(\tau)\theta_{7/2,r}(\tau,z), \tag{B.90}$$

where $\bar{\chi}^{(7/2)}_g := \bar{\chi}^{X_D}_g$ is the number of fixed points of $g \in G^{(14+7)} \simeq S_3$ in the defining permutation representation on 3 points. The $\psi^{(7/2)}_g$ are the meromorphic Jacobi forms of weight 1 and index 7/2 defined in Table 43.

Table 43: Character Values and Meromorphic Jacobi Forms for $\ell = 14+7$, $X = D_8^3$

$[g]$	$\bar{\chi}_g^{(7/2)}$	$\psi_g^{(7/2)}(\tau,z)$
1A	3	$2i\theta_1(\tau,3z)\theta_1(\tau,z)^{-2}\eta(\tau)^3$
2A	1	$2i\theta_2(\tau,3z)\theta_1(\tau,z)^{-1}\theta_2(\tau,z)^{-1}\eta(\tau)^3$
3A	0	$-2i\theta_1(\tau,z)\theta_1(\tau,3z)\theta_1(3\tau,3z)^{-1}\eta(3\tau)$

B.3.16 $\ell = 16$, $X = A_{15}D_9$

We have $m^X = 16$, so the umbral McKay-Thompson series $H_g^{(16)} = (H_{g,r}^{(16)})$ associated to $g \in G^{(16)} \simeq \mathbb{Z}/2\mathbb{Z}$ is a 32-vector-valued function with components indexed by $r \in \mathbb{Z}/32\mathbb{Z}$. We have $H_{g,r}^{(16)} = -H_{g,-r}^{(16)}$, so it suffices to specify the $H_{g,r}^{(16)}$ for $1 \leq r \leq 15$.

To define $H_g^{(16)} = (H_{g,r}^{(16)})$ for $g = e$, first define $h(\tau) = (h_r(\tau))$ by requiring that

$$-6\Psi_{1,1}(\tau,z)\left(\varphi_1^{(16)}(\tau,z) + \frac{1}{2}\varphi_2^{(16)}(\tau,z)\right) = -24\mu_{16,0}(\tau,z) + \sum_{r \bmod 32} h_r(\tau)\theta_{16,r}(\tau,z), \tag{B.91}$$

where

$$\begin{aligned}\varphi_1^{(16)}(\tau,z) &:= 8\varphi_1^{(4)}(\tau,z)\varphi_1^{(13)}(\tau,z) - \varphi_1^{(5)}(\tau,z)\varphi_1^{(12)}(\tau,z) + \varphi_1^{(7)}(\tau,z)\varphi_1^{(10)}(\tau,z),\\ \varphi_2^{(16)}(\tau,z) &:= 12\varphi_1^{(4)}(\tau,z)\varphi_1^{(13)}(\tau,z) - \varphi_1^{(5)}(\tau,z)\varphi_1^{(12)}(\tau,z) - 3\varphi_1^{(16)}(\tau,z).\end{aligned} \tag{B.92}$$

(Cf. (B.35), (B.39), (B.54), (B.69), (B.77), (B.89).) Now define the $H_{1A,r}^{(16)}$ by setting

$$H_{1A,r}^{(16)}(\tau) := \frac{1}{12}h_r(\tau) \tag{B.93}$$

for r odd. For r even, $2 \leq r \leq 14$, use

$$H_{1A,r}^{(16)}(\tau) := \frac{1}{24}\left(h_r(\tau) + h_{16-r}(\tau)\right). \tag{B.94}$$

Define $H_{2A,r}^{(16)}$ by requiring

$$H_{2A,r}^{(16)}(\tau) := -(-1)^r H_{1A,r}^{(16)}(\tau). \tag{B.95}$$

B.3.17 $\ell = 18$, $X = A_{17}E_7$

We have $m^X = 18$, so the umbral McKay-Thompson series $H_g^{(18)} = (H_{g,r}^{(18)})$ associated to $g \in G^{(18)} \simeq \mathbb{Z}/2\mathbb{Z}$ is a 36-vector-valued function with components indexed by $r \in \mathbb{Z}/36\mathbb{Z}$. We have $H_{g,r}^{(18)} = -H_{g,-r}^{(18)}$, so it suffices to specify the $H_{g,r}^{(18)}$ for $1 \leq r \leq 17$.

To define $H_g^{(18)} = (H_{g,r}^{(18)})$ for $g = e$, first define $h(\tau) = (h_r(\tau))$ by requiring that

$$-24\Psi_{1,1}(\tau,z)\phi^{(18)}(\tau,z) = -24\mu_{18,0}(\tau,z) + \sum_{r \bmod 36} h_r(\tau)\theta_{18,r}(\tau,z), \tag{B.96}$$

where

$$\phi^{(18)} := \frac{1}{12}\left(\varphi_1^{(18)} + \frac{1}{3}\varphi_3^{(18)} + 4\frac{\theta_1^{12}}{\eta^{12}}\left(\varphi_1^{(12)} + 2\varphi_2^{(12)} + \frac{1}{3}\varphi_3^{(12)}\right)\right). \tag{B.97}$$

For the definition of $\phi^{(18)}$ we require

$$\begin{aligned}
\varphi_2^{(9)}(\tau,z) &:= \varphi_1^{(4)}(\tau,z)\varphi_1^{(6)}(\tau,z) - 4\varphi_1^{(5)}(\tau,z)^2 - 4\varphi_1^{(9)}(\tau,z),\\
\varphi_1^{(11)}(\tau,z) &:= 3\varphi_1^{(5)}(\tau,z)\varphi_1^{(7)}(\tau,z) + 2\varphi_1^{(3)}(\tau,z)\varphi_1^{(9)}(\tau,z) - \varphi_1^{(4)}(\tau,z)\varphi_1^{(8)}(\tau,z),\\
\varphi_3^{(12)}(\tau,z) &:= \varphi_1^{(4)}(\tau,z)\varphi_2^{(9)}(\tau,z),\\
\varphi_1^{(14)}(\tau,z) &:= 3\varphi_1^{(5)}(\tau,z)\varphi_1^{(10)}(\tau,z) + \varphi_1^{(3)}(\tau,z)\varphi_1^{(12)}(\tau,z) - 4\varphi_1^{(4)}(\tau,z)\varphi_1^{(11)}(\tau,z),\\
\varphi_1^{(15)}(\tau,z) &:= \varphi_1^{(5)}(\tau,z)\varphi_1^{(11)}(\tau,z) + 6\varphi_1^{(3)}(\tau,z)\varphi_1^{(13)}(\tau,z) - \varphi_1^{(4)}(\tau,z)\varphi_1^{(12)}(\tau,z),\\
\varphi_2^{(15)}(\tau,z) &:= \varphi_1^{(4)}(\tau,z)\varphi_1^{(12)}(\tau,z) - 2\varphi_1^{(5)}(\tau,z)\varphi_1^{(11)}(\tau,z) - 2\varphi_1^{(15)}(\tau,z),\\
\varphi_1^{(18)}(\tau,z) &:= \varphi_1^{(5)}(\tau,z)\varphi_1^{(14)}(\tau,z) + 3\varphi_1^{(3)}(\tau,z)\varphi_1^{(16)}(\tau,z) - 4\varphi_1^{(4)}(\tau,z)\varphi_1^{(15)}(\tau,z),\\
\varphi_3^{(18)}(\tau,z) &:= \varphi_1^{(4)}(\tau,z)\varphi_2^{(15)}(\tau,z),
\end{aligned} \tag{B.98}$$

in addition to the other $\varphi_k^{(m)}$ that have appeared already. Now define the $H_{1A,r}^{(18)}$ by setting

$$H_{1A,r}^{(18)}(\tau) := \frac{1}{24}h_r(\tau) \tag{B.99}$$

for r even. For r odd, use

$$\begin{aligned}
H_{1A,1}^{(18)}(\tau) &:= \frac{1}{24}\left(2h_1(\tau) + h_{17}(\tau)\right),\\
H_{1A,3}^{(18)}(\tau) &:= \frac{1}{24}\left(h_3(\tau) + h_9(\tau)\right),\\
H_{1A,5}^{(18)}(\tau) &:= \frac{1}{24}\left(2h_5(\tau) + h_{13}(\tau)\right),\\
H_{1A,7}^{(18)}(\tau) &:= \frac{1}{24}\left(2h_7(\tau) + h_{11}(\tau)\right),\\
H_{1A,9}^{(18)}(\tau) &:= \frac{1}{24}\left(h_3(\tau) + 2h_9(\tau) + h_{15}(\tau)\right),\\
H_{1A,11}^{(18)}(\tau) &:= \frac{1}{24}\left(h_7(\tau) + 2h_{11}(\tau)\right),\\
H_{1A,13}^{(18)}(\tau) &:= \frac{1}{24}\left(h_5(\tau) + 2h_{13}(\tau)\right),\\
H_{1A,15}^{(18)}(\tau) &:= \frac{1}{24}\left(h_{15}(\tau) + h_9(\tau)\right),\\
H_{1A,17}^{(18)}(\tau) &:= \frac{1}{24}\left(h_1(\tau) + 2h_{17}(\tau)\right).
\end{aligned} \tag{B.100}$$

Define $H_{2A,r}^{(18)}$ in the usual way for root systems with a type A component, by requiring

$$H_{2A,r}^{(18)}(\tau) := -(-1)^r H_{1A,r}^{(18)}(\tau). \tag{B.101}$$

B.3.18 $\ell = 18+9$, $X = D_{10}E_7^2$

We have $m^X = 18$, so the umbral McKay-Thompson series $H_g^{(18+9)} = (H_{g,r}^{(18+9)})$ associated to $g \in G^{(18+9)} \simeq \mathbb{Z}/2\mathbb{Z}$ is a 36-vector-valued function with components indexed by $r \in \mathbb{Z}/36\mathbb{Z}$. We have $H_{g,r}^{(18+9)} = -H_{g,-r}^{(18+9)}$, $H_{g,r}^{(18+9)} = H_{g,18-r}^{(18+9)}$ for $1 \leq r \leq 17$, and $H_{g,r}^{(18+9)} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H_{g,r}^{(18+9)}$ for $r \in \{1,3,5,7,9\}$.

Define

$$\begin{aligned} H_{1A,r}^{(18+9)}(\tau) &:= H_{1A,r}^{(18)}(\tau) + H_{1A,18-r}^{(18)}(\tau), \\ H_{2A,r}^{(18+9)}(\tau) &:= H_{1A,r}^{(18)}(\tau) - H_{1A,18-r}^{(18)}(\tau), \end{aligned} \tag{B.102}$$

for $r \in \{1,3,5,7,9\}$.

B.3.19 $\ell = 22+11$, $X = D_{12}^2$

We have $m^X = 22$, so the umbral McKay-Thompson series $H_g^{(22+11)} = (H_{g,r}^{(22+11)})$ associated to $g \in G^{(22+11)} \simeq \mathbb{Z}/2\mathbb{Z}$ is a 44-vector-valued function with components indexed by $r \in \mathbb{Z}/44\mathbb{Z}$. We have $H_{g,r}^{(22+11)} = -H_{g,-r}^{(22+11)}$ and $H_{g,r}^{(22+11)} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H_{g,r}^{(22+11)}$ for r odd. Observing that $H_{g,r}^{(22+11)} = -H_{g,-r}^{(22+11)}$ we may determine $H_g^{(22+11)}$ by requiring that

$$\psi_g^{(11/2)}(\tau,z) = -2\bar{\chi}_g^{(11/2)} i\mu_{11/2,0}(\tau,z) + \sum_{\substack{r \in \mathbb{Z}+1/2 \\ r \mod 11}} e(-r/2) H_{g,2r}^{(22+11)}(\tau)\theta_{11/2,r}(\tau,z), \tag{B.103}$$

where $\bar{\chi}_{1A}^{(11/2)} := 2$, $\bar{\chi}_{2A}^{(11/2)} := 0$, and the $\psi_g^{(11/2)}$ are the meromorphic Jacobi forms of weight 1 and index 11/2 defined as follows.

$$\begin{aligned} \psi_{1A}^{(11/2)}(\tau,z) &:= 2i\frac{\theta_1(\tau,4z)}{\theta_1(\tau,z)\theta_1(\tau,2z)}\eta(\tau)^3 \\ \psi_{2A}^{(11/2)}(\tau,z) &:= -2i\frac{\theta_1(\tau,4z)}{\theta_2(\tau,z)\theta_2(\tau,2z)}\eta(\tau)^3 \end{aligned} \tag{B.104}$$

B.3.20 $\ell = 25$, $X = A_{24}$

We have $m^X = 25$, so for $g \in G^{(25)} \simeq \mathbb{Z}/2\mathbb{Z}$, the associated umbral McKay-Thompson series $H_g^{(25)} = (H_{g,r}^{(25)})$ is a 50-vector-valued function, with components indexed by $r \in \mathbb{Z}/50\mathbb{Z}$, satisfying $H_{g,r}^{(25)} = -H_{g,-r}^{(25)}$, and in particular, $H_{g,r}^{(25)} = 0$ for $r = 0 \mod 25$. So it suffices to specify the $H_{g,r}^{(25)}$ for $1 \leq r \leq 24$.

Define $H_g^{(25)} = (H_{g,r}^{(25)})$ for $g = e$ by requiring that

$$-\Psi_{1,1}(\tau,z)\varphi_1^{(25)}(\tau,z) = -\mu_{25,0}(\tau,z) + \sum_{r \mod 50} H_{e,r}^{(25)}(\tau)\theta_{25,r}(\tau,z), \tag{B.105}$$

where

$$\varphi_1^{(25)}(\tau,z) := \frac{1}{2}\varphi_1^{(5)}(\tau,z)\varphi_1^{(21)}(\tau,z) - \varphi_1^{(7)}(\tau,z)\varphi_1^{(19)}(\tau,z) + \frac{1}{2}\varphi_1^{(13)}(\tau,z)^2. \tag{B.106}$$

For the definition of $\varphi_1^{(25)}$ we require

$$\begin{aligned}
\varphi_1^{(17)}(\tau,z) &:= 4\varphi_1^{(5)}(\tau,z)\varphi_1^{(13)}(\tau,z) - \varphi_1^{(9)}(\tau,z)^2,\\
\varphi_1^{(19)}(\tau,z) &:= \varphi_1^{(4)}(\tau,z)\varphi_1^{(16)}(\tau,z) + 2\varphi_1^{(7)}(\tau,z)\varphi_1^{(13)}(\tau,z) - \varphi_1^{(5)}(\tau,z)\varphi_1^{(15)}(\tau,z),\\
\varphi_1^{(21)}(\tau,z) &:= \varphi_1^{(5)}(\tau,z)\varphi_1^{(17)}(\tau,z) - 2\varphi_1^{(9)}(\tau,z)\varphi_1^{(13)}(\tau,z),
\end{aligned} \tag{B.107}$$

in addition to the other $\varphi_k^{(m)}$ that have appeared already. Define $H_{2A,r}^{(25)}$ in the usual way for root systems with a type A component, by requiring

$$H_{2A,r}^{(18)}(\tau) := -(-1)^r H_{1A,r}^{(18)}(\tau). \tag{B.108}$$

B.3.21 $\ell = 30+15$, $X = D_{16}E_8$

We have $m^X = 30$, so the umbral McKay-Thompson series $H_g^{(30+15)} = (H_{g,r}^{(30+15)})$ associated to $g \in G^{(30+15)} = \{e\}$ is a 60-vector-valued function with components indexed by $r \in \mathbb{Z}/60\mathbb{Z}$. We have $H_{e,r}^{(30+15)} = -H_{e,-r}^{(30+15)}$, $H_{e,r}^{(30+15)} = H_{e,30-r}^{(30+15)}$ for $1 \le r \le 29$, and $H_{e,r}^{(30+15)} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H_{e,r}^{(30+15)}$ for $r \in \{1,3,5,7,9,11,13,15\}$.

Define

$$\begin{aligned}
H_{1A,1}^{(30+15)}(\tau) &:= \frac{1}{2}\left(H_{1A,1}^{(30+6,10,15)} + [-\tfrac{1}{120}]H_{3A,1}^{(10+5)}(\tau/3)\right),\\
H_{1A,3}^{(30+15)}(\tau) &:= [-\tfrac{9}{120}]H_{3A,3}^{(10+5)}(\tau/3),\\
H_{1A,5}^{(30+15)}(\tau) &:= [-\tfrac{25}{120}]H_{3A,5}^{(10+5)}(\tau/3),\\
H_{1A,7}^{(30+15)}(\tau) &:= \frac{1}{2}\left(H_{1A,7}^{(30+6,10,15)} + [-\tfrac{49}{120}]H_{3A,3}^{(10+5)}(\tau/3)\right),\\
H_{1A,11}^{(30+15)}(\tau) &:= \frac{1}{2}\left(H_{1A,1}^{(30+6,10,15)} - [-\tfrac{1}{120}]H_{3A,1}^{(10+5)}(\tau/3)\right),\\
H_{1A,13}^{(30+15)}(\tau) &:= \frac{1}{2}\left(H_{1A,7}^{(30+6,10,15)} - [-\tfrac{49}{120}]H_{3A,3}^{(10+5)}(\tau/3)\right),\\
H_{1A,15}^{(30+15)}(\tau) &:= -[-\tfrac{105}{120}]H_{3A,5}^{(10+5)}(\tau/3).
\end{aligned} \tag{B.109}$$

B.3.22 $\ell = 30+6,10,15$, $X = E_8^3$

We have $m^X = 30$, and $G^{(30+6,10,15)} = G^X \simeq S_3$. The umbral McKay-Thompson series $H^{(30+6,10,15)}$ is a 60-vector-valued function with components indexed by $r \in \mathbb{Z}/60\mathbb{Z}$. We have

$$H_{g,r}^{(30+6,10,15)}(\tau) = \begin{cases} \pm H_{g,1}^{(30+6,10,15)} & \text{if } r = \pm1, \pm11, \pm19, \pm29 \mod 60,\\ \pm H_{g,7}^{(30+6,10,15)} & \text{if } r = \pm7, \pm13, \pm17, \pm27 \mod 60,\\ 0 & \text{else,} \end{cases} \tag{B.110}$$

so it suffices to specify the $H^{(30+6,10,15)}_{g,r}$ for $r=1$ and $r=7$. These functions may be defined as follows.

$$\begin{aligned}
H^{(30+6,10,15)}_{1A,1} &:= -2\frac{1}{\eta(\tau)^2}\left(\sum_{k,l,m\geq 0}+\sum_{k,l,m<0}\right)(-1)^{k+l+m}q^{(k^2+l^2+m^2)/2+2(kl+lm+mk)+(k+l+m)/2+3/40}\\
H^{(30+6,10,15)}_{2A,1} &:= -2\frac{1}{\eta(2\tau)}\left(\sum_{k,m\geq 0}-\sum_{k,m<0}\right)(-1)^{k+m}q^{3k^2+m^2/2+4km+(2k+m)/2+3/40}\\
H^{(30+6,10,15)}_{3A,1} &:= -2\frac{\eta(\tau)}{\eta(3\tau)}\sum_{k\in\mathbb{Z}}(-1)^k q^{15k^2/2+3k/2+3/40}\\
H^{(30+6,10,15)}_{1A,7} &= -2\frac{1}{\eta(\tau)^2}\left(\sum_{k,l,m\geq 0}+\sum_{k,l,m<0}\right)(-1)^{k+l+m}q^{(k^2+l^2+m^2)/2+2(kl+lm+mk)+3(k+l+m)/2+27/40}\\
H^{(30+6,10,15)}_{2A,7} &= 2\frac{1}{\eta(2\tau)}\left(\sum_{k,m\geq 0}-\sum_{k,m<0}\right)(-1)^{k+m}q^{3k^2+m^2/2+4km+3(2k+m)/2+27/40}\\
H^{(30+6,10,15)}_{3A,7} &= -2\frac{\eta(\tau)}{\eta(3\tau)}\sum_{k\in\mathbb{Z}}(-1)^k q^{15k^2/2+9k/2+27/40}
\end{aligned} \tag{B.111}$$

B.3.23 $\ell = 46+23$, $X = D_{24}$

We have $m^X = 22$, and $G^{(46+23)} = \{e\}$. The umbral McKay-Thompson series $H^{(46+23)}_e = (H^{(46+23)}_{e,r})$ is a 92-vector-valued function with components indexed by $r \in \mathbb{Z}/92\mathbb{Z}$. We have $H^{(46+23)}_{e,r} = -H^{(46+23)}_{e,-r}$ and $H^{(46+23)}_{e,r} = 0$ for $r = 0 \mod 2$, so it suffices to specify the $H^{(46+23)}_{e,r}$ for r odd. Observing that $H^{(46+23)}_{e,r} = -H^{(46+23)}_{e,-r}$ we may determine $H^{(46+23)}_e$ by requiring that

$$\psi^{(23/2)}_e(\tau,z) = -2i\mu_{23/2,0}(\tau,z) + \sum_{\substack{r\in\mathbb{Z}+1/2\\ r \mod 23}} e(-r/2)H^{(46+23)}_{g,2r}(\tau)\theta_{23/2,r}(\tau,z), \tag{B.112}$$

where $\psi^{(23/2)}_e$ is the meromorphic Jacobi forms of weight 1 and index 23/2 defined by setting

$$\psi^{(23/2)}_e(\tau,z) := 2i\frac{\theta_1(\tau,6z)}{\theta_1(\tau,2z)\theta_1(\tau,3z)}\eta(\tau)^3. \tag{B.113}$$

B.4 Rademacher Sums

Let Γ_∞ denote the subgroup of upper-triangular matrices in $SL_2(\mathbb{Z})$. Given $\alpha\in\mathbb{R}$ and $\gamma\in SL_2(\mathbb{Z})$, define $\mathrm{r}^{[\alpha]}_{1/2}(\gamma,\tau) := 1$ if $\gamma\in\Gamma_\infty$. Otherwise, set

$$\mathrm{r}^{[\alpha]}_{1/2}(\gamma,\tau) := e(-\alpha(\gamma\tau-\gamma\infty))\sum_{k\geq 0}\frac{(2\pi i\alpha(\gamma\tau-\gamma\infty))^{n+1/2}}{\Gamma(n+3/2)}, \tag{B.114}$$

where $e(x) := e^{2\pi i x}$. Let n be a positive integer, and suppose that ν is a multiplier system for vector-valued modular forms of weight 1/2 on $\Gamma = \Gamma_0(n)$. Assume that $\nu = (\nu_{ij})$ satisfies $\nu_{11}(T) = e^{\pi i/2m}$, for some basis $\{\mathfrak{e}_i\}$, for some positive integer m, where $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. To this data, attach the Rademacher sum

$$R_{\Gamma,\nu}(\tau) := \lim_{K\to\infty} \sum_{\gamma\in\Gamma_\infty\backslash\Gamma_{K,K^2}} \nu(\gamma) e\left(-\frac{\gamma\tau}{4m}\right) \mathfrak{e}_1 \, \mathrm{j}(\gamma,\tau)^{1/2} \, \mathrm{r}_{1/2}^{[-1/4m]}(\gamma,\tau), \tag{B.115}$$

where $\Gamma_{K,K^2} := \left\{ \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma \mid 0 \le c < K, |d| < K^2 \right\}$, and $\mathrm{j}(\gamma,\tau) := (c\tau + d)^{-1}$ for $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. If the expression (B.115) converges then it defines a mock modular form of weight 1/2 for Γ whose shadow is given by an explicitly identifiable Poincaré series. We refer to [13] for a review of this, and to [53] for a more general and detailed discussion.

Convergence of (B.115) can be shown by rewriting the Fourier expansion as in [53, Theorem 2] in terms of a sum of Kloostermann sums weighted by Bessel functions. This expression converges at $w = 1/2$ by the analysis discussed at the end of §3, following the method of Hooley as adapted by Gannon. That analysis requires not only establishing that the expressions converge, but also explicitly bounding the rates of convergence.

For the special case that $X = A_8^3$ we require 8-vector-valued functions $\check{t}_g^{(9)} = (\check{t}_{g,r}^{(9)})$ for $g \in G^X$ with order 3 or 6. For such g, define $\check{t}_{g,r}^{(9)}$, for $0 < r < 9$, by setting

$$\check{t}_{3A,r}^{(9)}(\tau) := \begin{cases} 0, & \text{if } r \neq 0 \mod 3, \\ -\theta_{3,3}(\tau,0), & \text{if } r = 3, \\ \theta_{3,0}(\tau,0), & \text{if } r = 6, \end{cases} \tag{B.116}$$

in the case that g has order 3, and

$$\check{t}_{6A,r}^{(9)}(\tau) := \begin{cases} 0, & \text{if } r \neq 0 \mod 3, \\ -\theta_{3,3}(\tau,0), & \text{if } r = 3, \\ -\theta_{3,0}(\tau,0), & \text{if } r = 6, \end{cases} \tag{B.117}$$

when $o(g) = 6$. Here $\theta_{m,r}(\tau,z)$ is as defined in (B.5).

The following result is proved in [17], using an analysis of representations of the metaplectic double cover of $SL_2(\mathbb{Z})$.

Theorem B.1 ([17])**.** *Let X be a Niemeier root system and let $g \in G^X$. Assume that the Rademacher sum $R^X_{\Gamma_0(n_g),\check{\nu}_g^X}$ converges. If $X \neq A_8^3$, or if $X = A_8^3$ and $g \in G^X$ does not satisfy $o(g) = 0 \mod 3$, then we have*

$$\check{H}_g^X(\tau) = -2R^X_{\Gamma_0(n_g),\check{\nu}_g^X}. \tag{B.118}$$

If $X = A_8^3$ and $g \in G^X$ satisfies $o(g) = 0 \mod 3$ then

$$\check{H}_{g,r}^X(\tau) = -2R^X_{\Gamma_0(n_g),\check{\nu}_g^X}(\tau) + \check{t}_g^{(9)}(\tau). \tag{B.119}$$

The $X = A_1^{24}$ case of Theorem B.1 was proven first in [12], via different methods.

Abstract

We describe surprising relationships between automorphic forms of various kinds, imaginary quadratic number fields and a certain system of six finite groups that are parameterised naturally by the divisors of twelve. The Mathieu group correspondence recently discovered by Eguchi–Ooguri–Tachikawa is recovered as a special case. We introduce a notion of extremal Jacobi form and prove that it characterises the Jacobi forms arising by establishing a connection to critical values of Dirichlet series attached to modular forms of weight two. These extremal Jacobi forms are closely related to certain vector-valued mock modular forms studied recently by Dabholkar–Murthy–Zagier in connection with the physics of quantum black holes in string theory. In a manner similar to monstrous moonshine the automorphic forms we identify constitute evidence for the existence of infinite-dimensional graded modules for the six groups in our system. We formulate an umbral moonshine conjecture that is in direct analogy with the monstrous moonshine conjecture of Conway–Norton. Curiously, we find a number of Ramanujan's mock theta functions appearing as McKay–Thompson series. A new feature not apparent in the monstrous case is a property which allows us to predict the fields of definition of certain homogeneous submodules for the groups involved. For four of the groups in our system we find analogues of both the classical McKay correspondence and McKay's monstrous Dynkin diagram observation manifesting simultaneously and compatibly.

1 Introduction

The term *monstrous moonshine* was coined by Conway [1] in order to describe the unexpected and mysterious connections between the representation theory of the largest sporadic group—the *Fischer–Griess monster*, $\mathbb{M}$—and modular functions that stemmed from McKay's observation that $196883 + 1 = 196884$, where the summands on the left are degrees of irreducible representations of $\mathbb{M}$ and the number on the right is the coefficient of q in the Fourier expansion of the *elliptic modular invariant*

$$J(\tau) = \sum_{m \geq -1} a(m) q^m = q^{-1} + 196884q + 21493760q^2 + 864299970q^3 + \cdots . \tag{1.1}$$

Thompson expanded upon McKay's observation in [2] and conjectured the existence of an infinite-dimensional monster module

$$V = \bigoplus_{m \geq -1} V_m \tag{1.2}$$

with $\dim V_m = a(m)$ for all m. He also proposed [3] to consider the series, now known as *McKay–Thompson series*, given by

$$T_g(\tau) = \sum_{m \geq -1} \mathrm{tr}_{V_m}(g)\, q^m \tag{1.3}$$

for $g \in \mathbb{M}$, and detailed explorations [1] by Conway–Norton led to the astonishing *moonshine conjecture*:

> For each $g \in \mathbb{M}$ the function T_g is a principal modulus for some genus zero group Γ_g.

(A discrete group $\Gamma < PSL_2(\mathbb{R})$ is said to have *genus zero* if the Riemann surface $\Gamma \backslash \mathbb{H}$ is isomorphic to the Riemann sphere minus finitely many points, and a holomorphic function f on $\mathbb{H}$ is called a *principal modulus* for a genus zero group Γ if it generates the field of Γ-invariant functions on $\mathbb{H}$.)

Thompson's conjecture was verified by Atkin, Fong and Smith (cf. [4, 5]). A more constructive verification was obtained by Frenkel–Lepowsky–Meurman [6, 7] with the explicit construction of a monster module $V = V^\natural$ with graded dimension given by the Fourier expansion (1.1) of the elliptic modular invariant. They used *vertex operators*—structures originating in the dual resonance theory of particle physics and finding contemporaneous application [8, 9] to affine Lie algebras—to recover the non-associative *Griess algebra* structure (developed in the first proof [10] of the existence of the monster) from a subspace of $V^\natural$. Borcherds found a way to attach vertex operators to every element of $V^\natural$ and determined the precise sense in which these operators could be given a commutative associative composition law, and thus arrived at the notion of *vertex algebra* [11], an axiomatisation of the operator product expansion of chiral conformal field theory. The closely related notion of *vertex operator algebra (VOA)* was subsequently introduced by Frenkel–Lepowsky–Meurman [12] and they established that the monster is precisely the group of automorphisms of a VOA structure on $V^\natural$; the Frenkel–Lepowsky–Meurman construction of $V^\natural$ would ultimately prove to furnish the first example of an *orbifold conformal field theory*.

Borcherds introduced the notion of *generalised Kac–Moody algebra* in [13] and by using the VOA structure on $V^\natural$ was able to construct a particular example—the monster Lie algebra—and use the corresponding equivariant denominator identities to arrive at a proof [14] of the Conway–Norton moonshine conjectures. Thus by 1992 monstrous moonshine had already become a phenomenon encompassing elements of finite group theory, modular forms, vertex algebras and generalised Kac–Moody algebras, as well as aspects of conformal field theory and string theory.

Recently Eguchi–Ooguri–Tachikawa have presented evidence [15] for a new kind of moonshine involving the elliptic genus of $K3$ surfaces (the elliptic genus is a topological invariant and therefore independent of the choice of $K3$ surface) and the *largest Mathieu group* M_{24} (cf. §3.1). This connection between $K3$ surfaces and M_{24} becomes apparent only after decomposing the elliptic genus into characters of the $N = 4$ superconformal algebra (cf. [16, 17, 18]). This decomposition process (cf. §2.4) reveals the presence of a mock modular form of weight 1/2 (cf. §2.1) satisfying

$$H^{(2)}(\tau) = \sum_{n=0}^{\infty} c_1^{(2)}(n-1/8)q^{n-1/8} = 2q^{-1/8}(-1+45q+231q^2+770q^3+2277q^4+\cdots) \quad (1.4)$$

and one recognises here the dimensions of several irreducible representations of M_{24} (cf. Table 8).

One is soon led to follow the path forged by Thompson in the case of the monster: to suspect the existence of a graded infinite-dimensional M_{24}-module

$$K^{(2)} = \bigoplus_{n=0}^{\infty} K^{(2)}_{n-1/8} \quad (1.5)$$

with $\dim K^{(2)}_{n-1/8} = c^{(2)}(n-1/8)$ for $n \geq 1$, and to study the analogues $H_g^{(2)}$ of the monstrous McKay–Thompson series obtained by replacing $c^{(2)}(n-1/8) = \dim K^{(2)}_{n-1/8}$ with $\mathrm{tr}_{K^{(2)}_{n-1/8}}(g)$ in (1.4). This idea has been implemented successfully in [19, 20, 21, 22] and provides strong evidence for the existence of such an M_{24}-module $K^{(2)}$. A proof of the existence of $K^{(2)}$ has now been established in [23] although no explicit construction is yet known. In particular there is as yet no known analogue of the vertex operator algebra structure which conjecturally characterises [12] the monster module $V^\natural$.

The strong evidence in support of the M_{24} analogue of Thompson's conjecture invites us to consider the M_{24} analogue of the Conway–Norton moonshine conjectures—this will justify the use of the term moonshine in the M_{24} setting—except that it is not immediately obvious what the analogue should be. Whilst the McKay–Thompson series $H_g^{(2)}$ is a mock modular form of weight $1/2$ on some $\Gamma_g < SL_2(\mathbb{Z})$ for every g in M_{24} [22], it is not the case that Γ_g is a genus zero group for every g, and even if it were, there is no obvious sense in which one mock modular form of weight $1/2$ on some group can "generate" all the others, and thus no obvious analogue of the principal modulus property.

A solution to this problem—the formulation of the moonshine conjecture for M_{24}—was found in [24] (see also §5.2) via an extension of the program that was initiated in [25]; the antecedents of which include Rademacher's pioneering work [26] on the elliptic modular invariant $J(\tau)$, quantum gravity in three dimensions [27, 28, 29], the AdS/CFT correspondence in physics [30, 31, 32], and the application of *Rademacher sums* to these and other settings in string theory [33, 34, 35, 36, 37, 38, 39] (and in particular [40]). To explain the formulation of the moonshine conjecture for M_{24} we recall that in [25] a Rademacher sum $R_\Gamma(\tau)$ is defined for each discrete group $\Gamma < PSL_2(\mathbb{R})$ commensurable with the modular group in such a way as to naturally generalise Rademacher's Poincaré series-like expression for the elliptic modular invariant derived in [26]. It is then shown in [25] that a holomorphic function on the upper-half plane (with invariance group commensurable with $PSL_2(\mathbb{Z})$) is the principal modulus for its invariance group if and only if it coincides with the Rademacher sum attached to this group. Thus the genus property of monstrous moonshine may be reformulated:

> For each g in $\mathbb{M}$ we have $T_g = R_{\Gamma_g}$ where Γ_g is the invariance group of T_g.

Write $R_\Gamma^{(2)}$ to indicate a weight $1/2$ generalisation of the (weight 0) Rademacher sum construction R_Γ studied in [25]. (Note that a choice of multiplier system on Γ is also required.) Then a natural M_{24}-analogue of the Conway–Norton moonshine conjecture comes into view:

> For each g in M_{24} we have $H_g^{(2)} = R_{\Gamma_g}^{(2)}$ where Γ_g is the invariance group of $H_g^{(2)}$.

This statement is confirmed in [24] for the functions $H_g^{(2)}$ that are, at this point, conjecturally attached to M_{24} via the conjectural M_{24}-module $K^{(2)}$.

Through these results we come to envisage the possibility that both monstrous moonshine and the M_{24} observation of Eguchi–Ooguri–Tachikawa will eventually be understood as aspects of one underlying structure which will include finite groups, various kinds of automorphic forms, extended algebras and string theory, and will quite possibly be formulated in terms of the AdS/CFT correspondence in the context of some higher-dimensional string or gravitational theory.

In fact we can expect this *moonshine structure* to encompass more groups beyond the monster and M_{24}: In this paper we identify the M_{24} observation as one of a family of correspondences between finite groups and (vector-valued) mock modular forms, with each member in the family admitting a natural analogue of the Conway–Norton moonshine conjecture according to the philosophy of [25, 24] (see also [41]). For each ℓ in $\Lambda = \{2,3,4,5,7,13\}$—the set of positive integers ℓ such that $\ell - 1$ divides 12—we identify a distinguished Jacobi form $Z^{(\ell)}$, a finite group $G^{(\ell)}$ and a family of vector-valued mock modular forms $H_g^{(\ell)}$ for $g \in G^{(\ell)}$. The Jacobi forms $Z^{(\ell)}$ satisfy an *extremal* condition formulated in terms of unitary irreducible characters of the $N = 4$ superconformal algebra (cf. §2.5), the mock modular form $H^{(\ell)} = H_e^{(\ell)}$ is related to $Z^{(\ell)}$ as $H^{(2)}$ is to the elliptic genus of a $K3$ surface (cf. §§2.4,2.5), the Fourier coefficients of the *McKay–Thompson series* $H_g^{(\ell)}$ support the existence of an infinite-dimensional graded module $K^{(\ell)}$ for $G^{(\ell)}$ playing a rôle analogous to that of $K^{(2)}$ for $G^{(2)} \simeq M_{24}$ (cf. §5.1), and the following *umbral moonshine conjecture* is predicted to hold where $R_\Gamma^{(\ell)}$ is an $(\ell-1)$-vector-valued generalisation (cf. §5.2) of the Rademacher sum construction $R_\Gamma^{(2)}$ studied in [24].

> For each g in $G^{(\ell)}$ we have $H_g^{(\ell)} = R_{\Gamma_g}^{(\ell)}$ where Γ_g is the invariance group of $H_g^{(\ell)}$.

In addition to the above properties with monstrous analogues we find the following new *discriminant property*: The exponents of the powers of q having non-vanishing coefficient in the Fourier development of $H^{(\ell)}$ determine certain imaginary quadratic number fields and predict the existence of dual pairs of irreducible representations of $G^{(\ell)}$ that are defined over these fields and irreducible over $\mathbb{C}$. Moreover, these dual pairs consistently appear as irreducible constituents in homogeneous $G^{(\ell)}$-submodules of $K^{(\ell)}$ in such a way that the degree of the submodule determines the discriminant of the corresponding quadratic field (cf. §5.4).

A main result of this paper is Theorem 2.2, which states that the extremal condition formulated in §2.5 characterises the Jacobi forms $Z^{(\ell)}$ for $\ell \in \{2,3,4,5,7,13\}$. To achieve this we establish a result of independent interest, which also serves to illustrate the depth of the characterisation problem: We show in Theorem 2.3 that the existence of an extremal Jacobi of index $m-1$ implies the vanishing of $L(f,1)$ for all new forms f of weight 2 and level m, where $L(f,s)$ is the Dirichlet series naturally attached to f. According to the Birch–Swinnerton-Dyer conjecture the vanishing of $L(f,1)$ implies that the elliptic curve E_f, attached to f by Eichler–Shimura theory, has rational points of infinite order. Thus it is extremely unexpected that an extremal Jacobi form can exist for all but finitely many values of m, and using estimates [42] due to Ellenberg together with some explicit computations we are able to verify that the only possible values are those for which no non-zero weight 2 forms exist; i.e. $\Gamma_0(m)$ has genus zero. The last step in our proof of Theorem 2.2 is to check the finitely many corresponding finite dimensional spaces of Jacobi forms, for which useful bases have been determined by Gritsenko in [43]. In this we way obtain that the $Z^{(\ell)}$ for $\ell \in \{2,3,4,5,7,13\}$ are precisely the unique, up to scale, weak Jacobi forms of weight zero satisfying the extremal condition (2.37).

In contrast to the monstrous case the McKay–Thompson series $H_g^{(\ell)}$ arising here are mock modular forms, and these are typically not in fact modular but become so after *completion* with respect to a *shadow* function $S_g^{(\ell)}$. It turns out that all the McKay–Thompson series $H_g^{(\ell)}$ for fixed $\ell \in \Lambda$ have shadows that are (essentially) proportional to a single vector-valued *unary theta function* $S^{(\ell)}$ (cf. §2.2) and so it is in a sense the six *moonlight shadows* $S^{(\ell)}$ for $\ell \in \Lambda$ that provide the irreducible information required to uncover the structure that we reveal in this paper. We therefore refer to the phenomena investigated here as *umbral moonshine*.

According to the Oxford English Dictionary, a flame or light that is *lambent* is playing "lightly upon or gliding over a surface without burning it, like a 'tongue of fire'; shining with a soft clear light and without fierce heat." And since the light of umbral moonshine is apparently of this nature, we call the six values in $\Lambda = \{2,3,4,5,7,13\}$ *lambent*, and we refer to the index $\ell \in \Lambda$ as the *lambency* of the connections relating the *umbral group* $G^{(\ell)}$ to the *umbral forms* $Z^{(\ell)}$ and $H_g^{(\ell)}$.

The rest of this paper is organised as follows. In §2 we discuss properties of Jacobi forms, Siegel forms, mock modular forms and mock theta functions. We explain two closely related ways in which Jacobi forms determine mock modular forms, one involving the decomposition into characters of the $N = 4$ superconformal algebra and the other involving a decomposition of meromorphic Jacobi forms into mock modular forms following [44] and [45]. In §2.5 we introduce the Jacobi forms $Z^{(\ell)}$ of weight 0 and index $\ell - 1$ for lambent ℓ and their associated vector-valued mock modular forms $H^{(\ell)}$. We prove (Theorem 2.2) that these functions are characterized by the extremal property (2.37) and we establish the connection (Theorem 2.6) to critical values of automorphic L-functions. We note that the coefficients in the q-expansions of the mock modular forms $H^{(\ell)}$ appear to be connected to the dimensions of irreducible representations of groups $G^{(\ell)}$ which we introduce and study in §3. In §§3.5,3.6 we discuss the remarkable fact that some of these groups manifest both the McKay correspondence relating ADE Dynkin diagrams to finite subgroups of $SU(2)$ as well as a generalisation of his monstrous E_8 observation. In §4 we discuss analytic properties of the McKay–Thompson series $H_g^{(\ell)}$ which are obtained by twisting the mock modular forms $H^{(\ell)}$ by elements $g \in G^{(\ell)}$. We determine the proposed McKay–Thompson series

$H_g^{(\ell)} = \big(H_{g,r}^{(\ell)}\big)$ precisely in terms of modular forms of weight 2 for all but a few g occurring for $\ell \in \{7, 13\}$, and we find that we can identify many of the component functions $H_{g,r}^{(\ell)}$ either with ratios of products of eta functions or with classical mock theta functions introduced by Ramanujan (and others). In §5 we collect our observations into a set of conjectures. These include the analogue of Thompson's conjecture (cf. §5.1), the umbral counterpart to the Conway–Norton moonshine conjecture (cf. §5.2), and a precise formulation of the discriminant property mentioned above (cf. §5.4). In §5.5 we mention some possible connections between our results, the geometry of complex surfaces, and string theory.

Our conventions for modular forms appear in §A, the character tables of the umbral groups $G^{(\ell)}$ appear in §B, tables of Fourier coefficients of low degree for all the proposed McKay–Thompson series $H_g^{(\ell)}$ appear in §C, and tables describing the $G^{(\ell)}$-module structures implied (for low degree) by the $H_g^{(\ell)}$ are collected in §D.

It is important to mention that much of the data presented in the tables of §C was first derived using certain vector-valued generalisations of the Rademacher sum construction that was applied to the functions of monstrous moonshine in [25], and in [24] to the functions attached to M_{24} via the observation of Eguchi–Ooguri–Tachikawa. In particular, these vector-valued Rademacher sums played an indispensable rôle in helping us arrive at the groups $G^{(\ell)}$ specified in §3, especially for $\ell > 3$, and also allowed us to formulate and test hypotheses regarding the modularity of the (vector-valued) functions $H_g^{(\ell)}$, including eta product expressions and the occurrences of classical mock theta functions; considerations which ultimately developed into the discussion of §4. A detailed discussion of the Rademacher construction is beyond the scope of this article but a full treatment is to be the focus of forthcoming work. The fact that the Rademacher sum approach proved so powerful may be taken as strong evidence in support of the *umbral moonshine conjecture*, Conjecture 5.4.

2 Automorphic Forms

In this section we discuss the modular objects that play a rôle in the connection between mock modular forms and finite groups that we will develop later in the paper. We also establish our notation and describe various relationships between Jacobi forms, theta functions, and vector-valued mock modular forms, including mock theta functions.

In what follows we take τ in the upper half-plane $\mathbb{H}$ and $z \in \mathbb{C}$, and adopt the shorthand notation $e(x) = e^{2\pi i x}$. We also define $q = e(\tau)$ and $y = e(z)$ and write

$$\gamma\tau = \frac{a\tau + b}{c\tau + d}, \quad \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) \tag{2.1}$$

for the natural action of $SL_2(\mathbb{Z})$ on $\mathbb{H}$ and

$$\gamma(\tau, z) = \left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d} \right) \tag{2.2}$$

for the action of $SL_2(\mathbb{Z})$ on $\mathbb{H} \times \mathbb{C}$.

2.1 Mock Modular Forms

Mock theta functions were first introduced in 1920 by S. Ramanujan in his last letter to Hardy. This letter contained 17 examples divided into four of *order* 3, ten of *order* 5 and three of *order* 7. Ramanujan did not define what he meant by the term order and to this day there seems to be no universally agreed upon definition. In this paper we use the term order only as a historical label. Ramanujan wrote his mock theta functions as what he termed "Eulerian series" that today would be recognised as specialisations of q-hypergeometric series. A well studied example is the order 3 mock theta function

$$f(q) = 1 + \sum_{n=1}^{\infty} \frac{q^{n^2}}{(1+q)^2(1+q^2)^2 \cdots (1+q^n)^2} = \sum_{n=0}^{\infty} \frac{q^{n^2}}{(-q;q)_n^2} \ , \tag{2.3}$$

where we have introduced the *q-Pochhammer* symbol

$$(a;q)_n = \prod_{k=0}^{n-1} (1 - aq^k) \,. \tag{2.4}$$

Interest in and applications of mock theta functions has burgeoned during the last decade following the work of Zwegers [44] who found an intrinsic definition of mock theta functions and their near modular behavior, and many applications of his work can be found in combinatorics [46, 47], characters of infinite-dimensional Lie superalgebras [48, 49], topological field theory [50, 51, 52, 53], the computation of quantum invariants of three-dimensional manifolds [54], and the counting of black hole states in string theory [45]. Descriptions of this breakthrough and some of the history of mock theta functions can be found in [55], [56] and [57].

Mock theta function are now understood as a special case of more general objects known as mock modular forms. A holomorphic function $h(\tau)$ on $\mathbb{H}$ is called a *(weakly holomorphic) mock* *modular form* of weight k for a discrete group Γ (e.g. a congruence subgroup of $SL_2(\mathbb{Z})$) if it has at most exponential growth as $\tau \to \alpha$ for any $\alpha \in \mathbb{Q}$, and if there exists a holomorphic modular form $f(\tau)$ of weight $2-k$ on Γ such that the *completion* of h given by

$$\hat{h}(\tau) = h(\tau) + (4i)^{k-1} \int_{-\bar{\tau}}^{\infty} (z+\tau)^{-k} \overline{f(-\bar{z})} \mathrm{d}z, \tag{2.5}$$

is a (non-holomorphic) modular form of weight k for Γ for some multiplier system ν say. In this case the function f is called the *shadow* of the mock modular form h. Even though h is not a modular form, it is common practice to call ν the multiplier system of h. One can show that ν is the conjugate of the multiplier system of f. In most of the examples in this paper we will deal with vector-valued mock modular forms so that the completion in fact transforms as $\nu(\gamma)\hat{h}(\gamma\tau)(c\tau+d)^{-k} = \hat{h}(\tau)$ in case the weight is k for all $\gamma = \left(\begin{smallmatrix} * & * \\ c & d \end{smallmatrix}\right) \in \Gamma$ where ν is a matrix-valued function on Γ.

The completion $\hat{h}(\tau)$ satisfies interesting differential equations. For instance, completions of mock modular forms were identified as weak Maass forms (non-holomorphic modular forms which are eigenfunctions of the Laplace operator) in [46] as a part of their solution to the longstanding Andrews–Dragonette conjecture. Note that we have the identity

$$2^{1-k}\pi\Im(\tau)^k \frac{\partial \hat{h}(\tau)}{\partial \bar{\tau}} = -2\pi i \overline{f(\tau)} \tag{2.6}$$

when f is the shadow of h.

Thanks to Zweger's work we may define a *mock theta function* to be a q-series $h = \sum_n a_n q^n$ such that for some $\lambda \in \mathbb{Q}$ the assignment $\tau \mapsto q^\lambda h|_{q=e(\tau)}$ defines a mock modular form of weight $1/2$ whose shadow is a unary (i.e. attached to a quadratic form in one variable) theta series of weight $3/2$.

In this paper we add one more rôle for mock theta functions to the list mentioned earlier; namely we conjecture that specific sets of mock theta functions appear as McKay–Thompson series associated to (also conjectural) infinite-dimensional modules for a sequence of groups $G^{(\ell)}$ which we refer to as the *umbral groups* and label by the *lambent* integers $\ell \in \Lambda = \{2,3,4,5,7,13\}$, which are just those positive integers that are one greater than a divisor of 12.

Many of the mock theta functions that appear later in this paper appear either in Ramanujan's last letter to Hardy or in his lost notebook [58]. These include an order 2 mock theta function

$$\mu(q) = \sum_{n\geq 0} \frac{(-1)^n\, q^{n^2} (q;q^2)_n}{(-q^2;q^2)_n^2} \tag{2.7}$$

and an order 8 mock theta function

$$U_0(q) = \sum_{n\geq 0} \frac{q^{n^2}(-q;q^2)_n}{(-q^4;q^4)_n}, \tag{2.8}$$

both of which appear at lambency 2 in connection with $G^{(2)} \simeq M_{24}$. The function $f(q)$ of (2.3) together with

$$\begin{aligned}
\phi(q) &= 1 + \sum_{n=1}^{\infty} \frac{q^{n^2}}{(1+q^2)(1+q^4)\cdots(1+q^{2n})} \\
\chi(q) &= 1 + \sum_{n=1}^{\infty} \frac{q^{n^2}}{(1-q+q^2)(1-q^2+q^4)\cdots(1-q^n+q^{2n})} \\
\omega(q) &= \sum_{n=0}^{\infty} \frac{q^{2n(n+1)}}{(1-q)^2(1-q^3)^2\cdots(1-q^{2n+1})^2} \\
\rho(q) &= \sum_{n=0}^{\infty} \frac{q^{2n(n+1)}}{(1+q+q^2)(1+q^3+q^6)\cdots(1+q^{2n+1}+q^{4n+2})}
\end{aligned} \tag{2.9}$$

constitute five order 3 mock theta functions appearing at lambency 3, and the four order 10 mock theta functions

$$\begin{aligned}
\phi_{10}(q) &= \sum_{n=0}^{\infty} \frac{q^{n(n+1)/2}}{(q;q^2)_{n+1}} \\
\psi_{10}(q) &= \sum_{n=0}^{\infty} \frac{q^{(n+1)(n+2)/2}}{(q;q^2)_{n+1}} \\
X(q) &= \sum_{n=0}^{\infty} \frac{(-1)^n q^{n^2}}{(-q;q)_{2n}} \\
\chi_{10}(q) &= \sum_{n=0}^{\infty} \frac{(-1)^n q^{(n+1)^2}}{(-q;q)_{2n+1}}
\end{aligned} \tag{2.10}$$

appear at lambency 5.

More mock theta functions were found later by others. At lambency 4 we will encounter order 8 mock theta functions discussed in [59] with q-expansions

$$\begin{aligned}
S_0(\tau) &= \sum_{n\geq 0} \frac{q^{n^2}(-q;q^2)_n}{(-q^2;q^2)_n}\\
S_1(\tau) &= \sum_{n\geq 0} \frac{q^{n(n+2)}(-q;q^2)_n}{(-q^2;q^2)_n}\\
T_0(\tau) &= \sum_{n\geq 0} \frac{q^{(n+1)(n+2)}(-q^2;q^2)_n}{(-q;q^2)_n}\\
T_1(\tau) &= \sum_{n\geq 0} \frac{q^{n(n+1)}(-q^2;q^2)_n}{(-q;q^2)_n}.
\end{aligned} \tag{2.11}$$

It is curious to note that the order is divisible by the lambency in each example.

2.2 Jacobi Forms

We now discuss Jacobi forms following [60]. We say a holomorphic function $\phi : \mathbb{H}\times\mathbb{C}\to\mathbb{C}$ is an *unrestricted Jacobi form* of weight k and index m for $SL_2(\mathbb{Z})$ if it transforms under the Jacobi group $SL_2(\mathbb{Z})\ltimes\mathbb{Z}^2$ as

$$\phi(\tau,z) = (c\tau+d)^{-k} e(-m\tfrac{cz^2}{c\tau+d})\,\phi(\gamma(\tau,z)) \tag{2.12}$$

$$\phi(\tau,z) = e(m(\lambda^2\tau+2\lambda z))\,\phi(\tau,z+\lambda\tau+\mu) \tag{2.13}$$

where $\gamma\in SL_2(\mathbb{Z})$ and $\lambda,\mu\in\mathbb{Z}$. In what follows we refer to the transformations (2.12) and (2.13) as the *modular* and *elliptic* transformations, respectively. The invariance of $\phi(\tau,z)$ under $\tau\to\tau+1$ and $z\to z+1$ implies a Fourier expansion

$$\phi(\tau,z) = \sum_{n,r\in\mathbb{Z}} c(n,r)q^n y^r \tag{2.14}$$

and the elliptic transformation can be used to show that $c(n,r)$ depends only on the *discriminant* r^2-4mn and r mod $2m$, and so we have $c(n,r)=C(r^2-4mn,\tilde{r})$ for some function $D\mapsto C(D,\tilde{r})$ where $\tilde{r}\in\{-m,\dots,m-1\}$, for example. An unrestricted Jacobi form is called a *weak Jacobi form*, a *(strong) Jacobi form*, or a *Jacobi cusp form* according as the Fourier coefficients satisfy $c(n,r)=0$ whenever $n<0$, $C(D,\tilde{r})=0$ whenever $D>0$, or $C(D,\tilde{r})=0$ whenever $D\geq 0$, respectively. In a slight departure from [60] we denote the space of weak Jacobi forms of weight k and index m by $J_{k,m}$.

In what follows we will need two further generalisations of the above definitions. The first is straightforward and replaces $SL_2(\mathbb{Z})$ by a finite index subgroup $\Gamma \subset SL_2(\mathbb{Z})$ in the modular transformation law. The second is more subtle and leads to *meromorphic Jacobi forms* which obey the modular and elliptic transformation laws but are such that the functions $z \mapsto \phi(\tau, z)$ are allowed to have poles lying at values of $z \in \mathbb{C}$ that map to torsion points of the elliptic curve $\mathbb{C}/(\mathbb{Z}\tau + \mathbb{Z})$. Our treatment of meromorphic Jacobi forms follows [44] and [45].

A property of (weak) Jacobi forms that will be important for us later is that they admit an expansion in terms of the *index m theta functions*,

$$\theta_r^{(m)}(\tau, z) = \sum_{n\in\mathbb{Z}} q^{(2mn+r)^2/4m} y^{2mn+r}, \tag{2.15}$$

given by

$$\phi(\tau, z) = \sum_{r (\mathrm{mod}\ 2m)} \tilde{h}_r(\tau)\theta_r^{(m)}(\tau, z) \tag{2.16}$$

in case the index of ϕ is m, where the *theta-coefficients* $\tilde{h}_r(\tau)$ constitute the components of a vector-valued modular form of weight $k - 1/2$ when k is the weight of ϕ. Recall that a vector valued function $\tilde{h} = (\tilde{h}_r)$ is called a *vector-valued modular form* of weight k for $\Gamma \subset SL_2(\mathbb{Z})$ if

$$\tilde{h}_r(\tau) = \frac{1}{(c\tau + d)^k} \sum_s \nu_{rs}(\gamma)\tilde{h}_s(\tau) \tag{2.17}$$

for all $\gamma \in \Gamma$ and $\tau \in \mathbb{H}$ for some matrix-valued function $\nu = (\nu_{rs})$ on Γ called the *multiplier system* for $\tilde{h}$.

The modular transformation law (2.12) with $\gamma = -I_2$ implies that $\phi(\tau, -z) = (-1)^k\phi(\tau, z)$. Combining this with the identity $\theta_{-r}^{(m)}(\tau, z) = \theta_r^{(m)}(\tau, -z)$ we see that $\tilde{h}_r(\tau) = (-1)^k\tilde{h}_{-r}(\tau)$ and in particular we can recover a weak Jacobi form of weight k and index m from the $m - 1$ theta-coefficients $\{\tilde{h}_1, \cdots, \tilde{h}_{m-1}\}$ in case k is odd.

In what follows we will encounter only weight 0 and weight 1 Jacobi forms; a typical such form will be denoted by $\phi(\tau, z)$ or $\psi(\tau, z)$ according as the weight is 0 or 1 and we will write the theta-expansion of a weight 1 Jacobi form ψ as

$$\psi(\tau, z) = \sum_{r=1}^{m-1} \tilde{h}_r(\tau)\hat{\theta}_r^{(m)}(\tau, z) \tag{2.18}$$

where $\hat{\theta}_r^{(m)}(\tau, z) = \theta_{-r}^{(m)}(\tau, z) - \theta_r^{(m)}(\tau, z)$ (cf. (2.15)) for $r \in \{1, 2, \cdots, m - 1\}$.

2.3 Meromorphic Jacobi Forms

We now explain a connection between the vector-valued mock modular forms we shall consider in this paper and meromorphic Jacobi forms. We specialize our discussion to weight 1 meromorphic Jacobi forms of a particular form that arise in our pairing of Jacobi forms with groups $G^{(\ell)}$, and later in our computation of McKay–Thompson series; namely, we consider meromorphic weight 1 and index m Jacobi forms which can be written as

$$\psi(\tau,z)=\Psi_{1,1}(\tau,z)\phi(\tau,z) \tag{2.19}$$

for some weight 0 index $m-1$ (holomorphic) weak Jacobi form ϕ where $\Psi_{1,1}$ is the specific meromorphic Jacobi form of weight 1 and index 1 given by

$$\Psi_{1,1}(\tau,z)=-i\,\frac{\theta_1(\tau,2z)\,\eta(\tau)^3}{(\theta_1(\tau,z))^2}=\frac{y+1}{y-1}-(y^2-y^{-2})q+\cdots . \tag{2.20}$$

We note that $\psi(\tau,z)$ has a simple pole at $z=0$ with residue $\phi(\tau,0)/\pi i$. Since $\phi(\tau,z)$ is a weak Jacobi form of weight 0 the function $\tau\mapsto\phi(\tau,0)$ is a modular form of weight 0 (with no poles at any cusps) and is hence equal to a constant; we denote this constant by

$$\chi=\phi(\tau,0). \tag{2.21}$$

It was shown by Zwegers [44] that meromorphic Jacobi forms have a modified theta-expansion (cf. (2.16)) in terms of vector-valued mock modular forms; in [45] this expansion was recast as follows. Define the averaging operator

$$\mathrm{Av}^{(m)}\Big[F(y)\Big]=\sum_{k\in\mathbb{Z}}q^{mk^2}y^{2mk}F(q^ky) \tag{2.22}$$

which takes a function of $y=e(z)$ with polynomial growth and returns a function of z which transforms like an index m Jacobi form under the elliptic transformations (2.13). Now define the *polar part* of $\psi=\Psi_{1,1}\phi$ by

$$\psi^P(\tau,z)=\chi\mathrm{Av}^{(m)}\Big[\frac{y+1}{y-1}\Big] \tag{2.23}$$

where $\chi=\phi(\tau,0)$ and define the *finite part* of ψ by

$$\psi^F(\tau,z)=\psi(\tau,z)-\psi^P(\tau,z). \tag{2.24}$$

The term finite is appropriate because with the polar part subtracted the finite part no longer has a pole at $z = 0$.

It follows from the analysis in [45] that $\psi^F(\tau, z)$ is a weight 1 index m *mock Jacobi form*, meaning that it has a theta-expansion

$$\psi^F(\tau, z) = \sum_{r=1}^{m-1} h_r(\tau)\hat{\theta}_r^{(m)}(\tau, z) \tag{2.25}$$

(cf. (2.18)) where the theta-coefficients h_r comprise the components of a vector-valued mock modular form of weight 1/2.

In the above we have again used the fact that ψ, ψ^P and hence also ψ^F pick up a minus sign under the transformation $z \to -z$. Moreover, the vector-valued mock modular forms obtained in this way always have shadow function given by the *unary theta series*

$$S_r^{(m)}(\tau) = \frac{1}{2\pi i}\frac{\partial}{\partial z}\theta_r^{(m)}(\tau, z)\bigg|_{z=0} = \sum_{n\in\mathbb{Z}}(2mn + r)q^{(2mn+r)^2/4m}. \tag{2.26}$$

To see why this is so, and for later use, we introduce the functions

$$\mu_j^{(m)}(\tau, z) = (-1)^{1+2j}\sum_{k\in\mathbb{Z}} q^{mk^2}y^{2mk}\frac{(yq^k)^{-2j} + (yq^k)^{-2j+1} + \cdots + (yq^k)^{1+2j}}{1 - yq^k} \tag{2.27}$$

for m a positive integer and $2j \in \{0, 1, \ldots, m-1\}$. Note that $\mu_0^{(m)}(\tau, z)$ is proportional to the polar part of ψ, as identified in (2.23),

$$\mu_0^{(m)}(\tau, z) = \mathrm{Av}^{(m)}\Big[\frac{y+1}{y-1}\Big]. \tag{2.28}$$

Remark 2.1. The function $\mu_0^{(2)}$ is closely related to the Appell-Lerch sum $\mu(t, z)$ which features prominently in [44].

The $\mu_0^{(m)}$ enjoy the following relation to the modular group $SL_2(\mathbb{Z})$. Define the *completion* of $\mu_0^{(m)}(\tau, z)$ by setting

$$\hat{\mu}^{(m)}(\tau, \bar{\tau}, z) = \mu_0^{(m)}(\tau, z) + \frac{1}{\sqrt{2m}}\frac{1}{(4i)^{1/2}}\sum_{r=-m}^{m-1}\theta_r^{(m)}(\tau, z)\int_{-\bar{\tau}}^{i\infty}(z + \tau)^{-1/2}\overline{S_r^{(m)}(-\bar{z})}\,\mathrm{d}z. \tag{2.29}$$

Then $\hat{\mu}^{(m)}$ transforms like a Jacobi form of weight 1 and index m for $SL_2(\mathbb{Z})$ but is not holomorphic. Therefore, from the transformation of the polar part

$$\psi^P(\tau,z)=\chi\mu_0^{(m)}(\tau,z) \tag{2.30}$$

we see that the shadow of $h=(h_r)$ is given by $\chi S^{(m)}=\big(\chi S_r^{(m)}\big)$, as we claimed. This means that the vector-valued mock modular forms arising in this way are closely related to mock theta functions: By the definition given in §2.1 we have $h_r(\tau)=q^{\lambda}M_r$ for some $\lambda\in\mathbb{Q}$ with M_r a mock theta function.

2.4 Superconformal Algebra

In §2.3 we saw how to associate a vector-valued mock modular form (h_r) to a weight 1 meromorphic Jacobi form ψ satisfying $\psi=\Psi_{1,1}\phi$ for some weak Jacobi form ϕ via the theta-expansion of the finite part of ψ. It will develop that the weight 0 forms ϕ of relevance to us have a close relation to the representation theory of the 2-dimensional $N=4$ superconformal algebra. To see this recall (cf. [16, 17, 18]) that this algebra contains subalgebras isomorphic to the affine Lie algebra $\hat{\mathfrak{sl}}_2$ and the Virasoro algebra, and in a unitary representation the former of these acts with level $m-1$, for some integer $m>1$, and the latter with central charge $c=6(m-1)$, and the unitary irreducible highest weight representations $V_{h,j}^{(m)}$ are labelled by the two *quantum numbers* h and j which are the eigenvalues of L_0 and $\frac{1}{2}J_0^3$, respectively, when acting on the highest weight state. (We adopt a normalisation of the $SU(2)$ current J^3 such that the zero mode J_0^3 has integer eigenvalues.) In the Ramond sector of the superconformal algebra there are two types of highest weight representations: the *massless* (or *BPS*, *supersymmetric*) ones with $h=\frac{m-1}{4}$ and $j\in\{0,\frac{1}{2},\cdots,\frac{m-1}{2}\}$, and the *massive* (or *non-BPS*, *non-supersymmetric*) ones with $h>\frac{m-1}{4}$ and $j\in\{\frac{1}{2},1,\cdots,\frac{m-1}{2}\}$. Their *(Ramond) characters*, defined as

$$\mathrm{ch}_{h,j}^{(m)}(\tau,z)=\mathrm{tr}_{V_{h,j}^{(m)}}\left((-1)^{J_0^3}y^{J_0^3}q^{L_0-c/24}\right), \tag{2.31}$$

are given by

$$\mathrm{ch}^{(m)}_{\frac{m-1}{4},j}(\tau,z)=(\Psi_{1,1}(\tau,z))^{-1}\mu_j^{(m)}(\tau,z) \tag{2.32}$$

and

$$\mathrm{ch}_{h,j}^{(m)}(\tau,z)=(-1)^{2j+1}(\Psi_{1,1}(\tau,z))^{-1}\,q^{h-\frac{m-1}{4}-\frac{j^2}{m}}\,\hat\theta_{2j}^{(m)}(\tau,z) \tag{2.33}$$

in the massless and massive cases, respectively, [17] where the function $\mu_j^{(m)}(\tau,z)$ is defined as in (2.27) and $\hat\theta_r^{(m)}(\tau,z)$ is as in the sentence following (2.18).

We can use the above results to derive a decomposition of an arbitrary weight 0 index $m-1$

Jacobi form $\phi(\tau,z)$ into $N=4$ characters as follows. Set $\psi(\tau,z)=\Psi_{1,1}(\tau,z)\phi(\tau,z)$ as in §2.3 and write

$$h_r(\tau)=\sum_n c_r(n-r^2/4m)q^{n-r^2/4m} \tag{2.34}$$

for the Fourier expansion of the theta-coefficient h_r of the finite part ψ^F of ψ (cf. (2.25)). Then use (2.24), (2.25) and (2.30) along with (2.32) and (2.33) to obtain

$$\begin{aligned}\phi =&\chi\,\mathrm{ch}^{(m)}_{\frac{m-1}{4},0}+\sum_{r=1}^{m-1}(-1)^{r+1}c_r(-\tfrac{r^2}{4m})\left(\mathrm{ch}^{(m)}_{\frac{m-1}{4},\frac{r}{2}}+2\mathrm{ch}^{(m)}_{\frac{m-1}{4},\frac{r-1}{2}}+\mathrm{ch}^{(m)}_{\frac{m-1}{4},\frac{r-2}{2}}\right)\\ &+\sum_{r=1}^{m-1}(-1)^{r+1}\sum_{n=1}^{\infty}c_r(n-\tfrac{r^2}{4m})\,\mathrm{ch}^{(m)}_{\frac{m-1}{4}+n,\frac{r}{2}}\end{aligned} \tag{2.35}$$

where $\chi=\phi(\tau,0)$ is the constant such that $\chi S^{(m)}$ is the shadow of $h=(h_r)$ (cf. §2.3). In deriving (2.35) we have used the relation

$$\mu^{(m)}_{\frac{r-2}{2}}+2\mu^{(m)}_{\frac{r-1}{2}}+\mu^{(m)}_{\frac{r}{2}}=(-1)^{r+1}\,q^{-\frac{r^2}{4m}}\hat{\theta}^{(m)}_r \tag{2.36}$$

subject to the understanding that $\mu^{(m)}_{-\frac{1}{2}}=\mathrm{ch}^{(m)}_{\frac{m-1}{4},-\frac{1}{2}}=0$.

One way a weak Jacobi form of weight 0 and index $m-1$ having integer coefficients can arise in nature is as the elliptic genus of a 2-dimensional $N=4$ superconformal field theory with central charge $c=6(m-1)$. There is a unique weak Jacobi form of weight 0 and index 1 up to scale and this (suitably scaled) turns out to be the elliptic genus of a superconformal field theory attached to a $K3$ surface. Then the above analysis at $m=2$ recovers the mock modular form $H^{(2)}$ (the vectors have $m-1=1$ components in this case) exhibiting the connection to the Mathieu group M_{24} observed by Eguchi–Ooguri–Tachikawa in [15].

In the next section we will construct a distinguished family of extremal weight 0 weak Jacobi forms $\phi^{(\ell)}(\tau,z)$ with corresponding vector-valued weight 1/2 mock modular forms $H^{(\ell)}(\tau)$ according to the procedure (2.19-2.25) of §2.3. In §3 we will specify finite groups $G^{(\ell)}$ for which the forms $H^{(\ell)}$ will serve as generating functions for the graded dimensions of conjectural bi-graded infinite-dimensional $G^{(\ell)}$-modules.

2.5 Extremal Jacobi Forms

In this section we identify the significance of the divisors of 12 from the point of view of the $N=4$ superconformal algebra. We introduce the notion of an extremal (weak) Jacobi form of weight 0 and integral index and we prove that the space $J^{\mathrm{ext}}_{0,m-1}$ of extremal forms with index $m-1$ has dimension 1 if $m-1$ divides 12, and has dimension 0 otherwise. Several of the extremal Jacobi forms we identify have appeared earlier in the literature in the context of studying decompositions of elliptic genera of Calabi–Yau manifolds [43, 61, 48] and in a recent study of the connection between black hole counting in superstring theory and mock modular forms [45].

For m a positive integer and ϕ a weak Jacobi form with weight 0 and index $m-1$ say ϕ is *extremal* if it admits an expression

$$\phi = a_{\frac{m-1}{4},0}\mathrm{ch}^{(m)}_{\frac{m-1}{4},0} + a_{\frac{m-1}{4},\frac{1}{2}}\mathrm{ch}^{(m)}_{\frac{m-1}{4},\frac{1}{2}} + \sum_{0<r<m}\sum_{\substack{n\in\mathbb{Z}\\ r^2-4mn<0}} a_{\frac{m-1}{4}+n,\frac{r}{2}}\mathrm{ch}^{(m)}_{\frac{m-1}{4}+n,\frac{r}{2}} \tag{2.37}$$

for some $a_{h,j}\in\mathbb{C}$ (cf. (2.35)) where the $N=4$ characters are as defined in (2.32) and (2.33). Write $J^{\mathrm{ext}}_{0,m-1}$ for the subspace of $J_{0,m-1}$ consisting of extremal weak Jacobi forms. Note that the extremal condition restricts both the massless and massive $N=4$ representations that can appear, for generally there are non-zero massive characters $\mathrm{ch}^{(m)}_{\frac{m-1}{4}+n,\frac{r}{2}}$ with $r^2-4mn\geq 0$.

We observe here that the extremal condition has a very natural interpretation in terms of the mock modular forms of weight 1/2 attached to weak Jacobi forms of weight 0 via the procedure detailed in §2.3. By comparing with (2.35) we find that the condition (2.37) on a weak Jacobi form ϕ of index $m-1$ is equivalent to requiring that the corresponding vector-valued mock modular form (h_r) obtained from the theta-expansion (2.25) of the finite part of the weight 1 Jacobi form $\psi=\Psi_{1,1}\phi$ has a single polar term $q^{-\frac{1}{4m}}$ in the first component h_1 and has all other components vanishing as $\tau\to i\infty$.

Our main result in this section is the following characterisation of extremal Jacobi forms.

Theorem 2.2. *If m is a positive integer then* $\dim J^{\mathrm{ext}}_{0,m-1}=1$ *in case* $m-1$ *divides* 12 *and* $\dim J^{\mathrm{ext}}_{0,m-1}=0$ *otherwise.*

In preparation for the proof of Theorem 2.2 we now summarise (aspects of) a useful construction given in [43]. The graded ring

$$J_{0,*}=\bigoplus_{m\geq 1} J_{0,m-1} \tag{2.38}$$

of (weak) Jacobi forms of weight 0 and integral index has an ideal

$$J_{0,*}(q) = \bigoplus_{m>1} J_{0,m-1}(q) = \left\{ \phi \in J_{0,*} \mid \phi(\tau,z) = \sum_{\substack{n,r\in\mathbb{Z}\\ n>0}} c(n,r) q^n y^r \right\} \tag{2.39}$$

consisting of Jacobi forms that vanish in the limit as $\tau \to i\infty$ (i.e. have vanishing coefficient of $q^0 y^r$, for all r, in their Fourier development). This ideal is principal and generated by a weak Jacobi form of weight 0 and index 6 given by

$$\zeta(\tau,z) = \frac{\theta_1(\tau,z)^{12}}{\eta(\tau)^{12}} \tag{2.40}$$

(cf. §A for θ_1 and η). Gritsenko shows [43] that for any positive integer m the quotient $J_{0,m-1}/J_{0,m-1}(q)$ is a vector space of dimension $m-1$ admitting a basis consisting of weight 0 index $m-1$ weak Jacobi forms $\varphi_n^{(m)}$ (denoted $\psi_{0,m-1}^{(n)}$ in [43]) for $1 \leq n \leq m-1$ such that the coefficient of $q^0 y^k$ in $\varphi_n^{(m)}$ vanishes for $|k| > n$ but does not vanish for $|k| = n$. In fact Gritsenko works in the subring $J_{0,*}^{\mathbb{Z}}$ of Jacobi forms having integer Fourier coefficients and his $\varphi_n^{(m)}$ furnish a $\mathbb{Z}$-basis for the $\mathbb{Z}$-module $J_{0,*}^{\mathbb{Z}}/J_{0,*}^{\mathbb{Z}}(q)$.

We show now that there are no non-zero extremal Jacobi forms in the ideal $J_{0,*}(q)$.

Lemma 2.3. *If ϕ is an extremal weak Jacobi form belonging to $J_{0,*}(q)$ then $\phi = 0$.*

Proof. If ϕ belongs to $J_{0,*}(q)$ then the coefficients of $q^0 y^k$ in the Fourier development of ϕ vanish for all k. This implies the vanishing of $a_{\frac{m-1}{4},0}$ and $a_{\frac{m-1}{4},\frac{1}{2}}$ in (2.37) where $m-1$ is the index of ϕ, and this in turn implies that the meromorphic Jacobi form $\psi = \Psi_{1,1}\phi$ of weight 1 and index m coincides with its finite part $\psi = \psi^F = \sum_r h_r \hat{\theta}_r^{(m)}$ (cf. (2.21), (2.23), (2.25)) and has theta-coefficients h_r that remain bounded as $\tau \to i\infty$. In particular, ψ is a (strong) Jacobi form of weight 1 and integral index but the space of such forms vanishes according to [62], so ϕ must vanish also. ☐

As a consequence of Lemma 2.3 we obtain that there are no extremal Jacobi forms with vanishing massless contribution at spin $j = 1/2$.

Lemma 2.4. *If ϕ is an extremal weak Jacobi form of index $m-1$ such that $a_{\frac{m-1}{4},\frac{1}{2}} = 0$ in (2.37) then $\phi = 0$.*

Proof. If ϕ is of weight 0 and index $m-1$ satisfying (2.37) then $\phi = a + b(y + y^{-1}) + O(q)$ as

$\tau \to i\infty$ where $a = a_{\frac{m-1}{4},0}$ and $b = -a_{\frac{m-1}{4},\frac{1}{2}}$. Following [43] we set

$$\tilde{\phi}(\tau, z) = \exp(-8\pi^2(m-1)G_2(\tau)z^2)\phi(\tau, z) \tag{2.41}$$

where $G_2(\tau) = -\frac{1}{24} + \sum_{n>0} \sigma_1(n)q^n$ is the unique up to scale mock modular form of weight 2 for $SL_2(\mathbb{Z})$ (with shadow a constant function) and consider the *Taylor expansion* $\tilde{\phi}(\tau, z) = \sum_{n\geq 0} f_n(\tau)z^n$. Then $f_0(\tau) = \chi = a + 2b$ and more generally $f_n(\tau)$ is a modular form of weight n for $SL_2(\mathbb{Z})$. In particular $f_2(\tau) = 0$. On the other hand the constant term of $f_2(\tau)$ is $\frac{1}{3}\pi^2(m-1)\chi - 4\pi^2 b$ so $(m-1)\chi = 12b$. By hypothesis $b = 0$ so $\chi = 0$ and ϕ belongs to $J_{0,m-1}(q)$ and thus vanishes according to Lemma 2.3. □

Applying Lemma 2.4 we obtain that the dimension of $J^{\mathrm{ext}}_{0,m-1}$ is at most 1 for any m.

Proposition 2.5. *We have* $\dim J^{\mathrm{ext}}_{0,m-1} \leq 1$ *for any positive integer* m.

Proof. If ϕ' and ϕ'' are two elements of $J^{\mathrm{ext}}_{0,m-1}$ then there exists $c \in \mathbb{C}$ such that $\phi = \phi' - c\phi''$ is extremal and has vanishing $a_{\frac{m-1}{4},\frac{1}{2}}$ in (2.37). Then $\phi = 0$ according to Lemma 2.4 and thus ϕ' belongs to the linear span of ϕ''. □

We now present a result which ultimately shows that there are only finitely many m for which $J^{\mathrm{ext}}_{0,m-1} \neq \{0\}$, and also illustrates the depth of the characterisation problem. In preparation for it let us write $S_2(m)$ for the space of cusp forms of weight 2 for $\Gamma_0(m)$ and recall that $f \in S_2(m)$ is called a *newform* if it is a Hecke eigenform, satisfying $T(n)f = \lambda_f(n)f$ whenever $(n, m) = 1$ for some $\lambda_f(n) \in \mathbb{C}$, that is uniquely specified (up to scale) in $S_2(m)$ by its Hecke eigenvalues $\{\lambda_f(n) \mid (n, m) = 1\}$ (cf. [63, §IX.7]). Write $S_2^{\mathrm{new}}(m)$ for the subspace of $S_2(m)$ spanned by newforms. Given $f \in S_2(m)$ define $L(f, s) = \sum_{n>0} a_f(n)n^{-s}$ for $\Re(s) > 1$ when $f(\tau) = \sum_{n>0} a_f(n)q^n$. Then $L(f, s)$ is called the *Dirichlet L-function* attached to f and admits an analytic continuation to $s \in \mathbb{C}$ (cf. [63, §IX.4] or [64, §3.6].) To a newform f in $S_2(m)$ (i.e. a Hecke eigenform in $S_2^{\mathrm{new}}(m)$) Eichler–Shimura theory attaches an Elliptic curve E_f defined over $\mathbb{Q}$ (cf. [63, §XI.11]), and the Birch–Swinnerton-Dyer conjecture predicts that E_f has rational points of infinite order whenever $L(f, s)$ vanishes at $s = 1$ (cf. [65, 66]).

Theorem 2.6. *If* m *is a positive integer and* $J^{\mathrm{ext}}_{0,m-1} \neq \{0\}$ *then* $L(f, 1) = 0$ *for every* $f \in S_2^{\mathrm{new}}(m)$.

Proof. Let m be a positive integer. For $L = \sqrt{2m}\mathbb{Z}$ the spaces $H^+_{k,L}$ and S_{2-k,L^-} of [67, §3] are naturally isomorphic to $\mathbb{J}_{k+1/2,m}$ and $S^{\mathrm{skew}}_{5/2-k,m}$, respectively, where $\mathbb{J}_{k,m}$ denotes the space of weak (pure) mock Jacobi forms of weight k and index m (cf. [45, §7.2]) and $S^{\mathrm{skew}}_{k,m}$ denotes the space of cuspidal skew-holomorphic Jacobi forms of weight k and index m (cf. [68]). Translating the construction (3.9) of [67] into this language, and taking $k = 1/2$, we obtain a pairing

$$\{\cdot\,,\cdot\} : S^{\mathrm{skew}}_{2,m} \times \mathbb{J}_{1,m} \to \mathbb{C}. \tag{2.42}$$

If $J^{\mathrm{ext}}_{0,m-1} \neq \{0\}$ then let $\phi \in J^{\mathrm{ext}}_{0,m-1}$ be a non-zero extremal Jacobi form and set $\psi = \Psi_{1,1}\phi$ as in §2.3. Then the finite part ψ^F of ψ belongs to $\mathbb{J}_{1,m}$ and the shadow of ψ^F (cf. [45, §7.2]) is the cuspidal skew-holomorphic Jacobi form $\chi\sigma^{(m)} \in S^{\mathrm{skew}}_{2,m}$ where $\chi = \phi(\tau, 0)$ and

$$\sigma^{(m)}(\tau, z) = \sum_{r \bmod 2m} \overline{S^{(m)}_r(\tau)}\theta^{(m)}_r(\tau, z). \tag{2.43}$$

Consider the linear functional λ_ϕ on $S^{\mathrm{skew}}_{2,m}$ defined by setting $\lambda_\phi(\varphi) = \{\varphi, \psi^F\}$. According to the definition of (2.42) (i.e. (3.9) of [67]) we have

$$\lambda_\phi(\varphi) = C_m\langle\varphi, \chi\sigma^{(m)}\rangle \tag{2.44}$$

for some (non-zero) constant C_m (depending only on m) where $\langle\cdot\,,\cdot\rangle$ denotes the Petersson inner product on $S^{\mathrm{skew}}_{2,m}$ (cf. [68]). On the other hand, inspection reveals that $h_{\pm1}(\tau) = \mp a_{\frac{m-1}{4},\frac{1}{2}}q^{-1/4m}(1 + O(q))$ when $\psi^F = \sum_{r \bmod 2m} h_r\theta^{(m)}_r$ so

$$\lambda_\phi(\varphi) = -2a_{\frac{m-1}{4},\frac{1}{2}}C_\varphi(1, 1) \tag{2.45}$$

according to Proposition 3.5 of [67] where $\varphi(\tau, z) = \sum C_\varphi(\Delta, r)\bar{q}^{\Delta/4m}q^{r^2/4m}y^r$ is the Fourier expansion of φ (cf. [68]). Applying Lemma 2.4 we deduce from (2.45) that $\lambda_\phi(\varphi) = 0$ for $\varphi \in S^{\mathrm{skew}}_{2,m}$ if and only if $C_\varphi(1, 1) = 0$.

Now let f be a newform in $S_2(m)$. If $\Lambda(f, s) = (2\pi)^{-s}m^{s/2}\Gamma(s)L(f, s)$ then either $\Lambda(f, s) = \Lambda(f, 2-s)$ or $\Lambda(f, s) = -\Lambda(f, 2-s)$. In the latter case $L(f, 1)$ necessarily vanishes. In the former case Theorem 1 of [69] attaches a skew-holomorphic Jacobi form $\varphi_f \in P^{\mathrm{skew}}_{2,m}$ to f having the same eigenvalues as f under the Hecke operators $T(n)$ for $(n, m) = 1$. (See [69] for the action of Hecke operators on skew-holmorphic Jacobi forms.) Here $P^{\mathrm{skew}}_{2,m}$ denotes the subspace of $S^{\mathrm{skew}}_{2,m}$ spanned by cuspidal Hecke eigenforms which are not of the trivial type: say $\varphi \in S^{\mathrm{skew}}_{2,m}$ is of the *trivial type* if the Fourier coefficients $C_\varphi(\Delta, r)$ are non-vanishing only when Δ is a perfect square. Cusp forms of the trivial type are orthogonal to $P^{\mathrm{skew}}_{2,m}$ with respect to the Petersson inner product (cf. the proof of Theorem 3 in [69]) and $\sigma^{(m)}$ is a cusp form of the trivial type, so we have $\lambda_\phi(\varphi_f) = 0$ by virtue of (2.44) and hence $C_{\varphi_f}(1, 1) = 0$ according to the previous paragraph. The proposition now follows by taking $(\Delta, r) = (1, 1)$ in the formula at the bottom of p. 503 of [68]. ☐

Applying Theorem 2.6 we see, for example, that there are no non-zero extremal Jacobi forms of index 10, for it is known that $L(f, 1) \neq 0$ for $f = \eta(\tau)^2\eta(11\tau)^2 \in S_2(11)$. (Cf. [68, p. 504] where the corresponding Jacobi form φ_f is computed explicitly.)

Duke showed [70] that there is a constant C such that at least $Cm/\log^2 m$ newforms $f \in S_2(m)$ satisfy $L(f, 1) \neq 0$ when m is a sufficiently large prime, and Ellenberg proved an effective version of this result [42] that is valid also for composite m. We will apply the formulas of Ellenberg momentarily in order to deduce an upper bound on the m for which $J^{\rm ext}_{0,m-1} \neq \{0\}$, but since these formulas give better results for values of m with fewer divisors we first show that $J^{\rm ext}_{0,m-1}$ must vanish whenever m is divisible by more than one prime, and whenever $m = p^\nu$ is a prime power with $\nu > 2$.

Proposition 2.7. *If m is divisible by more than one prime then $J^{\rm ext}_{0,m-1} = \{0\}$.*

Proof. Suppose that $m = p^\nu d$ with p prime, $\nu > 0$, $d > 1$ and $(p, d) = 1$. With notation as in the proof of Theorem 2.6 we suppose $\phi \in J^{\rm ext}_{0,m-1}$ is non-zero and consider the linear functional $\lambda_\phi : S^{\rm skew}_{2,m} \to \mathbb{C}$. The Atkin–Lehner involution W_{p^∞} (cf. [45, §4.4]) acts on $S^{\rm skew}_{2,m}$ in such a way that

$$(W_{p^\infty}\varphi)(\tau, z) = \sum_{r \bmod 2m} \overline{g_{r^*}(\tau)}\theta^{(m)}_r(\tau, z) \tag{2.46}$$

when $\varphi = \sum_{r \bmod 2m} \overline{g_r}\theta^{(m)}_r$ is the theta-decomposition of $\varphi \in S^{\rm skew}_{2,m}$ and where the map $r \mapsto r^*$ is defined so that r^* is the unique solution (mod $2m$) to $r^* \equiv -r \pmod{2p^\nu}$ and $r^* \equiv r \pmod{2d}$.

By the definition of λ_ϕ we have $\lambda_\phi(\varphi) = \{\varphi, \psi^F\} = \overline{\chi}\sum_r\langle g_r, S^{(m)}_r\rangle$ with φ as above since the shadow of ψ^F is $\chi\sigma^{(m)} = \chi\sum_r \overline{S^{(m)}_r}\theta^{(m)}_r$. Taking $\varphi = W_{p^\infty}\sigma^{(m)}$ we see that $\lambda_\phi(W_{p^\infty}\sigma^{(m)}) = \overline{\chi}\sum_r\langle S^{(m)}_{r^*}, S^{(m)}_r\rangle$ is not zero according to the computation

$$\langle S^{(m)}_{r^*}, S^{(m)}_r\rangle = \frac{1}{2^6\pi m^{3/2}}\left(\delta_{r^*,r \pmod{2m}} - \delta_{r^*,-r \pmod{2m}}\right) \tag{2.47}$$

which can be obtained using the Rankin–Selberg formula. (Cf., e.g., (3.15) of [45]. A very similar computation is carried out in Proposition 10.2 of [45].) On the other hand for $\varphi = W_{p^\infty}\sigma^{(m)}$ we have $C_\varphi(1, 1) = 0$ since $r^* \not\equiv \pm1 \pmod{2m}$ for $r \equiv \pm1 \pmod{2m}$, and $S^{(m)}_r = O(q^{2/4m})$ for $r \not\equiv \pm1 \pmod{2m}$. So $\lambda_\phi(W_{p^\infty}\sigma^{(m)}) = 0$ in light of (2.45). This contradiction proves the claim. ☐

Proposition 2.8. *If m is a prime power $m = p^\nu$ and $\nu > 2$ then $J^{\rm ext}_{0,m-1} = \{0\}$.*

Proof. The proof is very similar to that of Proposition 2.7, computing $\lambda_\phi(\varphi)$ two ways using (2.44) and (2.45), but taking now $\varphi(\tau,z) = \sigma^{(p)}(\tau,p^\mu z)$ or $\varphi(\tau,z) = \sigma^{(p^2)}(\tau,p^\mu z)$ according as $\nu = 2\mu+1$ or $\nu = 2\mu+2$ with $\mu > 0$. The transformation $\varphi(\tau,z) \mapsto \varphi(\tau,tz)$ maps Jacobi forms of index m to Jacobi forms of index t^2m, and is one of the Hecke-like operators of [45, §4.4]. We leave the remaining details—the expression of φ in terms of $S^{(m)}_r$ and $\theta^{(m)}_r$, and an application of (2.47)—to the reader. ☐

We require one more result in advance of the proof of Theorem 2.2.

Lemma 2.9. *If $m = p^2$ for some prime p and there exists a newform $f \in S_2(p)$ with $L(f,1) \neq 0$ then $J^{\rm ext}_{0,m-1} = \{0\}$.*

Proof. Let m, p and $f \in S_2(p)$ be as in the statement of the lemma. Then, as in the proof of Theorem 2.6, there exists a uniquely determined $\varphi_f \in P^{\rm skew}_{2,p}$ with the same Hecke eigenvalues as f according to the results of [68, 69], and since $L(f,1) \neq 0$ we have $C_{\varphi_f}(1,1) \neq 0$. Now set $\varphi'_f = \varphi_f|V_p$ where V_p is the Hecke-like operator (cf. [45, (4.37)]) that maps Jacobi forms of index m to forms of index pm, and whose action is given explicitly by

$$C_{\varphi|V_p}(\Delta,r) = \sum_{d|\left(\frac{\Delta-r^2}{4p^2},r,p\right)} dC_\varphi\left(\frac{\Delta}{d^2},\frac{r}{d}\right) \tag{2.48}$$

in our special case that $\varphi = \varphi_f \in J^{\rm skew}_{2,p}$ when $\varphi = \sum C_\varphi(\Delta,r)\bar{q}^{\Delta/4p}q^{r^2/4p}y^r$ is the Fourier expansion of φ.

To prove that $J^{\rm ext}_{0,m-1} = \{0\}$ suppose that ϕ is a non-zero extremal form of index $m-1 = p^2-1$ and consider the functional $\lambda_\phi : S^{\rm skew}_{2,p^2} \to \mathbb{C}$ constructed in the proof of Theorem 2.6. Since $C_{\varphi_f}(1,1) \neq 0$ we have $C_{\varphi'_f}(1,1) \neq 0$ according to (2.48). So $\lambda_\phi(\varphi'_f) \neq 0$ thanks to (2.45) and Lemma 2.4. On the other hand the Hecke-like operator V_p commutes with all Hecke operators $T(n)$ (with, in our case, $(n,p)=1$) and so restricts to a map $P^{\rm skew}_{2,p} \to P^{\rm skew}_{2,p^2}$. Thus φ'_f is a Hecke-eigenform in $P^{\rm skew}_{2,p^2}$ and we have $\lambda_\phi(\varphi'_f) = 0$ by virtue of (2.44) and the fact that $P^{\rm skew}_{2,p^2}$ is orthogonal to the cusp form $\sigma^{(p^2)}$ of the trivial type. This contradiction completes the proof. ☐

Proof of Theorem 2.2. We have that $\dim J^{\rm ext}_{0,m-1} \leq 1$ for all m according to Proposition 2.5, and $\dim J^{\rm ext}_{0,m-1} = 0$ unless $m = p$ or $m = p^2$ for some prime p by virtue of Propositions 2.7 and 2.8. Applying Theorem 1 of [42] with $\sigma = 13/25\pi$, for example, shows that some $f \in S^{\rm new}_2(p)$ satisfies $L(f,1) \neq 0$ whenever p is a prime greater than or equal to 3001. The tables of arithmetic data on newforms posted at [71] give the non-vanishing or otherwise for every newform of level up to 5134, and inspecting the entries for the 430 prime levels less than 3000 we see that $S_2(p)$ has a newform f with $L(f,1)\neq 0$ for every prime p so long as $S_2(p)$ has a newform. We have $S_2^{\rm new}(p) = S_2(p) = \{0\}$ just when $p\in\{2,3,5,7,13\}$, so we conclude from Theorem 2.6 that $J^{\rm ext}_{0,m-1}=\{0\}$ for every prime $m=p$ such that $p-1$ does not divide 12. Also, we conclude from Lemma 2.9 that $J^{\rm ext}_{0,m-1}=\{0\}$ whenever $m=p^2$ is the square of a prime and $p-1$ does not divide 12. We inspect the tables of [71] again to find newforms with non-vanishing critical central value at levels $7^2=49$ and $13^2=169$, and apply Theorem 2.6 to conclude $J^{\rm ext}_{0,48}=J^{\rm ext}_{0,168}=\{0\}$.

So we now require to determine the dimension of $J^{\rm ext}_{0,m-1}$ for $m\in\{2,3,4,5,7,9,13,25\}$, which are the primes and squares of primes m for which $S_2(m)=\{0\}$. For this we utilise the basis $\{\varphi_n^{(m)}\}$ for $J_{0,*}$ determined by Gritsenko [43], and discussed, briefly, after the statement of Theorem 2.2 above. In more detail, the ring $J_{0,*}$ is finitely generated, by $\varphi_1^{(2)}$, $\varphi_1^{(3)}$ and $\varphi_1^{(4)}$, where

$$\begin{aligned}\varphi_1^{(2)} &= 4\left(f_2^2+f_3^2+f_4^2\right),\\ \varphi_1^{(3)} &= 2\left(f_2^2f_3^2+f_3^2f_4^2+f_4^2f_2^2\right),\\ \varphi_1^{(4)} &= 4f_2^2f_3^2f_4^2,\end{aligned}\tag{2.49}$$

and $f_i(\tau,z)=\theta_i(\tau,z)/\theta_i(\tau,0)$ for $i\in\{2,3,4\}$ (cf. §A.2). If we work over $\mathbb{Z}$ then we must include $\varphi_1^{(5)}$

$$\varphi_1^{(5)}=\frac{1}{4}\left(\varphi_1^{(4)}\varphi_1^{(2)}-(\varphi_1^{(3)})^2\right)\tag{2.50}$$

as a generator also, so that $J^{\mathbb{Z}}_{0,*}=\mathbb{Z}[\varphi_1^{(2)},\varphi_1^{(3)},\varphi_1^{(4)},\varphi_1^{(5)}]$. Following [43] we define

$$\begin{aligned}\varphi_1^{(7)} &= \varphi_1^{(3)}\varphi_1^{(5)}-(\varphi_1^{(4)})^2,\\ \varphi_1^{(9)} &= \varphi_1^{(3)}\varphi_1^{(7)}-(\varphi_1^{(5)})^2,\\ \varphi_1^{(13)} &= \varphi_1^{(5)}\varphi_1^{(9)}-2(\varphi_1^{(7)})^2,\end{aligned}\tag{2.51}$$

and define $\varphi_1^{(m)}$ for the remaining positive integers m according to the following recursive procedure. For $(12,m-1)=1$ and $m>5$ we set

$$\varphi_1^{(m)}=(12,m-5)\varphi_1^{(m-4)}\varphi_1^{(5)}+(12,m-3)\varphi_1^{(m-2)}\varphi_1^{(3)}-2(12,m-4)\varphi_1^{(m-3)}\varphi_1^{(4)}.\tag{2.52}$$

For $(12,m-1)=2$ and $m>10$ we set

$$\varphi_1^{(m)}=\frac{1}{2}\big((12,m-5)\varphi_1^{(m-4)}\varphi_1^{(5)}+(12,m-3)\varphi_1^{(m-2)}\varphi_1^{(3)}-2(12,m-4)\varphi_1^{(m-3)}\varphi_1^{(4)}\big).\tag{2.53}$$

For $(12, m-1) = 3$ and $m > 9$ we set

$$\varphi_1^{(m)} = \frac{2}{3}(12, m-4)\varphi_1^{(m-3)}\varphi_1^{(4)} + \frac{1}{3}(12, m-7)\varphi_1^{(m-6)}\varphi_1^{(7)} - (12, m-5)\varphi_1^{(m-4)}\varphi_1^{(5)}. \tag{2.54}$$

For $(12, m-1) = 4$ and $m > 16$ we set

$$\varphi_1^{(m)} = \frac{1}{4}\big((12, m-13)\varphi_1^{(m-12)}\varphi_1^{(13)} + (12, m-5)\varphi_1^{(m-4)}\varphi_1^{(5)} - (12, m-9)\varphi_1^{(m-8)}\varphi_1^{(9)}\big). \tag{2.55}$$

For $(12, m-1) = 6$ and $m > 18$ we set

$$\varphi_1^{(m)} = \frac{1}{3}(12, m-4)\varphi_1^{(m-3)}\varphi_1^{(4)} + \frac{1}{6}(12, m-7)\varphi_1^{(m-6)}\varphi_1^{(7)} - \frac{1}{2}(12, m-5)\varphi_1^{(m-4)}\varphi_1^{(5)}. \tag{2.56}$$

Finally, for $(12, m-1) = 12$ and $m > 24$ we set[1]

$$\varphi_1^{(m)} = \frac{1}{6}(12, m-4)\varphi_1^{(m-3)}\varphi_1^{(4)} - \frac{1}{4}(12, m-5)\varphi_1^{(m-4)}\varphi_1^{(5)} + \frac{1}{12}(12, m-7)\varphi_1^{(m-6)}\varphi_1^{(7)}. \tag{2.57}$$

The $\varphi_2^{(m)}$ are defined by setting

$$\begin{aligned}
\varphi_2^{(3)} &= (\varphi_1^{(2)})^2 - 24\,\varphi_1^{(3)},\\
\varphi_2^{(4)} &= \varphi_1^{(2)}\varphi_1^{(3)} - 18\,\varphi_1^{(4)},\\
\varphi_2^{(5)} &= \varphi_1^{(2)}\varphi_1^{(4)} - 16\,\varphi_1^{(5)},
\end{aligned} \tag{2.58}$$

and

$$\varphi_2^{(m)} = (12, m-4)\,\varphi_1^{(m-3)}\varphi_1^{(4)} - (12, m-5)\varphi_1^{(m-4)}\varphi_1^{(5)} - (12, m-1)\varphi_1^{(m)} \tag{2.59}$$

for $m > 5$, and the remaining $\varphi_n^{(m)}$ for $2 \leq m \leq 25$ are given by

$$\begin{aligned}
\varphi_n^{(m)} &= \varphi_{n-1}^{(m-3)}\varphi_1^{(4)},\\
\varphi_{m-2}^{(m)} &= (\varphi_1^{(2)})^{m-3}\varphi_1^{(3)},\\
\varphi_{m-1}^{(m)} &= (\varphi_1^{(2)})^{m-1},
\end{aligned} \tag{2.60}$$

where the first equation of (2.60) holds for $3 \leq n \leq m-3$.

Next we calculate that $\varphi_1^{(m)}$ defines a non-zero element of $J_{0,m-1}^{\rm ext}$ when $m-1$ divides 12, so $\dim J_{0,m-1}^{\rm ext} = 1$ for $m \in \{2, 3, 4, 5, 7, 13\}$, and it remains to show that $J_{0,m-1}^{\rm ext} = \{0\}$ for $m \in \{9, 25\}$. To do this we first observe that a weight zero form with vanishing Fourier coefficients of q^0y^k for $|k|>1$ necessarily has the form

---

[1] Our expression gives one possible correction for a small error in the last line on p. 10 of [43].

$$c_{0,1}\,\varphi_1^{(m)}+\sum_{i=1}^{\lfloor\frac{m-1}{6}\rfloor}\sum_{j=1}^{m-6i-1}c_{i,j}\,\zeta^i\varphi_j^{(m-6i)} \tag{2.61}$$

for some $c_{i,j}\in\mathbb{C}$. One has to show that the only such linear combination satisfying the extremal condition (2.37) necessarily has $c_{i,j}=0$ for all i,j (including $(i,j)=(0,1)$). An explicit inspection of the coefficients of terms q^ny^r with $r^2-4mn\geq 0$ for $n=1,2,3,4$ is sufficient to establish that $\dim J^{\rm ext}_{0,m-1}=0$ when $m=9$. For $m=25$ we notice that there are at least as many possible polar terms in the above sum as the number of parameters $c_{i,j}$. Indeed, by explicitly solving the system of linear equations we find that there is no accidental cancellation and the only solution to (2.61) that also satisfies the extremal condition (2.37) is zero. In this way we conclude that there is no solution to (2.37) in $J_{0,m-1}$ for $m\in\{9,25\}$. This completes the proof of the Theorem. □

The quantity $Z^{(2)}(\tau,z)=2\varphi_1^{(2)}(\tau,z)$ is equal to the elliptic genus of a(ny) $K3$ surface and the factor of two relating $Z^{(2)}$ to $\varphi_1^{(2)}$ is required in the $K3/M_{24}$ connection in order for the mock modular form $H^{(2)}=(H_1^{(2)})$ derived from $Z^{(2)}$ to have coefficients compatible with an interpretation as dimensions of representations of M_{24} for which the corresponding McKay–Thompson series $H_g^{(2)}$ have integer Fourier coefficients. Inspired by this we define the *umbral Jacobi forms*

$$Z^{(\ell)}(\tau,z)=2\varphi_1^{(\ell)}(\tau,z) \tag{2.62}$$

for $\ell\in\Lambda=\{2,3,4,5,7,13\}$. We also set $\chi^{(\ell)}$ to be the constant $Z^{(\ell)}(\tau,0)$ and find that $\chi^{(\ell)}=24/(\ell-1)$ for all $\ell\in\Lambda$.

Remark 2.10. The identity $(m-1)\chi=12b$ for $\phi=a+b(y+y^{-1})+O(q)$ established in Lemma 2.4 shows that there is no such Jacobi form with $b=1$ and a an integer unless $m-1$ divides 12. In particular, there is no extremal Jacobi form $\phi\in J^{\rm ext}_{0,m-1}$ such that $a_{\frac{m-1}{4},\frac12}=1$ and $a_{\frac{m-1}{4},0}$ is an integer unless $m-1$ divides 12. Inspecting the $Z^{(\ell)}$ we conclude that the divisors of 12 are exactly the values of $m-1$ for which such a Jacobi form exists.

Following the discussion in §§2.3,2.4, each of the umbral Jacobi forms $Z^{(\ell)}$ leads to an $(\ell-1)$-vector-valued mock modular form $H^{(\ell)}=\left(H_r^{(\ell)}\right)$ through the decomposition of $Z^{(\ell)}$ into $N=4$ characters, or equivalently through the decomposition of $\psi^{(\ell)}=\Psi_{1,1}Z^{(\ell)}$ into its polar and finite parts and the theta-expansion of the finite part,

$$\psi^{(\ell),F}(\tau,z)=\sum_{r=1}^{\ell-1}H_r^{(\ell)}(\tau)\hat{\theta}_r^{(\ell)}(\tau,z). \tag{2.63}$$

As we have explained above, the extremal condition translates into a natural condition on the vector-valued mock modular forms $H^{(\ell)}$: The requirement that $Z^{(\ell)}$ takes the form (2.37) is equivalent to requiring that the only polar term in $H^{(\ell)}=\left(H_r^{(\ell)}\right)$ is $-2q^{-\frac{1}{4\ell}}$ in the component $H_1^{(\ell)}$ and all the other components $H_r^{(\ell)}$ for $r\neq 1$ vanish as $\tau\to i\infty$, so that

$$H_r^{(\ell)}(\tau)=-2\delta_{r,1}q^{-\frac{1}{4\ell}}+O(q^{\frac{1}{4\ell}}) \tag{2.64}$$

for $0<r<\ell$.

Some low order terms in the Fourier expansions of the component functions $H_r^{(\ell)}$ obtained from the extremal forms $Z^{(\ell)}$ for $\ell\in\{2,3,4\}$ are given as follows.

$$H_1^{(2)}(\tau)=2q^{-1/8}\left(-1+45q+231q^2+770q^3+2277q^4+5796q^5+\cdots\right) \tag{2.65}$$

$$\begin{aligned}H_1^{(3)}(\tau)&=2q^{-1/12}\left(-1+16q+55q^2+144q^3+330q^4+704q^5+\cdots\right)\\H_2^{(3)}(\tau)&=2q^{2/3}\left(10+44q+110q^2+280q^3+572q^4+1200q^5+\cdots\right)\end{aligned} \tag{2.66}$$

$$\begin{aligned}H_1^{(4)}(\tau)&=2q^{-1/16}\left(-1+7q+21q^2+43q^3+94q^4+168q^5+\cdots\right)\\H_2^{(4)}(\tau)&=2q^{3/4}\left(8+24q+56q^2+112q^3+216q^4+392q^5+\cdots\right)\\H_3^{(4)}(\tau)&=2q^{7/16}\left(3+14q+28q^2+69q^3+119q^4+239q^5+\cdots\right)\end{aligned} \tag{2.67}$$

As a prelude to the next section we note that the coefficients 16, 55 and 144 appearing in $H_1^{(3)}$ are dimensions of irreducible representations of the Mathieu group M_{12} and that $\chi^{(3)}=12$ is the dimension of the defining permutation representation of M_{12} just as $\chi^{(2)}=24$ is the dimension of the defining permutation representation of M_{24}. We further note that the low-lying coefficients appearing in $H_2^{(3)}$ are dimensions of faithful irreducible representations of a group $2.M_{12}$. Here the notation $2.G$ denotes a group with a $\mathbb{Z}/2\mathbb{Z}$ normal subgroup such that $2.G/(\mathbb{Z}/2\mathbb{Z})=G$. Note also that $2.M_{12}$ has a faithful (and irreducible) 12-dimensional signed permutation representation (cf. §3.2). The pattern that the coefficients of $H_r^{(\ell)}$ for r odd are dimensions of representations of a group $\bar{G}^{(\ell)}$ with a permutation representation of dimension $\chi^{(\ell)}$ and the coefficients of $H_r^{(\ell)}$ for r even are dimensions of faithful representations of a group $G^{(\ell)}=2.\bar{G}^{(\ell)}$ with a signed permutation representation of degree $\chi^{(\ell)}$ persists for all $\ell\in\Lambda$; detailed descriptions of the (unsigned) permutation and signed permutation representations of

$\bar{G}^{(\ell)}$ and $G^{(\ell)}$ are given in §3.3 and §3.4.

The leading terms in the q-expansions of the mock modular forms $H_1^{(\ell)}$ that correspond via the procedure described earlier to the Jacobi forms $Z^{(\ell)}$ for $\ell \in \{5, 7, 13\}$ are

$$\begin{aligned} H_1^{(5)}(\tau) &= 2q^{-1/20}\left(-1+4q+9q^2+20q^3+35q^4+60q^5+\cdots\right),\\ H_1^{(7)}(\tau) &= 2q^{-1/28}\left(-1+2q+3q^2+5q^3+10q^4+15q^5+21q^6+\cdots\right),\\ H_1^{(13)}(\tau) &= 2q^{-1/52}\left(-1+q+q^2+q^4+q^5+2q^6+3q^7+\cdots\right). \end{aligned} \tag{2.68}$$

To avoid clutter we refrain from describing low order terms in the q-expansions of $H_r^{(\ell)}$ for $\ell \in \{5, 7, 13\}$ and $r > 1$ here, but these can be read off from the 1A entries in Tables 27-29, 31-35, and 37-47.

We conclude this section with a comparison of our condition (2.37) with other notions of extremal in the literature. A notion of *extremal holomorphic conformal field theory* was given in [27] following earlier related work on vertex operator superalgebras in [72]. Extremal CFT's have central charge $c = 24k$ with k a positive integer and are defined in such a way that their partition function satisfies

$$Z = q^{-k}\prod_{n>1}^{\infty}\frac{1}{1-q^n} + O(q)\prod_{n>0}^{\infty}\frac{1}{1-q^n} \tag{2.69}$$

as $\tau \to i\infty$ where the term $O(q)$ is presumed to be a series in q with integer coefficients, so that the second term $O(q)\prod_{n>0}(1-q^n)^{-1}$ in (2.69) represents an integer combination of irreducible characters of the Virasoro algebra. The first term in (2.69) is the vacuum character of the Virasoro algebra, generated by the vacuum state, and thus any Virasoro primaries above the vacuum are only allowed to contribute positive powers of q to the partition function. At this time the only known example of an extremal CFT is that determined by the monster vertex operator algebra $V^\natural$ whose partition function has $k = 1$ in (2.69) so this notion is, at the very least, good at singling out extraordinary structure.

If ϕ is a weak Jacobi form of weight 0 and index $m-1$ that is extremal in our sense then we have

$$\phi = a_{\frac{m-1}{4},0}\mathrm{ch}^{(m)}_{\frac{m-1}{4},0} + a_{\frac{m-1}{4},\frac{1}{2}}\mathrm{ch}^{(m)}_{\frac{m-1}{4},\frac{1}{2}} + \sum_{0<r<m} O(q)\frac{\hat{\theta}_r^{(m)}}{\Psi_{1,1}} \tag{2.70}$$

as $\tau \to i\infty$ for some $a_{\frac{m-1}{4},0}$ and $a_{\frac{m-1}{4},\frac{1}{2}}$, and the third term in (2.70) is a natural counterpart to the second term in (2.69) since the massive $N = 4$ characters (in the Ramond sector with $(-1)^F$ insertion) are all of the form $q^\alpha\hat{\theta}_r^{(m)}/\Psi_{1,1}$ for some α and some r. It is harder to argue that the massless $N = 4$ contributions in (2.70) are in direct analogy with the first term in

(2.69) since the vacuum state in a superconformal field theory with $N = 4$ supersymmetry will generally (i.e. when the index is greater than 1) give rise to non-zero massless $N = 4$ character contributions with spin greater than 1/2. We remark that the stronger condition

$$\phi = a_{\frac{m-1}{4},0}\mathrm{ch}^{(m)}_{\frac{m-1}{4},0} + \sum_{0<r<m} O(q)\frac{\hat{\theta}^{(m)}_r}{\Psi_{1,1}} \tag{2.71}$$

has no solutions according to Lemma 2.4. According to Theorem 2.2 the six Jacobi forms $Z^{(\ell)}$ of umbral moonshine are the unique solutions to (2.70) having $a_{\frac{m-1}{4},\frac{1}{2}} = -2$.

A notion of *extremal conformal field theory with* $N = (2,2)$ *superconformal symmetry* was introduced in [73] and the Ramond sector partition function of such an object defines a weak Jacobi form of weight 0 and some index but will generally not coincide with a Jacobi form that is extremal in our sense since, as has been mentioned, our functions are free from contributions arising from states in the Ramond sector that are related by spectral flow to the vacuum state in the Neveu–Schwarz sector, except in the case of index 1.

Despite the absence of a notion of extremal conformal field theory underlying our extremal Jacobi forms it is interesting to reflect on the fact that the one known example of an extremal CFT is that (at $k = 1$) determined by the moonshine vertex operator algebra of [12] with partition function $Z(\tau) = J(\tau)$. This function encodes dimensions of irreducible representations of the monster and, as we have seen to some extent above and will see in more detail below, the quantities which play the same role with respect to the groups $G^{(\ell)}$ of umbral moonshine are precisely the mock modular forms $H^{(\ell)}(\tau) = \left(H^{(\ell)}_r(\tau)\right)$ which arise naturally from the extremal Jacobi forms $Z^{(\ell)}(\tau, z)$ according to the procedure of §2.3. One of the main motivations for the notion of extremal CFT introduced in [27] was a possible connection to pure (chiral) gravity theory in 3-dimensional Anti-de Sitter space via the AdS/CFT correspondence and it is interesting to compare this with the important rôle that Rademacher sum constructions play in monstrous moonshine [25], umbral moonshine at $\ell = 2$ [24], and in umbral moonshine more generally (cf. §1 and §5.2). We refer to [28, 29, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85] for further discussions on the AdS/CFT correspondence and extremal CFT's.

2.6 Siegel Modular Forms

Siegel modular forms are automorphic forms which generalise modular forms by replacing the modular group $SL_2(\mathbb{Z})$ by the *genus n Siegel modular group* $Sp_{2n}(\mathbb{Z})$ and the upper half-plane $\mathbb{H}$

by the *genus n Siegel upper half-plane* $\mathbb{H}_n$. Here we restrict ourselves to the case $n = 2$. Define

$$J = \begin{pmatrix} 0 & -I_2 \\ I_2 & 0 \end{pmatrix} \tag{2.72}$$

with I_2 the unit 2×2 matrix and let $Sp_4(\mathbb{Z})$ be the group of 4×4 matrices $\gamma \in M_4(\mathbb{Z})$ satisfying $\gamma J \gamma^t = J$. If we write γ in terms of 2×2 matrices with integer entries A, B, C, D,

$$\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \tag{2.73}$$

then the condition $\gamma J \gamma^t = J$ becomes

$$AB^t = BA^t, \qquad CD^t = DC^t, \qquad AD^t - BC^t = 1. \tag{2.74}$$

Just as $SL_2(\mathbb{Z})$ has a natural action on $\mathbb{H}$, the (genus 2) Siegel modular group $Sp_4(\mathbb{Z})$ has a natural action on the (genus 2) Siegel upper half-plane, $\mathbb{H}_2$, defined as the set of 2×2 complex, symmetric matrices

$$\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \tag{2.75}$$

obeying

$$\mathrm{Im}(\tau) > 0, \qquad \mathrm{Im}(\sigma) > 0, \qquad \det(\mathrm{Im}(\Omega)) > 0. \tag{2.76}$$

The action of $\gamma \in Sp_4(\mathbb{Z})$ is given by

$$\gamma\Omega = (A\Omega + B)(C\Omega + D)^{-1} \tag{2.77}$$

when γ is given by (2.73). A *Siegel modular form* of weight k for $\Gamma \subset Sp_4(\mathbb{Z})$ is a holomorphic function $F : \mathbb{H}_2 \to \mathbb{C}$ obeying the transformation law

$$F((A\Omega + B)(C\Omega + D)^{-1}) = \det(C\Omega + D)^k F(\Omega) \tag{2.78}$$

for $\gamma \in \Gamma$. We can write a *Fourier-Jacobi decomposition* of $F(\Omega)$ in terms of $p = e(\sigma)$ as

$$F(\Omega) = \sum_{m=0}^{\infty} \varphi_m(\tau, z) p^m \tag{2.79}$$

and the transformation law for $F(\Omega)$ can be used to show that the Fourier-Jacobi coefficient $\varphi_m(\tau,z)$ is a Jacobi form of weight k and index m. (This is one of the main motivations for the notion of Jacobi form; cf. [86] for an early analysis with applications to affine Lie algebras.) We can thus write

$$\varphi_m(\tau,z)=\sum_{\substack{n,r\in\mathbb{Z}\\ 4mn-r^2\geq 0}} c(m,n,r)q^ny^r \tag{2.80}$$

and then

$$F(\Omega)=\sum_{m,n,r} c(m,n,r)p^mq^ny^r. \tag{2.81}$$

A special class of Siegel modular forms, called *Spezialschar* by Maass, arise by taking the Jacobi-Fourier coefficients φ_m to be given by $\varphi_m=\varphi_1|V_m$ where $\varphi_1\in J_{k,1}$ and V_m is the *Hecke-like operator* defined so that if $\varphi_1=\sum_{n,r}c(n,r)q^ny^r$ then

$$\varphi_1|V_m=\sum_{n,r}\left(\sum_{j|(n,r,m)} j^{k-1}c\left(\frac{nm}{j^2},\frac{r}{j}\right)\right)q^ny^r. \tag{2.82}$$

It develops that the function

$$F(\Omega)=\sum_{m=0}^{\infty}(\varphi_1|V_m)(\tau,z)p^m \tag{2.83}$$

is a weight k Siegel modular form known as the *Saito–Kurokawa* or *additive lift* of the weight k and index 1 Jacobi form φ_1. An important example arises by taking the additive lift of the Jacobi form

$$\varphi_{10,1}(\tau,z)=-\eta(\tau)^{18}\theta_1(\tau,z)^2 \tag{2.84}$$

(cf. §A) which produces the *Igusa cusp form*

$$\Phi_{10}(\Omega)=\sum_{m=1}^{\infty}(\varphi_{10,1}|V_m)(\tau,z)p^m \tag{2.85}$$

The Igusa cusp form also admits a product representation obtained from the *Borcherds* or *exponential lift* of the umbral Jacobi form $Z^{(2)}=2\varphi_{2,1}$ (cf. (2.49)) which is

$$\Phi_{10}(\Omega)=pqy\prod_{\substack{m,n,r\in\mathbb{Z}\\ (m,n,r)>0}}(1-p^mq^ny^r)^{c^{(2)}(4mn-r^2)} \tag{2.86}$$

where the coefficients $c^{(2)}$ are defined by the Fourier expansion of $Z^{(2)}$

$$Z^{(2)}(\tau,z)=\sum_{n,r}c^{(2)}(4n-r^2)q^ny^r \tag{2.87}$$

and where the condition $(m,n,r)>0$ is that either $m>0$ or $m=0$ and $n>0$ or $m=n=0$ and $r<0$.

According to Theorem 2.1 in [87] the umbral Jacobi form $Z^{(\ell)}$ defines a Siegel modular form $\Phi^{(\ell)}$ on the *paramodular group* $\Gamma^+_{\ell-1}<Sp_4(\mathbb{Q})$ via the Borcherds lift for each $\ell\in\Lambda$. (We refer the reader to [87] for details.) For small values of ℓ these Siegel forms $\Phi^{(\ell)}$ have appeared in the literature (in particular in the work [88, 87] of Gritsenko–Nikulin). Taking $\ell\in\Lambda$ and defining $c^{(\ell)}(n,r)$ so that

$$Z^{(\ell)}(\tau,z)=\sum_{n,r}c^{(\ell)}(n,r)q^ny^r \tag{2.88}$$

we have the exponential lift $\Phi^{(\ell)}$ of weight $k=c^{(\ell)}(0,0)/2$ for $\Gamma^+_{\ell-1}$ given by

$$\Phi^{(\ell)}(\Omega)=p^{A(\ell)}q^{B(\ell)}y^{C(\ell)}\prod_{(m,n,r)>0}(1-p^mq^ny^r)^{c^{(\ell)}(mn,r)} \tag{2.89}$$

where

$$A(\ell)=\frac{1}{24}\sum_{r}c^{(\ell)}(0,r),\quad B(\ell)=\frac{1}{2}\sum_{r>0}rc^{(\ell)}(0,r),\quad C(\ell)=\frac{1}{4}\sum_{r}r^2c^{(\ell)}(0,r). \tag{2.90}$$

Note that for $\ell\in\{2,3,4,5\}$ we have $\Phi^{(\ell)}=(\Delta_k)^2$ in the notation of [87] where k is given by $k=(7-\ell)/(\ell-1)$. These four functions Δ_k appear as denominator functions for Lorentzian Kac–Moody Lie (super)algebras in [87, §5.1] (see also [89]) and in connection with mirror symmetry for $K3$ surfaces in [87, §5.2]. We refer the reader to §5.5 for more discussion on this.

3 Finite Groups

In this section we introduce the *umbral groups* $G^{(\ell)}$ for $\ell\in\Lambda=\{2,3,4,5,7,13\}$. It will develop that the representation theory of $G^{(\ell)}$ is intimately related to the vector-valued mock modular form $H^{(\ell)}$ of §2.5.

We specify the abstract isomorphism types of the groups explicitly in §3.1. Each group admits a quotient $\bar{G}^{(\ell)}$ which is naturally realised as a permutation group on $24/(\ell-1)$ points. We construct these permutations explicitly in §3.3. In order to construct the $G^{(\ell)}$ we use signed permutations—a notion we discuss in §3.2—and explicit generators for the $G^{(\ell)}$ are finally obtained in §3.4. The signed permutation constructions are then used (again in §3.4) to define characters for $G^{(\ell)}$—the *twisted Euler characters*—which turn out to encode the automorphy of the mock modular forms $H_g^{(\ell)}$ that are be described in detail in §4. In §§3.5-3.6 we describe curious connections between the $G^{(\ell)}$ and certain Dynkin diagrams.

3.1 Specification

For $\ell \in \Lambda$ let abstract groups $G^{(\ell)}$ and $\bar{G}^{(\ell)}$ be as specified in Table 1. We will now explain the notation used therein (moving from right to left).

We write n as a shorthand for $\mathbb{Z}/n\mathbb{Z}$ (in the second and third rows of Table 1) and Sym_n denotes the symmetric group on n points. We write Alt_n for the alternating group on n points, which is the subgroup of Sym_n consisting of all even permutations.

We say that G is a *double cover* of a group H and write $G \simeq 2.H$ (cf. [90, §5.2]) in case G has a subgroup Z of order 2 that is normal (and therefore central, being of order two) with the property that G/Z is isomorphic to H. We say that G is a *non-trivial* double cover of H if it is a double cover that is not isomorphic to the direct product $2 \times H$. (We don't usually write $G \simeq 2.H$ unless G is a non-trivial cover of H.) The cyclic group of order 4 is a non-trivial double cover of the group of order 2.

For n a positive integer and q a prime power we write $GL_n(q)$ for the general linear group of invertible $n \times n$ matrices with coefficients in the finite field $\mathbb{F}_q$ with q elements, and we write $SL_n(q)$ for the subgroup consisting of matrices with determinant 1. We write $PGL_n(q)$ for the quotient of $GL_n(q)$ by its centre but we adopt the ATLAS convention (cf. [90, §2.1]) of writing $L_n(q)$ as a shorthand for $PSL_n(q)$—being the quotient of $SL_n(q)$ by its centre—since this group is typically simple. In the case that $q = 3$ and n is even the centre of $SL_n(q)$ has order 2 and $SL_n(q) \simeq 2.L_n(q)$ is a non-trivial double cover of $L_n(q)$.

In case $q = 5$ the centre of $GL_n(q)$ is a cyclic group of order 4 and so $GL_n(5)$ has a unique central subgroup of order 2. We write $GL_n(5)/2$ for the quotient of $GL_n(5)$ by this subgroup. In case $n = 2$ the exceptional isomorphism $PGL_2(5) \simeq Sym_5$ tells us then that $GL_2(5)/2$ is a double cover of the symmetric group Sym_5. For $n \geq 4$ there are two isomorphism classes of non-trivial double covers of Sym_n with the property that the central subgroup of order 2 is contained in the commutator subgroup of the double cover—these are the so-called *Schur double covers* (cf. [90, §4.1, §6.7]). The group $GL_2(5)/2$ is curious in that its only subgroup of index 2 is a direct product $2 \times Alt_5$ and its commutator subgroup is a copy of Alt_5, so it is a non-trivial double cover of Sym_5 that is not isomorphic to either of the Schur double covers.

The symbols $AGL_n(q)$ denote the *affine linear group* generated by the natural action of

Table 1: The Umbral Groups

ℓ	2	3	4	5	7	13
$G^{(\ell)}$	M_{24}	$2.M_{12}$	$2.AGL_3(2)$	$GL_2(5)/2$	$SL_2(3)$	4
$\bar{G}^{(\ell)}$	M_{24}	M_{12}	$AGL_3(2)$	$PGL_2(5)$	$L_2(3)$	2

$GL_n(q)$ on $\mathbb{F}_q^n$ and the translations $x \mapsto x + v$ for $v \in \mathbb{F}_q^n$. The group $AGL_n(q)$ may be realised as a subgroup of $GL_{n+1}(q)$ so in particular $AGL_3(2)$ embeds in $GL_4(2)$. The group $GL_4(2)$ is unusual amongst the $GL_n(2)$ in that it admits a non-trivial double cover $2.GL_4(2)$, which is a manifestation of the exceptional isomorphism $GL_4(2) \simeq Alt_8$. There are two conjugacy classes of subgroups of $2.Alt_8$ of order 2688, which is twice the order of $AGL_3(2)$. The groups in both classes are isomorphic to a particular non-trivial double cover of $AGL_3(2)$ and this is the group we denote $2.AGL_3(2)$ in Table 1.

The symbols M_{24} and M_{12} denote the sporadic simple Mathieu groups attached to the binary and ternary Golay codes, respectively. The group M_{24} is the automorphism group of the binary Golay code, which is the unique self-dual linear binary code of length 24 with minimum weight 8 (cf. [91]). The ternary Golay code is the unique self-dual linear ternary code of length 12 with minimum weight 6 (cf. [91]) and its automorphism group is a non-trivial double cover of M_{12}. There is a unique such group up to isomorphism (cf. [90]) which we denote by $2.M_{12}$ in Table 1.

Observe that for $\ell > 2$ the group $G^{(\ell)}$ has a unique central subgroup of order 2. Then $\bar{G}^{(\ell)}$ may be described for $\ell > 2$ by $\bar{G}^{(\ell)} = G^{(\ell)}/2$ and $G^{(\ell)}$ is a non-trivial double cover of $\bar{G}^{(\ell)}$ for each $\ell > 2$. It will develop in §3.2 that $\bar{G}^{(\ell)}$ is a permutation group of degree $n = 24/(\ell - 1)$ for each $\ell \in \Lambda$. Since $G^{(2)} \simeq M_{24}$ has trivial centre and is already a permutation group of degree $24 = 24/(2 - 1)$ we set $\bar{G}^{(2)} = G^{(2)}$.

Generalising the notation used above for double covers we write $G \simeq N.H$ to indicate that G fits into a short exact sequence

$$1 \to N \to G \to H \to 1 \tag{3.1}$$

for some groups N and H. We write $G \simeq N{:}H$ for a group of the form $N.H$ for which the sequence (3.1) splits (i.e. in case G is a semi-direct product $N \rtimes H$). Then we have $AGL_3(2) \simeq 2^3{:}L_2(7)$ according to the exceptional isomorphism $L_3(2) \simeq L_2(7)$ where 2^3 denotes an elementary abelian group of order 8.

3.2 Signed Permutations

The group of *signed permutations of degree* n or *hyperoctahedral group of degree* n, denoted here by Oct_n, is a semi-direct product $2^n{:}Sym_n$ where 2^n denotes an elementary abelian group of order 2^n. We may realise it explicitly as the subgroup of invertible linear transformations of an n-dimensional vector space generated by sign changes and permutations in a chosen basis. (This recovers $2^n{:}Sym_n$ so long as the vector space is defined over a field of characteristic other than 2. In case the characteristic is 2 the sign changes are trivial and we recover Sym_n.) When we write Oct_n we usually have in mind the data of fixed subgroups $N \simeq 2^n$ and $H \simeq Sym_n$ such that N is normal and $Oct_n/N \simeq H$, such as are given by sign changes and coordinate permutations, respectively, when we realise Oct_n explicitly as described above. In what follows we assume such data to be chosen for each n and write $Oct_n \to Sym_n$ for the composition $Oct_n \to Oct_n/N \simeq Sym_n$.

We will show in §3.4 that each $G^{(\ell)}$ for $\ell \in \Lambda$ admits a realisation as a subgroup of Oct_n for $n = 24/(\ell-1)$ such that the image of $G^{(\ell)}$ under the map $Oct_n \to Sym_n$ is $\bar{G}^{(\ell)}$.

In §3.4 we use the following modification of the usual cycle notation for permutations to denote elements of Oct_n. Suppose Ω is a set with n elements and V is the vector space generated over a field $\mathbf{k}$ by the symbols $\{e_x\}_{x\in\Omega}$. Whereas the juxtaposition xy occurring in a cycle $(...xy...)$ indicates a coordinate permutation mapping e_x to e_y, we write $x\bar{y}$ to indicate that a sign change is applied so that e_x is mapped to $-e_y$. Then, for example, if $\Omega = \{\infty, 0, 1, 2, 3, 4\}$ we write $\sigma = (\bar{\infty}2\bar{3}4)(\bar{0})$ for the element of $GL(V)$ determined by

$$\sigma : e_\infty \mapsto e_2, \quad e_2 \mapsto -e_3, \quad e_3 \mapsto e_4, \quad e_4 \mapsto -e_\infty, \quad e_0 \mapsto -e_0. \tag{3.2}$$

(We think of the bar over the 3 in $(...2\bar{3}4...)$ as "occurring between" the 2 and 3.) We call the symbol 1 a *fixed point* of σ and we call 0 an *anti-fixed point*.

We define the *signed permutation character* of Oct_n by setting

$$\begin{aligned} \chi : Oct_n &\to \mathbb{Z} \\ g &\mapsto \chi_g = h_{g,+} - h_{g,-} \end{aligned} \tag{3.3}$$

where $h_{g,+}$ is the number of fixed points of g and $h_{g,-}$ is the number of anti-fixed points. Then χ is just the character of the ordinary representation of Oct_n furnished by V that obtains when the field $\mathbf{k}$ is taken to be $\mathbb{C}$. Writing $\bar{\chi}$ for the composition of $Oct_n \to Sym_n$ with the usual permutation character of Sym_n we have

$$\begin{aligned} \bar{\chi} : Oct_n &\to \mathbb{Z} \\ g &\mapsto \bar{\chi}_g = h_{g,+} + h_{g,-} \end{aligned} \tag{3.4}$$

and we call $\bar{\chi}$ the *unsigned permutation character* of Oct_n. Then the signed and unsigned permutation characters χ and $\bar{\chi}$ together encode the number of fixed and anti-fixed points for each $g \in Oct_n$.

Let us take $\mathbf{k} = \mathbb{C}$ in the realisation of Oct_n as a subgroup of $GL(V)$. Then to each element $g \in Oct_n$ we assign a *signed permutation Frame shape* Π_g which encodes the eigenvalues of the corresponding (necessarily diagonalisable) linear transformation of V in the following way. An expression

$$\Pi_g = \prod_{k \geq 1} k^{m_g(k)} \tag{3.5}$$

with $m_g(k) \in \mathbb{Z}$ and $m_g(k) = 0$ for all but finitely many k indicates that g defines a linear transformation with $m_g(k)$ eigenvalues equal to $\mathrm{e}(j/k)$ for each $0 \leq j < k$ in the case that all the $m_g(k)$ are non-negative. If some $m_g(k)$ are negative then we find the number of eigenvalues equal to ξ say by looking at how many copies of ξ are present in $\Pi_g^+ = \prod_{k \geq 1,\, m_g(k) > 0} k^{m_g(k)}$ and subtracting the number of copies indicated by $\Pi_g^- = \prod_{k \geq 1,\, m_g(k) < 0} k^{-m_g(k)}$. Observe that the signed permutation character of Oct_n is recovered from the signed permutation Frame shapes via $\chi_g = m_g(1)$. Also, the Frame shape is invariant under conjugacy.

The map $Oct_n \to Sym_n$ (which may be realised by "ignoring" sign changes) furnishes a (non-faithful) permutation representation of Oct_n on n points; we call it the *unsigned permutation representation* of Oct_n. We write $g \mapsto \bar{\Pi}_g$ for the corresponding cycle shapes and call them the *unsigned permutation Frame shapes* attached to Oct_n. Observe that the unsigned permutation character of Oct_n is recovered from the unsigned permutation Frame shapes via $\bar{\chi}_g = \bar{m}_g(1)$ when $\bar{\Pi}_g = \prod_{k \geq 1} k^{\bar{m}_g(k)}$.

Observe that we obtain a faithful permutation representation $Oct_n \to Sym_{2n}$ by regarding $g \in Oct_n$ as a permutation of the $2n$ points $\{\pm e_x\}_{x \in \Omega}$. We denote the corresponding cycle shapes $\tilde{\Pi}_g$ and call them the *total permutation Frame shapes* attached to Oct_n. Then the total permutation Frame shapes can be recovered from the signed and unsigned permutation Frame shapes for if we define a formal product on Frame shapes by setting

$$\Pi\,\Pi' = \prod_{k\geq 1} k^{m(k)+m'(k)}. \tag{3.6}$$

in case $\Pi = \prod_{k\geq 1} k^{m(k)}$ and $\Pi' = \prod_{k\geq 1} k^{m'(k)}$ then we have $\tilde{\Pi}_g = \Pi_g \bar{\Pi}_g$ for all $g \in Oct_n$.

Suppose that G is a subgroup of Oct_n with the property that the intersection $G \cap N$ has order 2. (This will be the case for $G = G^{(\ell)}$ when $\ell \in \Lambda$ and $\ell \neq 2$.) Let z be the unique and necessarily central involution in $G \cap N$ and write $\bar{G}$ for the image of G under the map $Oct_n \to Sym_n$. Then the conjugacy class of zg depends only on the conjugacy class of g and we obtain an involutory map $[g] \mapsto [zg]$ on the conjugacy classes of G. We call $[g]$ and $[zg]$ *paired* conjugacy classes and we say that $[g]$ is *self-paired* if $[g] = [zg]$. Observe that z must act as -1 times the identity in any faithful irreducible representation of G so if $g \mapsto \chi(g)$ is the character of such a representation then $\chi(zg) = -\chi(g)$. In particular, $\chi(g) = 0$ if g is self-paired.

3.3 Realisation Part I

In this section we construct the groups $\bar{G}^{(\ell)}$ as subgroups of Sym_n where $n = 24/(\ell-1)$. This construction will be nested in the sense that each group $\bar{G}^{(\ell)}$ will be realised as a subgroup of some $\bar{G}^{(\ell')}$ for $\ell'-1$ a divisor of $\ell-1$.

For $\ell = 2$ let $\Omega^{(2)}$ be a set with 24 elements and let $\mathcal{G} \subset \mathcal{P}(\Omega^{(2)})$ be a copy of the Golay code on $\Omega^{(2)}$. Then the subgroup of the symmetric group $Sym_{\Omega^{(2)}}$ of permutations of the set $\Omega^{(2)}$ that preserves $\mathcal{G}$ is isomorphic to M_{24}. So we may set

$$\bar{G}^{(2)} = \left\{\sigma \in Sym_{\Omega^{(2)}} \mid \sigma(C) \in \mathcal{G}, \forall C \in \mathcal{G}\right\}.$$

For $\ell = 3$ the largest proper divisor of $\ell - 1 = 2$ is $1 = 2-1$. Choose a partition of $\Omega^{(2)}$ into $2/1 = 2$ subsets of $24/2 = 12$ elements such that each 12-element set belongs to $\mathcal{G}$ and denote it $P^{(3)} = \{\Omega^{(3)}, \Omega^{(3)'}\}$. Equivalently, take $\Omega^{(3)}$ to be the symmetric difference of the sets of fixed-points of elements $\sigma, \sigma' \in \bar{G}^{(2)}$ of cycle shape $1^8 2^8$ such that $\sigma\sigma'$ has order 6. (That is, $\Omega^{(3)}$ consists of the points that are fixed by σ or σ' but not both. In turns out that if the product $\sigma\sigma'$ has order 6 then its cycle shape is $1^2 2^2 3^2 6^2$ and so the fixed-point sets of σ and σ' have intersection of size 2 and $\Omega^{(3)}$ and $\Omega^{(3)'} = \Omega^{(2)} \setminus \Omega^{(3)}$ both have 12 elements.) Then the group of permutations of $\Omega^{(3)}$ induced by the subgroup of $\bar{G}^{(2)}$ that fixes this partition is a copy of $\bar{G}^{(3)} \simeq M_{12}$. Explicitly, and to explain what we mean here by fix, if $\bar{G}^{(2)}_{P^{(3)}}$ denotes the subgroup of $\bar{G}^{(2)}$ that fixes the partition $P^{(3)}$ in the sense that

$$\bar{G}^{(2)}_{P^{(3)}} = \left\{ \sigma \in \bar{G}^{(2)} \mid \sigma(C) = C,\, \forall C \in P^{(3)} \right\}, \tag{3.7}$$

and if $\varrho : \bar{G}^{(2)}_{P^{(3)}} \to Sym_{\Omega^{(3)}}$ denotes the natural map obtained by restricting elements of $\bar{G}^{(2)}_{P^{(3)}}$ to $\Omega^{(3)}$,

$$\begin{aligned} \varrho : \bar{G}^{(2)}_{P^{(3)}} &\to Sym_{\Omega^{(3)}} \\ \sigma &\mapsto \sigma|_{\Omega^{(3)}}, \end{aligned} \tag{3.8}$$

then $\bar{G}^{(3)}$ is the image of ϱ. The kernel of this map is the subgroup

$$\bar{G}^{(2)}_{P^{(3)},\Omega^{(3)}} = \left\{ \sigma \in \bar{G}^{(2)}_{P^{(3)}} \mid \sigma(x) = x,\, \forall x \in \Omega^{(3)} \right\} \tag{3.9}$$

comprised of permutations in $\bar{G}^{(2)}_{P^{(3)}}$ that fix every element of $\Omega^{(3)}$ so we have

$$\bar{G}^{(3)} = \varrho\left(\bar{G}^{(2)}_{P^{(3)}}\right) \simeq \bar{G}^{(2)}_{P^{(3)}} / \bar{G}^{(2)}_{P^{(3)},\Omega^{(3)}} \simeq M_{12}.$$

For $\ell = 4$ the largest proper divisor of $\ell - 1 = 3$ is $1 = 2 - 1$. Choose a partition of $\Omega^{(2)}$ into $3/1 = 3$ subsets of $24/3 = 8$ elements that belong to $\mathcal{G}$ and denote it $P^{(4)} = \{\Omega^{(4)}, \Omega^{(4)'}, \Omega^{(4)''}\}$. Equivalently, choose $\Omega^{(4)}$ and $\Omega^{(4)'}$ to be the fixed-point sets of respective elements σ and σ' of order 2 in $\bar{G}^{(2)}$ having cycle shapes $1^8 2^8$ and disjoint fixed-point sets and the property that $\sigma\sigma'$ has order 3. Then the group of permutations of $\Omega^{(4)}$ induced by the subgroup of $\bar{G}^{(2)}$ that fixes this partition is a copy of the group $\bar{G}^{(4)} \simeq AGL_3(2)$ and we have

$$\bar{G}^{(4)} = \varrho\left(\bar{G}^{(2)}_{P^{(4)}}\right) \simeq \bar{G}^{(2)}_{P^{(4)}} / \bar{G}^{(2)}_{P^{(4)},\Omega^{(4)}} \simeq AGL_3(2)$$

where $\bar{G}^{(2)}_{P^{(4)}}$, the map ϱ and the subgroup $\bar{G}^{(2)}_{P^{(4)},\Omega^{(4)}}$ are defined according to the natural analogues of (3.7), (3.8) and (3.9), respectively.

For $\ell = 5$ the largest proper divisor of $\ell - 1 = 4$ is $2 = 3 - 1$. Choose a partition $P^{(5)} = \{\Omega^{(5)}, \Omega^{(5)'}\}$ of $\Omega^{(3)}$ into $4/2 = 2$ subsets of $12/2 = 6$ elements such that neither of the sets in $P^{(5)}$ is contained in a set of size 8 in $\mathcal{G}$. Equivalently, take $\Omega^{(5)}$ to be the symmetric difference of the sets of fixed-points of elements $\sigma, \sigma' \in \bar{G}^{(3)}$ of cycle shape $1^4 2^4$ such that $\sigma\sigma'$ has order 6. (This condition forces the fixed-point sets of σ and σ' to have a single point of intersection so that $\Omega^{(5)}$ and $\Omega^{(5)'} = \Omega^{(3)} \setminus \Omega^{(5)}$ both have 6 elements.) Then the group of permutations of

$\Omega^{(5)}$ induced by the subgroup of $\bar{G}^{(3)}$ that fixes this partition is a copy of $\bar{G}^{(5)} \simeq PGL_2(5)$.

$$\bar{G}^{(5)} = \varrho\left(\bar{G}^{(3)}_{P^{(5)}}\right) \simeq \bar{G}^{(3)}_{P^{(5)}}/\bar{G}^{(3)}_{P^{(5)},\Omega^{(5)}} \simeq PGL_2(5)$$

For $\ell = 7$ the largest proper divisor of $\ell - 1 = 6$ is $3 = 4 - 1$. Choose a partition $P^{(7)} = \{\Omega^{(7)}, \Omega^{(7)'}\}$ of $\Omega^{(4)}$ into $6/3 = 2$ subsets of $8/2 = 4$ elements such that $\Omega^{(7)}$ (and therefore also $\Omega^{(7)'} = \Omega^{(4)} \setminus \Omega^{(7)}$) is the set of fixed points of an element of order 2 in $\bar{G}^{(4)}$ having cycle shape $1^4 2^2$. (There are three conjugacy classes of elements of order 2 in $\bar{G}^{(4)}$ but for just one of these classes do the elements have the cycle shape $1^4 2^2$.) Then the group of even permutations of $\Omega^{(7)}$ induced by the subgroup of $\bar{G}^{(4)}$ that fixes this partition is a copy of the group $\bar{G}^{(7)} \simeq L_2(3)$, which is of course isomorphic to the alternating group on 4 points.

$$\bar{G}^{(7)} = \varrho\left(\bar{G}^{(4)}_{P^{(7)}}\right) \cap Alt_{\Omega^{(7)}} \simeq L_2(3)$$

(The quotient $\bar{G}^{(4)}_{P^{(7)}}/\bar{G}^{(4)}_{P^{(7)},\Omega^{(7)}}$ is isomorphic to the full symmetric group on 4 points so the restriction to even permutations is not redundant.)

The next largest divisor of $7 - 1 = 6$ is $2 = 3 - 1$. An alternative construction of $\bar{G}^{(7)}$ is obtained by choosing a partition $P^{(7)} = \{\Omega^{(7)}, \Omega^{(7)'}, \Omega^{(7)''}\}$ of $\Omega^{(3)}$ into $6/2 = 3$ subsets of $12/3 = 4$ elements such that $\Omega^{(7)}$ and $\Omega^{(7)'}$ are the fixed-point sets of respective elements σ and σ' of order 2 in $\bar{G}^{(3)}$ having cycle shapes $1^4 2^4$ and disjoint fixed-point sets and the property that $\sigma\sigma'$ has order 3. Then the group of permutations of $\Omega^{(7)}$ induced by the subgroup of $\bar{G}^{(3)}$ that fixes this partition is again a copy of the group $\bar{G}^{(7)} \simeq L_2(3)$.

$$\bar{G}^{(7)} = \varrho\left(\bar{G}^{(3)}_{P^{(7)}}\right) \simeq \bar{G}^{(3)}_{P^{(7)}}/\bar{G}^{(3)}_{P^{(7)},\Omega^{(7)}} \simeq L_2(3)$$

For $\ell = 13$ the largest proper divisor of $\ell - 1 = 12$ is $6 = 7 - 1$. Choose a partition $P^{(13)} = \{\Omega^{(13)}, \Omega^{(13)'}\}$ of $\Omega^{(7)}$ into $12/6 = 2$ subsets of $4/2 = 2$ elements such that $\Omega^{(13)}$ is the orbit of an element of order 2 in $\bar{G}^{(7)}$. (That is, choose any partition of $\Omega^{(7)}$ into subsets of size 2. The elements of order 2 in $\bar{G}^{(7)}$ all have cycle shape 2^2.) Then the group of permutations of $\Omega^{(13)}$ induced by the subgroup of $\bar{G}^{(7)}$ that fixes this partition is a copy of the group $\bar{G}^{(13)} \simeq Sym_2$.

$$\bar{G}^{(13)} = \varrho\left(\bar{G}^{(7)}_{P^{(13)}}\right) \simeq \bar{G}^{(7)}_{P^{(13)}}/\bar{G}^{(7)}_{P^{(13)},\Omega^{(13)}} \simeq Sym_2$$

The next largest divisor of $13 - 1 = 12$ is $4 = 5 - 1$. An alternative construction of $\bar{G}^{(13)}$ is obtained by choosing a partition $P^{(13)} = \{\Omega^{(13)}, \Omega^{(13)'}, \Omega^{(13)''}\}$ of $\Omega^{(5)}$ into $12/4 = 3$ subsets of $6/3 = 2$ elements such that $\Omega^{(13)}$ and $\Omega^{(13)'}$ are the fixed-point sets of respective elements σ

and σ' of order 2 in $\bar{G}^{(3)}$ having cycle shapes $1^2 2^2$ and disjoint fixed-point sets and the property that $\sigma\sigma'$ has order 3. Then the group of permutations of $\Omega^{(13)}$ induced by the subgroup of $\bar{G}^{(5)}$ that fixes this partition is a copy of the group $\bar{G}^{(13)} \simeq Sym_2$.

$$\bar{G}^{(13)} = \varrho\left(\bar{G}^{(5)}_{P^{(13)}}\right) \simeq \bar{G}^{(5)}_{P^{(13)}} / \bar{G}^{(5)}_{P^{(13)},\Omega^{(13)}} \simeq Sym_2$$

Remark 3.1. The group $\bar{G}^{(\ell')}_{P^{(\ell)},\Omega^{(\ell)}}$ is trivial in every instance except for when (ℓ',ℓ) is $(2,4)$ or $(4,7)$ so apart from these cases we have $\bar{G}^{(\ell)} \simeq \bar{G}^{(\ell')}_{P^{(\ell)}}$. The group $\bar{G}^{(2)}_{P^{(4)},\Omega^{(4)}}$ has order 8 and $\bar{G}^{(4)}_{P^{(7)},\Omega^{(7)}}$ has order 4.

Remark 3.2. A *Steiner system* with parameters (t,k,n) is the data of an n-element set Ω together with a collection of subsets of Ω of size k, called the *blocks* of the system, with the property that any t-element subset of Ω is contained in a unique block. It is well-known that $M_{24} \simeq \bar{G}^{(2)}$ may be realised as the automorphism group of a Steiner system with parameters $(5,8,24)$ and $M_{12} \simeq \bar{G}^{(3)}$ may be described as the automorphism group of a Steiner system with parameters $(5,6,12)$. Indeed, for $\bar{G}^{(2)} \simeq M_{24}$ we may take the blocks to be the $\binom{24}{5}/\binom{8}{5} = 759$ sets of size 8 in a copy $\mathcal{G}$ of the Golay code on the 24 element set $\Omega = \Omega^{(2)}$ and for $\bar{G}^{(3)} \simeq M_{12}$ regarded as the subgroup of $\bar{G}^{(2)}$ preserving a set $\Omega^{(3)}$ of size 12 in $\mathcal{G}$ we may take the blocks to be the $\binom{12}{5}/\binom{6}{5} = 132$ subsets of size 6 that arise as an intersection $C \cap \Omega^{(3)}$ for $C \in \mathcal{G}$ having size 8. The group $\bar{G}^{(4)} \simeq AGL_3(2)$ also admits such a description: it is the automorphism group of the unique Steiner system with parameters $(3,4,8)$. The blocks of such a system constitute the $\binom{8}{3}/\binom{4}{3} = 14$ codewords of weight 4 in the unique doubly even linear binary code of length 8, the length 8 *Hamming code*.

Remark 3.3. Following [92, Chp. 11] let n be a divisor of 12, take n cards labelled by 0 through $n-1$ and consider the group $M_n < Sym_n$ generated by the *reverse shuffle* $r_n : t \mapsto n-1-t$ and the *Mongean shuffle* $s_n : t \mapsto \min\{2t, 2n-1-2t\}$. Then the notation is consistent with that used above, for the group M_{12} just defined is indeed isomorphic to the Mathieu group of permutations on 12 points. So we have $M_{12} \simeq \bar{G}^{(3)}$ according to Table 1 and it turns out that in fact $M_n \simeq \bar{G}^{(\ell)}$ whenever $n = 24/(\ell-1)$, and so this shuffle construction recovers all of the $\bar{G}^{(\ell)}$ except for $G^{(2)} \simeq M_{24}$ and $G^{(4)} \simeq AGL_3(2)$ (i.e. all $\bar{G}^{(\ell)}$ for ℓ odd).

3.4 Realisation Part II

Having constructed the $\bar{G}^{(\ell)}$ as permutation groups we now describe the umbral groups $G^{(\ell)}$ as groups of signed permutations. We retain the notation of §3.3.

To construct $G^{(3)}$ choose an element τ of order 11 in $\bar{G}^{(3)}$ and (re)label the elements of $\Omega^{(3)}$

so that

$$\Omega^{(3)} = \{\infty, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, X\}$$

and the action of τ on $\Omega^{(3)}$ is given by $x \mapsto x + 1$ modulo 11 (where $X = 10$). Then for any set $C \subset \Omega^{(3)}$ of size 4 there is a unique element $\sigma \in \bar{G}^{(3)}$ with cycle shape $1^4 2^4$ such that the fixed-point set of σ is precisely C. In case $C = \{0, 1, 4, 9\}$ for example $\sigma = (\infty 6)(2X)(35)(78)$ and $\bar{G}^{(3)}$ is generated by σ and τ. Let $\hat{\Omega}^{(3)} = \{e_x \mid x \in \Omega^{(3)}\}$ be a basis for a 12-dimensional vector space over $\mathbb{C}$ say, let $\hat{\tau}$ be the element of the hyperoctahedral group $Oct_{\hat{\Omega}^{(3)}} \simeq Oct_{12}$ given by $\hat{\tau} : e_x \mapsto e_{x+1}$, so that $\hat{\tau} = (0123456789X)$ in (signed) cycle notation (cf. §3.2), and set $\hat{\sigma} = (\infty 6)(\bar{2}\bar{X})(35)(\bar{7}\bar{8})$. Then for $G^{(3)}$ the group generated by $\hat{\sigma}$ and $\hat{\tau}$ we have that $G^{(3)} \simeq 2.M_{12}$ and the image of $G^{(3)}$ under the map $Oct_{\hat{\Omega}^{(3)}} \to S_{\Omega^{(3)}}$ is $\bar{G}^{(3)}$.

To construct $G^{(4)}$ choose an element τ of order 7 in $\bar{G}^{(4)}$ and (re)label the elements of $\Omega^{(4)}$ so that

$$\Omega^{(4)} = \{\infty, 0, 1, 2, 3, 4, 5, 6\}$$

and the action of τ on $\Omega^{(4)}$ is given by $x \mapsto x + 1$ modulo 7. There is a unique conjugacy class of elements of $\bar{G}^{(4)}$ having cycle shape $1^4 2^2$ and the fixed-point sets of these elements are the 14 subsets of $\Omega^{(4)}$ of size 4 comprising the blocks of a $(3, 4, 8)$ Steiner system preserved by $\bar{G}^{(4)}$ (cf. Remark 3.2). The particular block $C = \{0, 1, 3, 6\}$ is the unique one with the property that σ and τ generate $\bar{G}^{(4)}$ in case σ is any (of the 3) involution(s) with C as its fixed-point set. Take $\sigma = (\infty 5)(24)$ and let $\hat{\Omega}^{(4)} = \{e_x \mid x \in \Omega^{(4)}\}$ be a basis for an 8-dimensional vector space over $\mathbb{C}$ say, let $\hat{\tau}$ be the element of the hyperoctahedral group $Oct_{\hat{\Omega}^{(4)}} \simeq Oct_8$ given by $\hat{\tau} : e_x \mapsto e_{x+1}$, so that $\hat{\tau} = (0123456)$, and set $\hat{\sigma} = (\infty 5)(\bar{0})(\bar{1})(24)$. Then for $G^{(4)}$ the group generated by $\hat{\sigma}$ and $\hat{\tau}$ we have that $G^{(4)} \simeq 2.AGL_3(2)$ and the image of $G^{(4)}$ under the map $Oct_{\hat{\Omega}^{(4)}} \to S_{\Omega^{(4)}}$ is $\bar{G}^{(4)}$.

For the remaining $\ell \geq 5$ we can construct $G^{(\ell)}$ from $G^{(3)}$ by proceeding in analogy with the constructions of $\bar{G}^{(\ell)}$ from $\bar{G}^{(3)}$ (and its subgroups) given earlier in this section. Concretely, for $\ell = 5$ we may set

$$G^{(5)} = \hat{\varrho}\left(G^{(3)}_{\hat{P}^{(5)}}\right) \simeq G^{(3)}_{\hat{P}^{(5)}}/G^{(3)}_{\hat{P}^{(5)},\hat{\Omega}^{(5)}} \simeq GL_2(5)/2$$

where $\hat{\Omega}^{(5)} = \{e_x \mid x \in \Omega^{(5)}\}$ is a basis for $24/(5-1) = 6$-dimensional vector space over $\mathbb{C}$, we define $\hat{C} = \{e_x \mid x \in C\}$ for $C \subset \Omega^{(5)}$ and set $\hat{P}^{(5)} = \{\hat{\Omega}^{(5)}, \hat{\Omega}^{(5)\prime}\}$ for $P^{(5)} = \{\Omega^{(5)}, \Omega^{(5)\prime}\}$ as in the construction of $\bar{G}^{(5)}$ given above, the groups $G^{(3)}_{\hat{P}^{(5)}}$ and $G^{(3)}_{\hat{P}^{(5)},\hat{\Omega}^{(5)}}$ are defined by

$$G^{(3)}_{\hat{P}^{(5)}} = \left\{\sigma \in G^{(3)} \mid \sigma(\operatorname{Span}\hat{C}) \subset \operatorname{Span}\hat{C},\, \forall \hat{C} \in \hat{P}^{(5)}\right\}, \tag{3.10}$$

$$G^{(3)}_{\hat{P}^{(5)},\hat{\Omega}^{(5)}} = \left\{\sigma \in G^{(3)}_{\hat{P}^{(5)}} \mid \sigma(e_x) = e_x,\, \forall x \in \Omega^{(5)}\right\}, \tag{3.11}$$

and $\hat{\varrho}$ is the map $G^{(3)}_{\hat{P}^{(5)}} \to Oct_{\hat{\Omega}^{(5)}}$ obtained by restriction.

$$\begin{aligned} \hat{\varrho} : G^{(3)}_{\hat{P}^{(5)}} &\to Oct_{\hat{\Omega}^{(5)}} \\ \sigma &\mapsto \sigma|_{\operatorname{Span}\hat{\Omega}^{(5)}} \end{aligned} \tag{3.12}$$

In direct analogy with this we have that

$$\begin{aligned} G^{(7)} &= \hat{\varrho}\left(G^{(3)}_{\hat{P}^{(7)}}\right) \simeq G^{(3)}_{\hat{P}^{(7)}}/G^{(3)}_{\hat{P}^{(7)},\hat{\Omega}^{(7)}} \simeq SL_2(3), \\ G^{(13)} &= \hat{\varrho}\left(G^{(5)}_{\hat{P}^{(13)}}\right) \simeq G^{(5)}_{\hat{P}^{(13)}}/G^{(5)}_{\hat{P}^{(13)},\hat{\Omega}^{(13)}} \simeq 4, \end{aligned}$$

when $G^{(\ell')}_{\hat{P}^{(\ell)}}$ and $G^{(\ell')}_{\hat{P}^{(\ell)},\hat{\Omega}^{(\ell)}}$ are defined as in (3.10) and (3.11), respectively, for $P^{(\ell)} = \{\Omega^{(\ell)}, \cdots\}$ as specified in the construction of $\bar{G}^{(\ell')}$ given above, and $\hat{\varrho}$ as in (3.12).

We conclude this section with explicit signed permutation presentations of the $G^{(\ell)}$ as subgroups of the $Oct_{\hat{\Omega}^{(\ell)}}$ for $\ell \geq 3$. The presentations for $\ell = 3$ and $\ell = 4$ were obtained above, and the remaining ones can be found in a similar manner. In each case we label the index set $\Omega^{(\ell)}$ so that $\Omega^{(\ell)} = \{\infty, 0, \cdots, n-1\}$ where $n = 24/(\ell-1) - 1 = (25-\ell)/(\ell-1)$ and seek a presentation for which the coordinate permutation $e_x \mapsto e_{x+1}$ (with indices read modulo n) is an element of order n in $G^{(\ell)}$ (although we must take this element to be trivial in case $\ell = 13$).

$$G^{(3)} = \left\langle(\infty 6)(\bar{2}\bar{X})(35)(\bar{7}\bar{8}), (0123456789X)\right\rangle \tag{3.13}$$

$$G^{(4)} = \langle(\infty 5)(\bar{0})(\bar{1})(24), (0123456)\rangle \tag{3.14}$$

$$G^{(5)} = \langle(\infty\bar{0})(3\bar{1})(2\bar{4}), (01234)\rangle \tag{3.15}$$

$$G^{(7)} = \langle(\infty\bar{0})(\bar{1}2), (012)\rangle \tag{3.16}$$

$$G^{(13)} = \langle(\infty\bar{0})\rangle \tag{3.17}$$

Equipped now with explicit realisations $G^{(\ell)} < Oct_n$ of the umbral groups $G^{(\ell)}$ as signed permutation groups we define symbols $\Pi^{(\ell)}_g$, $\chi^{(\ell)}_g$, $\bar{\Pi}^{(\ell)}_g$ and $\bar{\chi}^{(\ell)}_g$ as follows for $\ell \in \Lambda$ and $g \in G^{(\ell)}$. We write $\Pi^{(\ell)}_g$ for the signed permutation Frame shape attached to $g \in G^{(\ell)}$ (when regarded as an element of Oct_n) as defined in §3.2 and we write $\bar{\Pi}^{(\ell)}_g$ for the cycle shape attached to the image of $g \in G^{(\ell)}$ under the composition $G^{(\ell)} \to Oct_n \to Sym_n$. We define $g \mapsto \chi_g^{(\ell)}$ by restricting the signed permutation character (cf. (3.3)) to $G^{(\ell)}$ and we define $g \mapsto \bar{\chi}_g^{(\ell)}$ by restricting the unsigned permutation character (cf. (3.4)) to $G^{(\ell)}$. We call $\chi_g^{(\ell)}$ the *signed twisted Euler character* attached to $g \in G^{(\ell)}$ and we call $\bar{\chi}_g^{(\ell)}$ the *unsigned twisted Euler character* attached to $g \in G^{(\ell)}$.

As is explained in §3.2 the data $g \mapsto \Pi_g^{(\ell)}$ is sufficient to determine the cycle shapes $\bar{\Pi}_g^{(\ell)}$ and the twisted Euler characters $\chi_g^{(\ell)}$ and $\bar{\chi}_g^{(\ell)}$. We will attach vector-valued mock modular forms $H_g^{(\ell)}$ to each $g \in G^{(\ell)}$ in §4 and it will develop that the shadows and multiplier systems of these functions are encoded in the Frame shapes $\Pi_g^{(\ell)}$. We list the Frame shapes $\Pi_g^{(\ell)}$ and $\bar{\Pi}_g^{(\ell)}$ and the twisted Euler characters $\chi_g^{(\ell)}$ and $\bar{\chi}_g^{(\ell)}$ for all $g \in G^{(\ell)}$ and $\ell \in \Lambda$ in the tables of §B.2.

We conclude this section with an extraordinary property relating the Frame shapes $\Pi_g^{(\ell)}$ and $\bar{\Pi}_g^{(\ell)}$ attached to the umbral groups $G^{(\ell)}$ at $\ell = 2$ and $\ell = 4$ which can be verified explicitly using the tables of §B.2.

Proposition 3.4. *Let $g \in G^{(4)}$ and suppose that the Frame shape $\Pi_g^{(4)} = \prod_k k^{m_g(k)}$ is a cycle shape, so that $m_g(k) \geq 0$ for all k. Then there exists $g' \in G^{(2)}$ with $o(g') = 2o(g)$ such that*

$$\bar{\Pi}_{g'}^{(2)} = \prod_k k^{\bar{m}_g(k)} (2k)^{m_g(k)} \tag{3.18}$$

when $\bar{\Pi}_g^{(4)} = \prod_k k^{\bar{m}_g(k)}$ except in case g is of class 4B.

As will be explained in §4 this result implies direct relationships between the functions $H_{g'}^{(2)}$ and $H_g^{(4)}$ when g and g' are as in the statement of the proposition.

3.5 Dynkin Diagrams Part I

The *McKay correspondence* [93] relates finite subgroups of $SU(2)$ to the affine Dynkin diagrams of ADE type by associating irreducible representations of the finite groups to nodes of the corresponding diagrams and by now is well understood in terms of resolutions of *simple singularities* $\mathbb{C}^2/G$ for $G < SU(2)$ [94, 95]. A more mysterious Dynkin diagram correspondence also due to McKay is his *monstrous E_8 observation* [93] (see also [96, §14]) which associates nine of the conjugacy classes of the monster group to the nodes of the affine E_8 Dynkin diagram and extends to similar correspondences relating certain subgroups of the Monster to other affine Dynkin diagrams [97]. We find analogues of both McKay's Dynkin diagram observations manifesting in the groups $G^{(\ell)}$, as we shall now explain.

For $\ell \in \Lambda = \{2, 3, 4, 5, 7, 13\}$ the number $(25 - \ell)/(\ell - 1)$ is an odd integer p such that $p + 1$ divides 24 and is a prime in case ℓ is not 13. Recall the construction of $\bar{G}^{(\ell)}$ as permutations of

$\Omega^{(\ell)}$ from §3.3. By inspection, with the assistance of [98], we obtain the following lemma.

Lemma 3.5. *Let $\ell \in \{2,3,4,5,7\}$ and set $p = (25-\ell)/(\ell-1)$. Then the group $\bar{G}^{(\ell)}$ has a unique conjugacy class of subgroups isomorphic to $L_2(p)$ that act transitively on the degree $p+1 = 24/(\ell-1)$ permutation representation of $\bar{G}^{(\ell)}$ on $\Omega^{(\ell)}$.*

Armed with Lemma 3.5 we pick a transitive subgroup of $\bar{G}^{(\ell)}$ isomorphic to $L_2(p)$ for each ℓ in $\{2,3,4,5,7\}$—these being the cases that $(25-\ell)/(\ell-1)$ is prime—and denote it $\bar{L}^{(\ell)}$. For future reference we note that there are two conjugacy classes of subgroups of $\bar{G}^{(\ell)}$ isomorphic to $L_2(p)$ in case $\ell \in \{3,4\}$ but in each case only one of these classes contains subgroups acting transitively.

Lemma 3.6. *For $\ell \in \{3,4\}$ and $p = (25-\ell)/(\ell-1)$ there is a unique conjugacy class of subgroups of $\bar{G}^{(\ell)}$ isomorphic to $L_2(p)$ that does not act transitively in the degree $p+1 = 24/(\ell-1)$ permutation representation of $\bar{G}^{(\ell)}$ on the set $\Omega^{(\ell)}$.*

It is a result due to Galois (proven in a letter to Chevalier written on the eve of his deadly duel [92, Chp. 10]) that the group $L_2(p)$ has no transitive permutation representation of degree less than $p+1$ if $p > 11$. However for the remaining primes p not exceeding 11 there are transitive permutation representations on exactly p points, and in fact we have the following statement.

Lemma 3.7. *Let $p \in \{2,3,5,7,11\}$ and set $\bar{L} = L_2(p)$. Then there is a subgroup $\bar{D} < \bar{L}$ of index p with the property that $\bar{L} = \langle\sigma\rangle\bar{D}$ for σ an element of order p in $\bar{L}$, so that every element $g \in \bar{L}$ admits a unique expression $g = sd$ where $s \in \langle\sigma\rangle$ and $d \in \bar{D}$.*

Remark 3.8. See [92, Chp. 10] for applications of the result of Lemma 3.7 to exceptional isomorphisms among finite simple groups of small order, and see [99, 100] for an application of the case that $p = 11$ to the truncated icosahedron (which describes the structure of buckminsterfullerenes, a.k.a. buckyballs).

According to Lemma 3.7 we obtain a permutation representation of degree p for $\bar{L}$ by taking the natural action of $\bar{L}$ on cosets of $\bar{D}$ and this action is transitive since σ induces a p-cycle. Using this result we choose a copy of $\bar{D}$ in $\bar{L} = \bar{L}^{(\ell)}$ for each $\ell \in \{3,4,5,7\}$ and denote it $\bar{D}^{(\ell)}$. (Such subgroups are uniquely determined up to isomorphism, but there are as many conjugacy classes of subgroups of $\bar{L}$ isomorphic to $\bar{D}$ as there are conjugacy classes of elements of order p in $\bar{L}$, which is to say there are 2 classes in case $p \in \{11,7\}$ and a unique class in case $p \in \{5,3\}$.) We describe the groups $\bar{D}^{(\ell)}$ in Table 2 and observe that each one is isomorphic to a finite group $\bar{D}_0 < SO_3(\mathbb{R})$. As such there is a corresponding finite group $D_0 < SU(2)$ that maps onto $\bar{D}_0$

Table 2: The Umbral Groups and Dynkin Data

$\bar{D}^{(\ell)}$		Alt_5	Sym_4	Alt_4	2^2	
$\Delta^{(\ell)}$		$\hat{E}_8$	$\hat{E}_7$	$\hat{E}_6$	$\hat{D}_4$	

via the 2-fold covering $SU(2) \to SO_3(\mathbb{R})$, and a corresponding Dynkin diagram $\Delta^{(\ell)}$ according to the McKay correspondence. We list the Dynkin diagrams $\Delta^{(\ell)}$ also in Table 2.

Traditionally finite subgroups of $SO_3(\mathbb{R})$ are called *ternary*, owing to the fact that their elements are described using 3×3 matrices, and finite subgroups of $SU(2)$ are called *binary*. The map $SU(2) \to SO_3(\mathbb{R})$ determines a correspondence between binary and ternary groups whereby the ternary polyhedral groups (of orientation preserving symmetries of regular polyhedra) correspond to binary groups of the form $2.Alt_5$, $2.Sym_4$ and $2.Alt_4$ (depending upon the polyhedron), a dihedral subgroup $Dih_n < SO_3(\mathbb{R})$ corresponds to a generalised quaternion group of order $4n$ in $SU(2)$, and a binary cyclic group corresponds to a ternary cyclic group of the same order. Thus, given a finite subgroup $\bar{D}_0 < SO_3(\mathbb{R})$, we may speak of the *associated binary group* $D_0 < SU(2)$.

Next we observe that each group $G^{(\ell)}$ contains a subgroup $D^{(\ell)}$ isomorphic to the binary group associated to $\bar{D}^{(\ell)}$ (when $\bar{D}^{(\ell)}$ is regarded as a subgroup of $SO_3(\mathbb{R})$) for all of the above cases except when $\ell = p = 5$. More particularly, for $\ell \in \{3, 7\}$ there is a unique conjugacy class of subgroups isomorphic to the binary group attached to $\bar{D}^{(\ell)}$ while for $\ell = 4$ there are two such conjugacy classes and for $\ell = 5$ there are none. For each $\ell \in \{3, 4, 7\}$ we pick a subgroup isomorphic to the binary group attached to $\bar{D}^{(\ell)}$ and denote it $D^{(\ell)}$ and we display the (isomorphism types of the) groups $D^{(\ell)}$ in Table 2. We write Q_8 there for the quaternion group of order 8.

To see how the $D^{(\ell)}$ arise in $G^{(\ell)}$ (and fail to do so in the case that $\ell = 5$) recall from Lemma 3.5 that $\bar{G}^{(\ell)}$ contains a unique transitive subgroup isomorphic to $L_2(p)$ up to conjugacy for $\ell \in \{3, 4, 5, 7\}$. The preimage of such a subgroup under the natural map $G^{(\ell)} \to \bar{G}^{(\ell)}$ (cf. §3.4) is a double cover of $L_2(p)$ that is in fact isomorphic to $SL_2(p)$ (cf. §3.1) except when $\ell = 5$. In case $\ell = 5$ we have $G^{(5)} \simeq GL_2(5)/2$ which has the same order as $SL_2(5)$ but is not isomorphic to it. We see then that for $\ell \in \{3,4,7\}$ we may find a copy of $SL_2(p)$ in the preimage of $\bar{L}^{(\ell)}$ under the map $G^{(\ell)} \to \bar{G}^{(\ell)}$; we do so and denote it $L^{(\ell)}$. Then we may take $D^{(\ell)}$ to be the preimage of $\bar{D}^{(\ell)}$ under the map $L^{(\ell)} \to \bar{L}^{(\ell)}$. The fact that there is no $SL_2(5)$ in $G^{(5)}$ explains why there is no group $D^{(5)}$.

Observe that the rank of $\Delta^{(\ell)}$ is given by $11-\ell$ for each $\ell \in \{3,4,5,7\}$. This may be taken as a hint to the following uniform construction of the $\Delta^{(\ell)}$. Starting with the (finite type) E_8 Dynkin diagram, being star shaped with three *branches*, construct a sequence of diagrams iteratively by removing the end node from a branch of maximal length at each iteration. In this way we obtain the sequence E_8, E_7, E_6, D_5, D_4, A_3, A_2, A_1, and it is striking to observe that our list $\Delta^{(\ell)}$, obtained by applying the McKay correspondence to distinguished subgroups of the $G^{(\ell)}$, is a subsequence of the one obtained from this by affinisation.

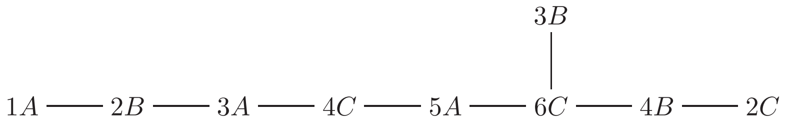
We summarise the main observations of this section as follows.

> *For $\ell \in \{3,4,5,7\}$ the group $\bar{G}^{(\ell)}$ admits a distinguished isomorphism class of subgroups $\bar{D}^{(\ell)}$. This connects $\bar{G}^{(\ell)}$ to a Dynkin diagram of rank $11-\ell$, for the group $\bar{D}^{(\ell)}$ is the image in $SO_3(\mathbb{R})$ of a finite subgroup $D^{(\ell)}$ in $SU(2)$ which corresponds to the affinisation $\Delta^{(\ell)}$ of a Dynkin diagram of rank $11-\ell$ according to McKay's correspondence. The Dynkin diagrams arising belong to a naturally defined sequence.*

3.6 Dynkin Diagrams Part II

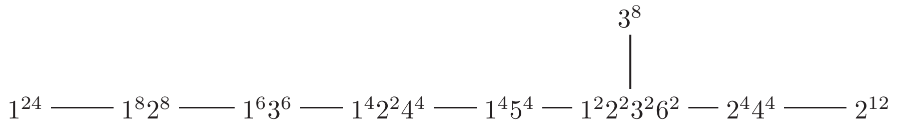
Recall from Lemma 3.6 that the cases $\ell \in \{3,4\}$ are distinguished in that for such ℓ the group $\bar{G}^{(\ell)}$ has a unique conjugacy class of subgroups isomorphic to $L_2(p)$ and not acting transitively in the degree $p+1$ permutation representation (cf. §3.3). Since such an $L_2(p)$ subgroup acts non-trivially on $\Omega^{(\ell)}$ it follows from Lemma 3.7 that it must have one fixed point and act transitively on the remaining p points of $\Omega^{(\ell)}$, and thus we have witnesses within $G^{(\ell)}$ to the exceptional degree p permutation representations of $L_2(p)$ in case $\ell \in \{3,4\}$ and $p \in \{11,7\}$. For these two special cases of lambency 3 and 4 we find direct analogues of McKay's monstrous E_8 observation [93] attaching certain conjugacy classes of $G^{(\ell)}$ to the nodes of $\Delta^{(\ell)}$. At lambency 5 and 7 (where p is 5 and 3, respectively) we find similar analogues where the diagram $\Delta^{(\ell)}$ is replaced by one obtained via folding with respect to a diagram automorphism of order 3.

In case $\ell = 3$ let T denote the conjugacy class of elements g of order 2 in $G^{(3)} \simeq 2.M_{12}$ such that g has 4 fixed points in both the signed and unsigned permutation representations of $G^{(3)}$. This is the conjugacy class labelled $2B$ in Table 9 and we have $\chi_g^{(3)} = \bar{\chi}_g^{(3)} = 4$ in the notation of Table 15. Then $T^2 = \{gh \mid g,h \in T\}$ is a union of conjugacy classes of $G^{(3)}$ and in fact there are exactly nine of the twenty-six conjugacy classes of $G^{(3)}$ that appear. In (3.19) we use these classes (and the notation of Table 9) to label the affine E_8 Dynkin diagram.



(3.19)

Observe that the labelling of (3.19) recovers the highest root labelling when the classes are replaced with their orders. In (3.20) we replace the labels of (3.19) with the cycle shapes attached to these classes via the total permutation action (cf. §3.2) of $G^{(3)}$ on the $24 = 2.24/(\ell - 1)$ elements $\{\pm e_i \mid i \in \Omega^{(3)}\}$ appearing in the signed permutation representation of $G^{(3)}$ (cf. §3.4).



(3.20)

Explicitly, the cycle shape attached to $g \in G^{(3)}$ is the total permutation Frame shape $\tilde{\Pi}_g^{(3)} = \Pi_g^{(3)} \bar{\Pi}_g^{(3)}$ realised as the product (cf. §3.2) of the signed and unsigned permutation Frame shapes attached to $G^{(3)}$ (cf. Table 15).

Remark 3.9. The conjugacy class labelled $2C$ in Table 9 consists of elements of the form gz where g belongs to the class $2B$ (denoted T above) and z is the central involution of $G^{(3)}$, so we obtain exactly the nine conjugacy classes of (3.19) by considering products gh where g and h are involutions in the class $2C$.

Remark 3.10. In [101] an analogue of McKay's monstrous E_8 observation is found for M_{24}. Namely, it is observed that there are exactly nine conjugacy classes of elements of M_{24} having representatives of the form gh where g and h belong to the class labelled 2A in Table 8—this is the class with cycle shape $1^8 2^8$ in the defining degree 24 permutation representation—and the nodes of the affine E_8 Dynkin diagram can be labelled by these nine classes in such a way that their orders recover the highest root labelling. This condition leaves some ambiguity as to the correct placement of the two classes of order 2, and similarly for the pairs of orders 3 and 4, but an analogue of the procedure described in [102] is shown to determine a particular choice that recovers the original correspondence for the monster group via the modular functions of monstrous moonshine. Observe that if we express the $G^{(2)} \simeq M_{24}$ labelling of the affine E_8 diagram given in [101] using cycle shapes to name the conjugacy classes then we recover exactly the labelling (3.20) obtained here from $G^{(3)} \simeq 2.M_{12}$.

In case $\ell = 4$ let T denote the conjugacy class of elements g of order 2 in $G^{(4)}$ such that

g has 4 fixed points in the unsigned permutation representation of $G^{(4)}$ but has 2 fixed points and 2 anti-fixed points in the signed permutation representation. This is the conjugacy class labelled $2C$ in Table 10 and we have $\chi_g^{(4)}=0$ and $\bar{\chi}_g^{(4)}=4$ in the notation of Table 16. Then T^2 is the union of eight of the sixteen conjugacy classes of $G^{(4)}$ and we use these classes (and the notation of Table 10) to label the nodes of the affine E_7 Dynkin diagram in (3.21).

$$\begin{tikzcd}
 & & & 2B & & & \\
1A \arrow[r, dash] & 2C \arrow[r, dash] & 3A \arrow[r, dash] & 4C \arrow[u, dash] \arrow[r, dash] & 6A \arrow[r, dash] & 4A \arrow[r, dash] & 2A
\end{tikzcd} \tag{3.21}$$

In (3.22) we replace the labels of (3.21) with the cycle shapes $\bar{\Pi}_g^{(4)}$ (cf. Table 16) attached to these classes via the degree 8 permutation action of $G^{(4)}$ on $\Omega^{(4)}$. The orders of these permutations are the orders of the images of the corresponding elements of $G^{(4)}$ under the map $G^{(4)} \to \bar{G}^{(4)}$ so the labelling (3.22) demonstrates that we recover the highest root labelling of the affine E_7 Dynkin diagram when we replace the conjugacy classes of (3.21) with the orders of their images in $\bar{G}^{(4)}$.

$$\begin{tikzcd}
 & & & 2^4 & & & \\
1^8 \arrow[r, dash] & 1^4 2^2 \arrow[r, dash] & 1^2 3^2 \arrow[r, dash] & 1^2 2^1 4^1 \arrow[u, dash] \arrow[r, dash] & 1^2 3^2 \arrow[r, dash] & 2^4 \arrow[r, dash] & 1^8
\end{tikzcd} \tag{3.22}$$

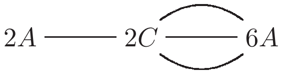
In (3.23) we replace the labels of (3.21) with the cycle shapes of degree 24 given by the products $\Pi_g^{(4)}\bar{\Pi}_g^{(4)}\bar{\Pi}_g^{(4)}$ (cf. Table 16) for g an element of $G^{(4)}$ arising in (3.21). Observe that all the cycle shapes in (3.23) are *balanced*, meaning that they are invariant (and well-defined) under the operation $\prod_{k\geq 1} k^{m(k)} \mapsto \prod_{k\geq 1}(N/k)^{m(k)}$ for some integer $N>1$, and constitute a subset of the cycle shapes attached to $G^{(3)}$ in (3.20). Observe also that the order two symmetry of the affine E_7 diagram that identifies the two long branches is realised by squaring: the cycle shapes obtained by squaring permutations represented by the cycle shapes on the right-hand branch of (3.23) are just those that appear on the left-hand branch.

$$\begin{tikzcd}
 & & & 2^{12} & & & \\
1^{24} \arrow[r, dash] & 1^8 2^8 \arrow[r, dash] & 1^6 3^6 \arrow[r, dash] & 1^4 2^2 4^4 \arrow[u, dash] \arrow[r, dash] & 1^2 2^2 3^2 6^2 \arrow[r, dash] & 2^4 4^4 \arrow[r, dash] & 1^8 2^8
\end{tikzcd} \tag{3.23}$$

Remark 3.11. It is interesting to note that while the conjugacy class $2C$ is stable under multiplication by the central involution there are just eight conjugacy classes of $G^{(4)}$ that are contained in T^2 when T is the class labelled $4A$ in Table 10. In fact the eight conjugacy classes appearing are $8A$ together with all those of (3.21) except for $4C$. Thus we obtain analogues of the labelings (3.21), (3.22) and (3.23) where $4C$, $1^2 2^1 4^1$ and $1^4 2^2 4^4$, respectively, are replaced by $8A$, 4^2 and $4^2 8^2$, respectively. Under this correspondence the highest root labelling is again obtained by taking orders in $\bar{G}^{(4)}$, but while the eta product attached to $4^2 8^2$ is multiplicative it only has weight 2 (i.e. less than 4) and so does not appear in [101].

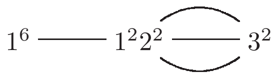
Remark 3.12. The correspondence of [101] may be viewed as attaching the nine multiplicative eta products of weight at least 4 to the nodes of the affine E_8 Dynkin diagram when we regard a cycle shape $\prod_{k\geq 1} k^{m(k)}$ as a shorthand for the *eta product* function $\prod_{k\geq 1} \eta(k\tau)^{m(k)}$ (cf. §A.1). Observe that the cycle shapes appearing in (3.23) are just those whose corresponding eta products are multiplicative, have weight at least 4, and have level dividing 24. (The eta products defined by $1^4 5^4$ and 3^8 have level 5 and 9, respectively.)

For $\ell = 5$ the Dynkin diagram $\Delta^{(5)} = \hat{E}_6$ admits a *Sym*$_3$ group of automorphisms. Folding by either of the three-fold symmetries we obtain the affine Dynkin diagram of type G_2. Let T be either of the two conjugacy class of elements g of order 4 in $G^{(5)}$ such that g^2 is central. Then we have $\chi_g^{(5)} = \bar{\chi}_g^{(5)} = 0$ in the notation of Table 17 and T is either the class labelled $4A$ in Table 11 or the class labelled $4B$, and there are exactly three of the fourteen conjugacy classes of $G^{(5)}$ that are subsets of T^2. In (3.24) we use these classes (and the notation of Table 11) to label the affine G_2 Dynkin diagram.



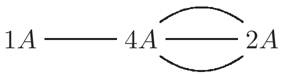
(3.24)

In (3.25) we replace the labels of (3.24) with the cycle shapes $\bar{\Pi}_g^{(5)}$ (cf. Table 17) attached to these classes via the degree 6 permutation action of $G^{(5)}$ on $\Omega^{(5)}$. The orders of these permutations are the orders of the images of the corresponding elements of $G^{(5)}$ under the map $G^{(5)} \to \bar{G}^{(5)}$ so the labelling (3.25) demonstrates that we recover the highest root labelling of the affine G_2 Dynkin diagram—which is the labelling induced form the highest root labelling of $\hat{E}_6$—when we replace the conjugacy classes of (3.24) with the orders of their images in $\bar{G}^{(5)}$.



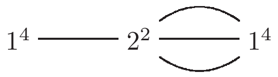
(3.25)

For $\ell = 7$ the Dynkin diagram $\Delta^{(7)} = \hat{D}_4$ admits a *Sym*$_4$ group of automorphisms. Folding by any three-fold symmetry we again obtain the affine Dynkin diagram of type G_2. Let T be the unique conjugacy class of elements of order 4 in $G^{(7)}$. Then we have $\chi_g^{(7)} = \bar{\chi}_g^{(7)} = 0$ in the notation of Table 18 and T is the class labelled $4A$ in Table 12, and there are exactly three of the seven conjugacy classes of $G^{(7)}$ that have a representative of the form gh for some $g, h \in T$ (and T^2 is the union of these three conjugacy classes). In (3.26) we use these classes (and the notation of Table 12) to label the affine G_2 Dynkin diagram.



(3.26)

In (3.27) we replace the labels of (3.26) with the cycle shapes $\bar{\Pi}_g^{(7)}$ (cf. Table 18) attached to these classes via the degree 4 permutation action of $G^{(7)}$ on $\Omega^{(7)}$. The orders of these permutations are the orders of the images of the corresponding elements of $G^{(7)}$ under the map $G^{(7)} \to \bar{G}^{(7)}$ so the labelling (3.27) demonstrates that we recover the labelling of the affine G_2 Dynkin diagram that is induced by the highest root labelling of $\hat{D}_4$ when we replace the conjugacy classes of (3.26) with the orders of their images in $\bar{G}^{(7)}$.



(3.27)

We summarise the results of this section with the following statement.

> *For $\ell \in \{3, 4, 5, 7\}$ there is an analogue of McKay's monstrous E_8 observation that relates $G^{(\ell)}$ to (a folding of) the affinisation of a Dynkin diagram of rank $11 - \ell$, and the diagrams arising are precisely those that appear in §3.5.*

We conclude by mentioning that McKay's monstrous observation has partially been explained, using vertex operator algebra theory, by the work of Sakuma [103] and Lam–Yamada–Yamauchi [104, 105]. Important related work appears in [106, 107].

4 McKay–Thompson Series

In §2.5 we made the observation that the first few positive degree Fourier coefficients of the vector-valued mock modular forms $H^{(\ell)} = \left(H_r^{(\ell)}\right)$ coincide (up to a factor of 2) with dimensions of irreducible representations of the group $G^{(\ell)}$ described in the previous section. This observation suggests the possibility that

$$H_r^{(\ell)}(\tau) = \sum_{k \in \mathbb{Z}} c_r^{(\ell)}(k - r^2/4\ell) q^{k - r^2/4\ell} = -2\delta_{r,1} q^{-1/4\ell} + \sum_{\substack{k \in \mathbb{Z} \\ r^2 - 4k\ell < 0}} \dim K^{(\ell)}_{r, k - r^2/4\ell} q^{k - r^2/4\ell} \tag{4.1}$$

for some $\mathbb{Z} \times \mathbb{Q}$-graded infinite-dimensional $G^{(\ell)}$-module $K^{(\ell)} = \bigoplus_{r,d} K^{(\ell)}_{r,d}$. To further test this possibility we would like to see if there are similar vector-valued mock modular forms

$H_g^{(\ell)} = \big(H_{g,r}^{(\ell)}\big)$ whose positive degree Fourier coefficients recover characters of representations of $G^{(\ell)}$. In other words, for an element g of the group $G^{(\ell)}$ we would like to see if we can find a mock modular form $H_g^{(\ell)}$ compatible with the hypothesis that

$$H_{g,r}^{(\ell)}(\tau) = \sum_k c_{g,r}^{(\ell)}(k - r^2/4\ell)q^{k-r^2/4\ell} = -2\delta_{r,1}q^{-1/4\ell} + \sum_{\substack{k\in\mathbb{Z}\\ r^2-4k\ell<0}} \mathrm{tr}_{K^{(\ell)}_{r,k-r^2/4\ell}}(g)q^{k-r^2/4\ell} \tag{4.2}$$

for a hypothetical bi-graded $G^{(\ell)}$-module $K^{(\ell)}$. We refer to such a generating function as a *McKay–Thompson series*. Notice that we recover the generating functions of the $\dim K_{r,d}^{(\ell)}$ when g is the identity element. Moreover, the McKay–Thompson series attached to $g \in G^{(\ell)}$ is invariant under conjugation, since the trace is such, so $H_g^{(\ell)}$ depends only on the conjugacy class $[g]$ of g.

Having such McKay–Thompson series for each conjugacy class of $G^{(\ell)}$ not only provides strong evidence for the existence of the $G^{(\ell)}$-module $K^{(\ell)}$ but in fact it uniquely specifies it up to $G^{(\ell)}$-module isomorphism. This is because, since there are as many irreducible representations as conjugacy classes of a finite group, given the characters $\mathrm{tr}_{K_{r,d}^{(\ell)}}(g)$ for all $[g] \subset G^{(\ell)}$ we can simply invert the character table to have a unique decomposition of the conjectural module $K_{r,d}^{(\ell)}$ into irreducible representations. What is not clear, a priori, is that we will end up with a decomposition into non-negative integer multiples of irreducible representations of $G^{(\ell)}$, but remarkably it appears that this property holds for all $\ell \in \Lambda$ and all bi-degrees (r, d). For evidence in support of this see the explicit decompositions for small degrees tabulated in §D.

In this section we construct a set of vector-valued mock modular forms $H_g^{(\ell)} = \big(H_{g,r}^{(\ell)}\big)$ for each lambency ℓ and we formulate a precise conjecture implying (4.2) in §5.1.

4.1 Forms of Higher Level

In §2 we have discussed the relation between certain vector-valued mock modular forms, meromorphic Jacobi forms of weight 1 and Jacobi forms of weight 0 under the group $SL_2(\mathbb{Z})$. In order to investigate the McKay–Thompson series of the groups $G^{(\ell)}$ we need to generalise the discussion in §2.5 to modular forms of higher level and consider forms transforming under $\Gamma_0(N)$ (cf. (A.2)) with $N > 1$.

As in §2 we would like to consider $(\ell - 1)$-vector-valued mock modular forms $\big(H_{g,r}^{(\ell)}\big)$ for a group $\Gamma_0(N_g) < SL_2(\mathbb{Z})$ with shadow given by the unary theta series $S^{(\ell)}$ (cf. (2.26)). The levels N_g will be specified explicitly for all g in §4.8. A first difference between the case of $N_g = 1$ and $N_g > 1$ is the following. Since the components of $S^{(\ell)} = \big(S_r^{(\ell)}\big)$ have more than one orbit under $\Gamma_0(N_g)$ when N_g is even it is natural to consider mock modular forms with shadows given by

$\big(\chi_{g,r}^{(\ell)} S_r^{(\ell)}\big)$ where the $\chi_{g,r}^{(\ell)}$ are not necessarily equal for different values of r. It will develop that in the cases of interest to us $\chi_{g,r}^{(\ell)}$ depends only on r modulo 2. In fact, we will find that

$$\chi_{g,r}^{(\ell)} = \begin{cases} \chi_g^{(\ell)}, & \text{for } r \equiv 0 \pmod 2; \\ \bar{\chi}_g^{(\ell)}, & \text{for } r \equiv 1 \pmod 2; \end{cases} \tag{4.3}$$

where $\chi_g^{(\ell)}$ and $\bar{\chi}_g^{(\ell)}$ are as defined in §3.4 and as tabulated in §B.2.

Group theoretically the multiplicities $\bar{\chi}_g^{(\ell)}$ and $\chi_g^{(\ell)}$ appearing in the shadow of $H_g^{(\ell)}$ are determined by the number of fixed points and anti-fixed points in the signed permutation representation of the group $G^{(\ell)}$, as explained in §3.2. For instance, we have $\bar{\chi}_g^{(\ell)} = \chi_g^{(\ell)} = \chi^{(\ell)}$ for the identity element $g = e$. From this interpretation we can deduce that the vanishing of $\bar{\chi}_g^{(\ell)}$ implies the vanishing of $\chi_g^{(\ell)}$, while it is possible to have $\chi_g^{(\ell)} = 0$ and $\bar{\chi}_g^{(\ell)} \neq 0$. It will also turn out that

$$\bar{\chi}_g^{(\ell)} = \chi_g^{(\ell)} \quad \text{unless} \quad 2|N_g. \tag{4.4}$$

For later use we define the combinations

$$\chi_{g,+}^{(\ell)} = \tfrac{1}{2}\big(\bar{\chi}_g^{(\ell)} + \chi_g^{(\ell)}\big), \quad \chi_{g,-}^{(\ell)} = \tfrac{1}{2}\big(\bar{\chi}_g^{(\ell)} - \chi_g^{(\ell)}\big), \tag{4.5}$$

which enumerate the number of fixed and anti-fixed points, respecitlvely, in the signed permutation representation of $G^{(\ell)}$ (cf. (3.3-3.4)). Of course in the cases where $\bar{\chi}_g^{(\ell)} = \chi_g^{(\ell)} = 0$ the function $H_g^{(\ell)} = \big(H_{g,r}^{(\ell)}\big)$ has vanishing shadow and is a vector-valued modular form in the usual sense.

Interestingly, just as in the $SL_2(\mathbb{Z})$ case that was considered in §2.3, the higher level vector-valued mock modular forms with shadows as described above are again closely related to the finite parts of meromorphic Jacobi forms of weight 1. More explicitly, from the transformation (2.29) and the simple fact $\theta_r^{(\ell)}(\tau, z + 1/2) = (-1)^r \theta_r^{(\ell)}(\tau, z)$ it is not difficult to check that the function

$$\psi_g^{(\ell)}(\tau, z) = \chi_{g,+}^{(\ell)} \mu_0^{(\ell)}(\tau, z) - \chi_{g,-}^{(\ell)} \mu_0^{(\ell)}(\tau, z + 1/2) + \sum_{r=1}^{\ell-1} H_{g,r}^{(\ell)}(\tau) \hat{\theta}_r^{(\ell)}(\tau, z) \tag{4.6}$$

transforms as a Jacobi form of weight 1 and index ℓ under the congruence subgroup $\Gamma_0(N_g)$ when $H_g^{(\ell)}$ is a mock modular form of weight 1/2 for $\Gamma_0(N_g)$ with shadow $S_g^{(\ell)} = \big(\chi_{g,r}^{(\ell)} S_r^{(\ell)}\big)$. Observe that, for those g with both $\chi_{g,+}^{(\ell)}$ and $\chi_{g,-}^{(\ell)}$ being non-zero, the weak Jacobi form $\psi_g^{(\ell)}(\tau, z)$ has a pole not only at $z=0$ but also at $z=1/2$. From

$$\mu_0^{(\ell)}(\tau,z)=\mathrm{Av}^{(\ell)}\left[\frac{y+1}{y-1}\right],\quad -\mu_0^{(\ell)}(\tau,z+1/2)=\mathrm{Av}^{(\ell)}\left[\frac{1-y}{1+y}\right],\tag{4.7}$$

we see that the last two terms of the decomposition given in (4.6) have the interpretation as the polar parts at the poles $z=0$ and $z=1/2$, respectively. In other words, we again have a decomposition $\psi_g^{(\ell)}=\psi_g^{(\ell),P}+\psi_g^{(\ell),F}$ into polar and finite parts given by

$$\begin{aligned}\psi_g^{(\ell),P}(\tau,z)&=\chi_{g,+}^{(\ell)}\mu_0^{(\ell)}(\tau,z)-\chi_{g,-}^{(\ell)}\mu_0^{(\ell)}(\tau,z+1/2),\\ \psi_g^{(\ell),F}(\tau,z)&=\sum_{r=1}^{\ell-1}H_{g,r}^{(\ell)}(\tau)\hat\theta_r^{(\ell)}(\tau,z),\end{aligned}\tag{4.8}$$

and the components $H_{g,r}^{(\ell)}$ of the mock modular form $H_g^{(\ell)}$ may again be interpreted as the theta-coefficients of a meromorphic Jacobi form; namely, $\psi_g^{(\ell)}(\tau,z)$.

Moreover, analogous to the $SL_2(\mathbb{Z})$ case, the mock modular form $H_g^{(\ell)}$ also enjoys a close relationship with a weight 0 index $\ell-1$ weak Jacobi form $Z_g^{(\ell)}$ which admits a decomposition into characters of the $N=4$ superconformal algebra at level $\ell-1$. To see this, observe that

$$\psi_g^{(\ell)}(\tau,z)=\frac{\chi_{g,+}^{(\ell)}}{\bar\chi_g^{(\ell)}}\,\Psi_{1,1}(\tau,z)\,Z_g^{(\ell)}(\tau,z)-\frac{\chi_{g,-}^{(\ell)}}{\bar\chi_g^{(\ell)}}\,\Psi_{1,1}(\tau,z+1/2)\,Z_g^{(\ell)}(\tau,z+1/2)\tag{4.9}$$

when $\bar\chi_g^{(\ell)}\neq 0$ and

$$\psi_g^{(\ell)}(\tau,z)=\Psi_{1,1}(\tau,z)\,Z_g^{(\ell)}(\tau,z)\tag{4.10}$$

when $\bar\chi_g^{(\ell)}=0$, where $\Psi_{1,1}(\tau,z)$ is as in (2.20) and $Z_g^{(\ell)}$ is the weak Jacobi form of weight 0 and index $\ell-1$ given by

$$Z_g^{(\ell)}(\tau,z)=\frac{1}{\Psi_{1,1}(\tau,z)}\left(\bar\chi_g^{(\ell)}\mu_0^{(\ell)}(\tau,z)+\sum_{0<r<\ell}\left(1+\frac{\bar\chi_g^{(\ell)}-\chi_{g,r}^{(\ell)}}{\chi_g^{(\ell)}}\right)H_{g,r}^{(\ell)}(\tau)\hat\theta_r^{(\ell)}(\tau,z)\right)\tag{4.11}$$

for $\chi_g^{(\ell)}\neq 0$ and

$$Z_g^{(\ell)}(\tau,z)=\frac{1}{\Psi_{1,1}(\tau,z)}\left(\bar\chi_g^{(\ell)}\mu_0^{(\ell)}(\tau,z)+\sum_{0<r<\ell}H_{g,r}^{(\ell)}(\tau)\hat\theta_r^{(\ell)}(\tau,z)\right)\tag{4.12}$$

otherwise.

Anticipating their relation to the conjugacy classes $[g]$ of $G^{(\ell)}$, another comment on the weight 0 forms $Z_g^{(\ell)}$ is in order here. As discussed in §3.2, if $\ell\in\Lambda$ and $\ell>2$ then $G^{(\ell)}$ has a unique central element z of order 2 and for any $g \in G^{(\ell)}$ the conjugacy casses $[g]$ and $[zg]$ are said to be paired, and a class $[g]$ is said to be self-paired if $[g] = [zg]$. We have

$$\bar{\chi}_g^{(\ell)} = \bar{\chi}_{zg}^{(\ell)}, \quad \chi_g^{(\ell)} = -\chi_{zg}^{(\ell)}, \tag{4.13}$$

and as a consequence $Z_g^{(\ell)}(\tau, z) = Z_{zg}^{(\ell)}(\tau, z)$. Therefore, while the vector-valued mock modular forms $H_g^{(\ell)}$ and the weight 1 meromorphic Jacobi forms $\psi_g^{(\ell)}(\tau, z)$ are generally distinct for different conjugacy classes $[g]$ of the group $G^{(\ell)}$, the weight 0 index $\ell - 1$ weak Jacobi forms $Z_g^{(\ell)}$ cannot distinguish between two classes that are paired in the above sense and are more naturally associated to the group $\bar{G}^{(\ell)}$ which is the quotient of $G^{(\ell)}$ by the subgroup $\langle z \rangle$.

Equipped with the $H^{(\ell)}$ defined in terms of decompositions of Jacobi forms as discussed in §2.5 it will develop that a convenient way to specify the vector-valued mock modular forms $H_g^{(\ell)} = \left(H_{g,r}^{(\ell)}\right)$ corresponding to non-identity conjugacy classes of $G^{(\ell)}$ will be to specify certain sets of weight 2 modular forms. To see how a weight 2 modular form is naturally associated with a vector-valued modular form with the properties described above, observe that we can eliminate the presence of the polar part in the weight 1 Jacobi form $\psi_g^{(\ell)}(\tau, z)$ (cf. (4.6)) by taking a linear combination with $\psi^{(\ell)}(\tau, z)$. To be more precise, note that

$$\hat{\psi}_g^{(\ell)}(\tau, z) = \sum_{r=1}^{\ell-1} \hat{H}_{g,r}^{(\ell)}(\tau) \hat{\theta}_r^{(\ell)}(\tau, z) = \psi_g^{(\ell)}(\tau, z) - \frac{\chi_{g,+}^{(\ell)}}{\chi^{(\ell)}} \psi^{(\ell)}(\tau, z) + \frac{\chi_{g,-}^{(\ell)}}{\chi^{(\ell)}} \psi^{(\ell)}(\tau, z + 1/2) \tag{4.14}$$

is a weight 1 index ℓ Jacobi form for $\Gamma_0(N_g)$ with no poles in z, and the functions

$$\hat{H}_{g,r}^{(\ell)}(\tau) = H_{g,r}^{(\ell)}(\tau) - \frac{\chi_{g,r}^{(\ell)}}{\chi^{(\ell)}} H_r^{(\ell)}(\tau) \tag{4.15}$$

are the components of a vector-valued modular form $\hat{H}_g^{(\ell)}$ for $\Gamma_0(N_g)$ in the usual sense (i.e. a mock modular form with vanishing shadow). From this we readily conclude that the function

$$F_g^{(\ell)}(\tau) = \sum_{r=1}^{\ell-1} \hat{H}_{g,r}^{(\ell)}(\tau) S_r^{(\ell)}(\tau) = -\frac{1}{4\pi i} \frac{\partial}{\partial z} \hat{\psi}_g^{(\ell)}(\tau, z)\big|_{z=0} \tag{4.16}$$

is a weight 2 modular form for the group $\Gamma_0(N_g)$.

For general values of ℓ, specifying the weight 2 form $F_g^{(\ell)}(\tau)$ is not sufficient to specify the whole vector-valued modular form $\hat{H}_g^{(\ell)}$ since we have evidently collapsed information in taking the particular combination (4.16). However, for $\ell \in \{2, 3\}$ we are in the privileged situation that specifying the weight 2 form $F_g^{(\ell)}(\tau)$ completely specifies all the components of $H_g^{(\ell)}$, as will be explained in more detail in the following section. For $\ell > 3$ we need more weight 2 forms, and we will also consider

$$F_g^{(\ell),2}(\tau) = \sum_{r=1}^{\ell-1} (-1)^{r+1} \hat{H}_{g,r}^{(\ell)}(\tau) S_{\ell-r}^{(\ell)}(\tau). \tag{4.17}$$

In the next section we give our concrete proposals for the McKay–Thompson series $H_g^{(\ell)}$ for all but a few of the conjugacy classes $[g]$ arising. We give closed expressions for all the $H_g^{(\ell)}$ in case $\ell \in \{2,3,4,5\}$ and we partially determine the $H_g^{(\ell)}$ for $\ell = \{7,13\}$. Although we do not offer analytic expressions for all the $H_g^{(\ell)}$ with $\ell = 7$ or $\ell = 13$ we have predictions for the low degree terms in the Fourier developments of all the McKay–Thompson series at all lambencies $\ell \in \Lambda$ and these are detailed in the tables of §C.

4.2 Lambency Two

$[g]$	N_g	$F_g^{(2)}(\tau)$
$1A$	1	0
$2A$	2	$-16\Lambda_2$
$2B$	4	$24\Lambda_2 - 8\Lambda_4 = -2\eta(\tau)^8/\eta(2\tau)^4$
$3A$	3	$-6\Lambda_3$
$3B$	9	$-2\eta(\tau)^6/\eta(3\tau)^2$
$4A$	8	$-4\Lambda_2 + 6\Lambda_4 - 2\Lambda_8 = -2\eta(2\tau)^8/\eta(4\tau)^4$
$4B$	4	$4(\Lambda_2 - \Lambda_4)$
$4C$	16	$-2\eta(\tau)^4\eta(2\tau)^2/\eta(4\tau)^2$
$5A$	5	$-2\Lambda_5$
$6A$	6	$2(\Lambda_2 + \Lambda_3 - \Lambda_6)$
$6B$	36	$-2\eta(\tau)^2\eta(2\tau)^2\eta(3\tau)^2/\eta(6\tau)^2$
$7AB$	7	$-\Lambda_7$
$8A$	8	$\Lambda_4 - \Lambda_8$
$10A$	20	$-2\eta(\tau)^3\eta(2\tau)\eta(5\tau)/\eta(10\tau)$
$11A$	11	$\frac{2}{5}(-\Lambda_{11} + 11f_{11})$
$12A$	24	$-2\eta(\tau)^3\eta(4\tau)^2\eta(6\tau)^3/\eta(2\tau)\eta(3\tau)\eta(12\tau)^2$
$12B$	144	$-2\eta(\tau)^4\eta(4\tau)\eta(6\tau)/\eta(2\tau)\eta(12\tau)$
$14AB$	14	$\frac{1}{3}(\Lambda_2 + \Lambda_7 - \Lambda_{14} + 14f_{14})$
$15AB$	15	$\frac{1}{4}(\Lambda_3 + \Lambda_5 - \Lambda_{15} + 15f_{15})$
$21AB$	63	$\frac{1}{3}(-7\eta(\tau)^3\eta(7\tau)^3/\eta(3\tau)\eta(21\tau) + \eta(\tau)^6/\eta(3\tau)^2)$
$23AB$	23	$\frac{1}{11}(-\Lambda_{23} + 23f_{23,a} + 69f_{23,b})$

Table 3: The list of weight 2 modular forms $F_g^{(2)}(\tau)$ for $\Gamma_0(N_g)$.

When $\ell = 2$ the vector-valued mock modular form $H_g^{(2)}$ has only one component $H_{g,1}^{(2)}$ and our conjecture relating the $H_g^{(2)}$ and the group $G^{(2)}$ is nothing but the conjecture relating (scalar-valued) mock modular forms and the largest Mathieu group M_{24} that has been investigated recently [15, 19, 24, 20, 21, 22, 108, 109]. See also [41, 110] for reviews and [111, 112] for related discussions. Explicit expressions for the McKay–Thompson series arising from the M_{24}-module that is conjectured to underlie this connection have been proposed in [19, 20, 21, 22]. As mentioned before, one convenient way to express them is via a set of weight 2 modular forms $F_g^{(2)}(\tau)$. In this case (4.15-4.16) simply reduces to

$$H_{g,1}^{(2)}(\tau) = \frac{\chi_g^{(2)}}{24} H_1^{(2)}(\tau) + \frac{F_g^{(2)}(\tau)}{\eta(\tau)^3} \ , \tag{4.18}$$

where we have used $\chi^{(2)} = 24$ and $S_1^{(2)}(\tau) = \eta(\tau)^3$. For later use and for the sake of completeness we collect the explicit expressions for $F_g^{(2)}(\tau)$ for all conjugacy classes $[g] \subset M_{24}$ in Table 3. They are given in terms of eta quotients and standard generators of the weight 2 modular forms of level N. Among the latter are those denoted here by $\Lambda_N(\tau)$ and $f_N(\tau)$ and given explicitly in Appendix A.

4.3 Lambency Three

We would like to specify the two components $H_{g,1}^{(3)}(\tau)$ and $H_{g,2}^{(3)}(\tau)$ of the vector-valued mock modular form $\big(H_{g,r}^{(3)}(\tau)\big)$ which we propose to be the McKay–Thompson series arising from the $G^{(3)}$-module $K^{(3)}$. As mentioned earlier, to specify $H_{g,1}^{(3)}(\tau)$ and $H_{g,2}^{(3)}(\tau)$ it is sufficient to specify the weight 2 forms defined in (4.16). To see this, recall that to any given conjugacy class $[g]$ we can associate a conjugacy class $[zg]$ such that (4.13) holds. From this we obtain

$$\begin{aligned}
H_{g,1}^{(3)}(\tau) &= \frac{\bar{\chi}_g^{(3)}}{\chi^{(3)}} H_1^{(3)}(\tau) + \frac{1}{2}\frac{\eta(4\tau)^2}{\eta(2\tau)^5}\big(F_g^{(3)}(\tau) + F_{zg}^{(3)}(\tau)\big),\\
H_{g,2}^{(3)}(\tau) &= \frac{\chi_g^{(3)}}{\chi^{(3)}} H_2^{(3)}(\tau) + \frac{1}{4}\frac{\eta(2\tau)}{\eta(\tau)^2\eta(4\tau)^2}\big(F_g^{(3)}(\tau) - F_{zg}^{(3)}(\tau)\big),
\end{aligned} \tag{4.19}$$

where we have used the eta quotient expressions

$$S_1^{(3)}(\tau) = \frac{\eta(2\tau)^5}{\eta(4\tau)^2}, \quad S_2^{(3)}(\tau) = 2\frac{\eta(\tau)^2\eta(4\tau)^2}{\eta(2\tau)}, \tag{4.20}$$

for the components of the unary theta series at $\ell = 3$.

The explicit expressions for $F_g^{(3)}(\tau)$ are listed in Table 4.

We also note that for the classes $3B$ and $6B$ we also have the following alternative expressions

$[g]$	N_g	$F_g^{(3)}(\tau)$
1A	1	0
2A	4	0
4A	16	$-2\eta(\tau)^4\eta(2\tau)^2/\eta(4\tau)^2$
2B	2	$-16\Lambda_2$
2C	4	$16(\Lambda_2 - \Lambda_4/3)$
3A	3	$-6\Lambda_3$
6A	12	$-9\Lambda_2 - 2\Lambda_3 + 3\Lambda_4 + 3\Lambda_6 - \Lambda_{12}$
3B	9	$8\Lambda_3 - 2\Lambda_9 + 2\,\eta^6(\tau)/\eta^2(3\tau)$
6B	36	$-2\eta(\tau)^5\eta(3\tau)/\eta(2\tau)\eta(6\tau)$
4B	8	$-2\eta(2\tau)^8/\eta(4\tau)^4$
4C	4	$-8\Lambda_4/3$
5A	5	$-2\Lambda_5$
10A	20	$\sum_{d\vert 20} c_{10A}(d)\Lambda_d + \frac{20}{3}f_{20}$
12A	144	$-2\eta(\tau)\eta(2\tau)^5\eta(3\tau)/\eta(4\tau)^2\eta(6\tau)$
6C	6	$2(\Lambda_2 + \Lambda_3 - \Lambda_6)$
6D	12	$-5\Lambda_2 - 2\Lambda_3 + \frac{5}{3}\Lambda_4 + 3\Lambda_6 - \Lambda_{12}$
8AB	32	$-2\eta(2\tau)^4\eta(4\tau)^2/\eta(8\tau)^2$
8CD	8	$-2\Lambda_2 + \frac{5}{3}\Lambda_4 - \Lambda_8$
20AB	80	$-2\eta(2\tau)^7\eta(5\tau)/\eta(\tau)\eta(4\tau)^2\eta(10\tau)$
11AB	11	$-\frac{2}{5}\Lambda_{11} - \frac{33}{5}f_{11}$
22AB	44	$\sum_{d\vert 44} c_{22AB}(d)\Lambda_d(\tau) - \frac{11}{5}\sum_{d\vert 4} c'_{22AB}(d)f_{11}(d\tau) + \frac{22}{3}f_{44}(\tau)$

$c_{10A}(d) = -5, \frac{5}{3}, -\frac{2}{3}, 1, -\frac{1}{3}$ for $d = 2, 4, 5, 10, 20$
$c_{22AB}(d) = -\frac{11}{5}, \frac{11}{15}, -\frac{2}{15}, \frac{1}{5}, -\frac{1}{15}$ for $d = 2, 4, 11, 22, 44$
$c'_{22AB}(d) = 1, 4, 8$ for $d = 1, 2, 4$

Table 4: The list of weight 2 modular forms $F_g^{(3)}(\tau)$ for $\Gamma_0(N_g)$.

for the McKay–Thompson series in terms of eta quotients:

$$H^{(3)}_{3B,1}(\tau) = H^{(3)}_{6B,1}(\tau) = -2\frac{\eta(\tau)\eta(6\tau)^5}{\eta(3\tau)^3\eta(12\tau)^2}, \quad H^{(3)}_{3B,2}(\tau) = -H^{(3)}_{6B,2}(\tau) = -4\frac{\eta(\tau)\eta(12\tau)^2}{\eta(3\tau)\eta(6\tau)}. \quad (4.21)$$

Coincidences with Ramanujan's mock theta functions will be discussed (4.7).

4.4 Lambency Four

The McKay–Thompson series for lambency 4 display an interesting relation with those for lambency 2. To see this, notice the following relation among the theta functions

$$S^{(4)}_1(2\tau) - S^{(4)}_3(2\tau) = S^{(2)}_1(\tau). \quad (4.22)$$

Given this relation it is natural to consider the function

$$H^{(4)}_{g,*}(\tau) := H^{(4)}_{g,1}(\tau) - H^{(4)}_{g,3}(\tau) \quad (4.23)$$

for each conjugacy classe $[g]$ of $G^{(4)}$. Note that $H^{(4)}_{g,1}(\tau)$ and $H^{(4)}_{g,3}(\tau)$ can be reconstructed from $H^{(4)}_{g,*}(\tau)$ since they are q-series of the form $q^{-1/16}$ times a series of even or odd powers of $q^{1/2}$, respectively. Explicitly, we have

$$\begin{aligned} H^{(4)}_{g,1}(\tau) &= \tfrac{1}{2}\big(H^{(4)}_{g,*}(\tau) + e(\tfrac{1}{16})H^{(4)}_{g,*}(\tau+1)\big),\\ H^{(4)}_{g,3}(\tau) &= \tfrac{1}{2}\big(-H^{(4)}_{g,*}(\tau) + e(\tfrac{1}{16})H^{(4)}_{g,*}(\tau+1)\big). \end{aligned} \quad (4.24)$$

In order to obtain an expression for $H^{(4)}_{g,*}(\tau)$ we rely on the following two observations. First, recall in §3.4 we have observed a relation between the Frame shapes of $g \in G^{(4)}$ and $g' \in G^{(2)}$. It turns out that for a pair of group elements $g \in G^{(4)}$ and $g' \in G^{(2)}$ related in the way described in Proposition 3.4 their McKay–Thompson series $H^{(4)}_{g}(2\tau)$ and $H^{(2)}_{g'}(\tau)$ are also related in a simple way. As examples of this we have

$$\begin{aligned}
H^{(4)}_{1A,*}(\tau) &= H^{(4)}_{2A,*}(\tau) = H^{(2)}_{2A}(\tau/2)\\
H^{(4)}_{2B,*}(\tau) &= H^{(2)}_{4A}(\tau/2)\\
H^{(4)}_{2C,*}(\tau) &= H^{(2)}_{4B}(\tau/2)\\
H^{(4)}_{3A,*}(\tau) &= H^{(4)}_{6A,*}(\tau) = H^{(2)}_{6A}(\tau/2)\\
H^{(4)}_{4C,*}(\tau) &= H^{(2)}_{8A}(\tau/2)\\
H^{(4)}_{6BC,*}(\tau) &= H^{(2)}_{12A}(\tau/2)\\
H^{(4)}_{7AB,*}(\tau) &= H^{(4)}_{14AB,*}(\tau) = H^{(2)}_{14AB}(\tau/2).
\end{aligned} \tag{4.25}$$

This leaves us just the classes $4A$, $4B$, and $8A$ that are not related to any element of $G^{(2)} \simeq M_{24}$ in the way described in Proposition 3.4. All of these classes have $\chi^{(4)}_g = \bar{\chi}^{(4)}_g = 0$. A second observation is that all the $H^{(3)}_{g,r}(\tau)$ for those classes $[g] \subset G^{(3)}$ with $\chi^{(3)}_g = \bar{\chi}^{(3)}_g = 0$ have an expression in terms of eta quotients according to Table 4, and so do the $H^{(2)}_g(\tau)$ for those classes $[g] \subset G^{(2)}$ with $\chi^{(2)}_g = 0$. This is consistent with our expectation that the shadow of the vector-valued mock modular form $\big(H^{(\ell)}_{g,r}(\tau)\big)$ is given by $\big(\chi^{(\ell)}_{g,r} S^{(\ell)}_r(\tau)\big)$, and hence $\big(H^{(\ell)}_{g,r}(\tau)\big)$ is nothing but a vector-valued modular form in the usual sense when $\chi^{(\ell)}_g = \bar{\chi}^{(\ell)}_g = 0$. Given this it is natural to ask whether we can find similar eta quotient expressions for $H^{(4)}_{g,*}(\tau)$ with $\chi^{(\ell)}_g = \bar{\chi}^{(\ell)}_g = 0$ when $\ell > 3$. We find

$$\begin{aligned}
H^{(4)}_{4A,*}(\tau) &= -2\frac{\eta(\tau/2)\eta(\tau)^2}{\eta(2\tau)^2},\\
H^{(4)}_{4B,*}(\tau) &= -2\frac{\eta(\tau/2)\eta(\tau)^4}{\eta(\tau)^2\eta(4\tau)^2},\\
H^{(4)}_{8A,*}(\tau) &= -2\frac{\eta(\tau)^3}{\eta(\tau/2)\eta(4\tau)}.
\end{aligned} \tag{4.26}$$

Together with (4.24) and Table 3, the above equations completely specify $H^{(4)}_{g,1}(\tau)$ and $H^{(4)}_{g,3}(\tau)$ for all conjugacy classes $[g]$ of $G^{(4)}$. We are left to determine the second components $H^{(4)}_{g,2}(\tau)$. To start with, we have $H^{(4)}_2(\tau) = H^{(4)}_{1A,2}(\tau) = -H^{(4)}_{2A,2}(\tau)$ given in terms of the decomposition of the weight 0 Jacobi form as explained in §2.5. To determine the rest, notice that (4.13) and (4.16) implies that

$$S^{(4)}_2(\tau)\left(H^{(4)}_{g,2}(\tau) - \frac{\chi^{(4)}_{g,2}}{\chi^{(4)}}H^{(4)}_2(\tau)\right) \tag{4.27}$$

should be a weight 2 modular form. Employing this consideration we arrive at

$$\begin{aligned}
H^{(4)}_{3A,2}(\tau) &= -H^{(4)}_{6A,2}(\tau)\\
&= \frac{1}{4}H^{(4)}_2(\tau) + \frac{1}{2\eta(2\tau)^3}\Big(-3\Lambda_2(\tau) - 4\Lambda_3(\tau) + \Lambda_6(\tau)\Big),\\
H^{(4)}_{7AB,2}(\tau) &= -H^{(4)}_{14AB,2}(\tau)\\
&= \frac{1}{8}H^{(4)}_2(\tau) + \frac{1}{12\,\eta(2\tau)^3}\Big(-7\Lambda_2(\tau) - 4\Lambda_7(\tau) + \Lambda_{14}(\tau) + 28f_{14}(\tau)\Big),
\end{aligned} \tag{4.28}$$

where we have used $S^{(4)}_2(\tau) = 2\eta(2\tau)^3$ and the hypothesis that

$$H^{(4)}_{g,2}(\tau) = 0 \tag{4.29}$$

for all classes not in the set $\{1A, 2A, 3A, 6A, 7AB, 14AB\}$. This finishes our proposal for the McKay–Thompson series $\big(H^{(4)}_{g,r}\big)$ at $\ell = 4$. Coincidences between some of the $H^{(4)}_{g,r}$ and Ramanujan's mock theta functions will be discussed in §4.7.

4.5 Lambency Five

As mentioned before, for $\ell = 5$ it is no longer sufficient to specify the weight 2 forms $F^{(\ell)}_g(\tau)$ as defined in (4.16). In this case we also need to specify the weight 2 forms $F^{(\ell),2}_g(\tau)$ defined in (4.17).

With the data of $F^{(5)}_g(\tau)$ and $F^{(5),2}_g(\tau)$ we can determine the $H^{(5)}_{g,r}$ using the relations

$$H^{(5)}_{g,r}(\tau) = \hat{H}^{(5)}_{g,r}(\tau) + \frac{\chi^{(5)}_{g,r}}{6}H^{(5)}_r(\tau) \tag{4.30}$$

and

$$\begin{aligned}
\hat{H}^{(5)}_{g,1}(\tau)S^{(5)}_1(\tau) + \hat{H}^{(5)}_{g,3}(\tau)S^{(5)}_3(\tau) &= \tfrac{1}{2}\Big(F^{(5)}_g(\tau) + F^{(5)}_{zg}(\tau)\Big)\\
\hat{H}^{(5)}_{g,1}(\tau)S^{(5)}_4(\tau) + \hat{H}^{(5)}_{g,3}(\tau)S^{(5)}_2(\tau) &= \tfrac{1}{2}\Big(F^{(5),2}_g(\tau) + F^{(5),2}_{zg}(\tau)\Big)\\
\hat{H}^{(5)}_{g,2}(\tau)S^{(5)}_2(\tau) + \hat{H}^{(5)}_{g,4}(\tau)S^{(5)}_4(\tau) &= \tfrac{1}{2}\Big(F^{(5)}_g(\tau) - F^{(5)}_{zg}(\tau)\Big)\\
\hat{H}^{(5)}_{g,2}(\tau)S^{(5)}_3(\tau) + \hat{H}^{(5)}_{g,4}(\tau)S^{(5)}_1(\tau) &= \tfrac{1}{2}\Big(-F^{(5),2}_g(\tau) + F^{(5),2}_{zg}(\tau)\Big)
\end{aligned} \tag{4.31}$$

where g and zg again form a pair satisfying (4.13).

Moreover, notice that in $F^{(5),2}_g(\tau)$ the part of the sum involving even r has an expansion in $q^{1/4+k}$ for non-negative integers k, while the sum over odd r has an expansion in $q^{3/4+k}$. As

$[g]$	N_g	$F_g^{(5)}(\tau)$	$F_g^{(5),2}(\tau)$
1A	1	0	0
2A	4	0	0
2B	4	$16(\Lambda_2-\Lambda_4/3)$	$-\frac{8}{3}\eta(\tau)^8/\eta(\tau/2)^4$
2C	2	$-16\Lambda_2$	$e(\frac{1}{4})\,F_{2B}^{(5),2}(\tau+1)$
3A	9	$-2\eta^6(\tau)/\eta^2(3\tau)$	$-2\frac{\eta(\tau)^8\eta(3\tau/2)^2\eta(6\tau)^2}{\eta(\tau/2)^2\eta(2\tau)^2\eta(3\tau)^4}$
6A	36	$-2\,\eta(\tau)^2\eta(2\tau)^2\eta(3\tau)^2/\eta(6\tau)^2$	$2\,\eta(\tau/2)^2\eta(\tau)^2\eta(3\tau)^2/\eta(3\tau/2)^2$
4AB	16	$-2\eta(2\tau)^{14}/\eta(\tau)^4\eta(4\tau)^6$	$-16\eta(\tau)^2\eta(4\tau)^6/\eta(2\tau)^4$
4CD	8	$-8/3\Lambda_4(\tau)$	$-\frac{32}{3}\,\eta(2\tau)^2\eta(4\tau)^2/\eta(\tau)^2$
5A	5	$-2\Lambda_5$	$e(\frac{1}{4})\,F_{10A}^{(5),2}(\tau+1)$
10A	20	$\sum_{d\mid 20}c_{10A}(d)\Lambda_d-\frac{40}{3}f_{20}$	$\sum_{d\mid 20}c_{10A,2}(d)\Lambda_d(\tau/4)+\frac{10}{3}f_{20}(\tau/4)$
12AB	144	$-2\eta(\tau)^2\eta(2\tau)^2\eta(6\tau)^4/\eta(3\tau)^2\eta(12\tau)^2$	$-4\eta(\tau)^2\eta(2\tau)^2\eta(12\tau)^2/\eta(6\tau)^2$
$c_{10A}(d)=-5,\frac{5}{3},-\frac{2}{3},1,-\frac{1}{3}$ for $d=2,4,5,10,20$			
$c_{10A,2}(d)=-\frac{5}{4},\frac{5}{24},-\frac{1}{3},\frac{1}{4},-\frac{1}{24}$ for $d=2,4,5,10,20$			

Table 5: The list of weight 2 modular forms $F_g^{(5)}(\tau)$ on $\Gamma_0(N_g)$ and the other set of weight 2 modular forms $F_g^{(5),2}(\tau)$.

a result, it is sufficient to specify $F_g^{(\ell),2}(\tau)$ for one of the paired classes g and zg as they are related to each other by

$$F_{zg}^{(5),2}(\tau)=e(\tfrac{1}{4})\,F_g^{(\ell),2}(\tau+1)\ . \tag{4.32}$$

Using (4.30-4.32), the data recorded in Table 5 are sufficient to explicitly specify all the mock modular forms $H_g^{(5)}(\tau)$ for all $[g]\subset G^{(5)}$ at lambency 5.

4.6 Lambencies Seven and Thirteen

For $\ell=7$, apart from the $1A$ and $2A$ classes whose McKay-Thomson series have been given in terms of the weight 0 Jacobi form $Z^{(7)}$ in §2.5, there are five more classes $3AB$, $4A$, and $6AB$ whose McKay-Thomson series $H_g^{(7)}$ we would like to identify. We specify the weight 2 forms associated to these classes. Notice that these expressions are not sufficient to completely determine all the components $H_{g,r}^{(7)}$. Nevertheless, they provide strong evidence for the mock modular properties of the proposed McKay–Thompson series.

$$\begin{aligned}
F^{(7)}_{4A}(\tau) &= -2\frac{\eta(\tau)^4\eta(2\tau)^2}{\eta(4\tau)^2},\\
F^{(7),2}_{4A}(\tau) &= 4\frac{\eta(\tau)^6\eta(4\tau)^2}{\eta(2\tau)^4},\\
F^{(7)}_{3AB}(\tau) &= -6\Lambda_3(\tau),\\
F^{(7)}_{6AB}(\tau) &= -9\Lambda_2(\tau)-2\Lambda_3(\tau)+3\Lambda_4(\tau)+3\Lambda_6(\tau)-\Lambda_{12}(\tau),\\
F^{(7),2}_{6AB}(4\tau) &= -\frac{9}{4}\Lambda_2(\tau)-\Lambda_3(\tau)+\frac{3}{8}\Lambda_4(\tau)+\frac{3}{4}\Lambda_6(\tau)-\frac{1}{8}\Lambda_{12}(\tau).
\end{aligned}\tag{4.33}$$

Similarly, for lambency 13 we have

$$\begin{aligned}
F^{(13)}_{4AB}(\tau) &= -2\frac{\eta(2\tau)^{14}}{\eta(\tau)^4\eta(4\tau)^6},\\
F^{(13),2}_{4AB}(\tau) &= -16\frac{\eta(\tau)^2\eta(4\tau)^6}{\eta(2\tau)^4}.
\end{aligned}\tag{4.34}$$

4.7 Mock Theta Functions

As mentioned in §2.1 we observe that in many cases across different lambencies the components $H^{(\ell)}_{g,r}$ of the McKay–Thompson series coincide with known mock theta functions. In particular, we often encounter Ramanujan's mock theta functions, and always in such a way that the order is divisible by the lambency. In this section we will list these conjectural identities between $H^{(\ell)}_{g,r}$ and mock theta functions identified previously in the literature.

For $\ell = 2$ two of the functions $H^{(2)}_g(\tau)$ are related to Ramanujan's mock theta functions of orders 2 and 8 (cf. (2.7)) through

$$\begin{aligned}
H^{(2)}_{4B}(\tau) &= -2q^{-1/8}\mu(q),\\
H^{(2)}_{8A}(\tau) &= -2q^{-1/8}U_0(q).
\end{aligned}\tag{4.35}$$

For $\ell = 3$ we encounter the following order 3 mock theta functions of Ramanujan:

$$\begin{aligned}
H^{(3)}_{2B,1}(\tau) = H^{(3)}_{2C,1}(\tau) = H^{(3)}_{4C,1}(\tau) &= -2q^{-1/12}f(q^2),\\
H^{(3)}_{6C,1}(\tau) = H^{(3)}_{6D,1}(\tau) &= -2q^{-1/12}\chi(q^2),\\
H^{(3)}_{8C,1}(\tau) = H^{(3)}_{8D,1}(\tau) &= -2q^{-1/12}\phi(-q^2),\\
H^{(3)}_{2B,2}(\tau) = -H^{(3)}_{2C,2}(\tau) &= -4q^{2/3}\omega(-q),\\
H^{(3)}_{6C,2}(\tau) = -H^{(3)}_{6D,2}(\tau) &= 2q^{2/3}\rho(-q).
\end{aligned}\tag{4.36}$$

(Cf. (2.9).) The description of the shadow of $H_g^{(3)}$ is consistent with the fact that, among the seven order 3 mock theta functions of Ramanujan, $f(\tau)$, $\phi(\tau)$, $\psi(\tau)$ and $\chi(\tau)$ form a group with the same shadow $(S_1^{(3)}(\tau))$ while the other three $\omega(\tau)$, $\nu(\tau)$ and $\rho(\tau)$ form another group with another shadow $(S_2^{(3)}(\tau))$. Moreover, various relations among these order 3 mock theta functions can be obtained as consequences of the above identification.

For $\ell = 4$ we encounter the following order 8 mock theta functions

$$\begin{aligned} H^{(4)}_{2C,1}(\tau) &= q^{-\frac{1}{16}}\big(-2S_0(q)+4T_0(q)\big),\\ H^{(4)}_{2C,3}(\tau) &= q^{\frac{7}{16}}\big(2S_1(q)-4T_1(q)\big),\\ H^{(4)}_{4C,1}(\tau) &= -2\,q^{-\frac{1}{16}}S_0(q),\\ H^{(4)}_{4C,3}(\tau) &= 2\,q^{\frac{7}{16}}\,S_1(q). \end{aligned} \tag{4.37}$$

(Cf. (2.11).) Comparing with (2.7) we see that our proposal implies the identities

$$\begin{aligned} \mu(q) &= S_0(q^2)-2T_0(q^2)+q\big(S_1(q^2)-2T_1(q^2)\big)\\ &= U_0(q)-2U_1(q),\\ U_0(q) &= S_0(q^2)+q\,S_1(q^2),\\ U_1(\tau) &= T_0(q^2)+q\,T_1(q^2), \end{aligned} \tag{4.38}$$

between different mock theta functions of Ramanujan. See, for instance, [113] for a collection of such identities.

For $\ell = 5$ we encounter four of Ramanujan's order 10 mock theta functions:

$$\begin{aligned} H^{(5)}_{2BC,1}(\tau) &= H^{(5)}_{4CD,1}(\tau) = -2q^{-\frac{1}{20}}\,X(q^2),\\ H^{(5)}_{2BC,3}(\tau) &= H^{(5)}_{4CD,3}(\tau) = -2q^{-\frac{9}{20}}\,\chi_{10}(q^2),\\ H^{(5)}_{2C,2}(\tau) &= -H^{(5)}_{2B,2}(\tau) = 2q^{-\frac{1}{5}}\,\psi_{10}(-q),\\ H^{(5)}_{2C,4}(\tau) &= -H^{(5)}_{2B,4}(\tau) = -2q^{\frac{1}{5}}\,\phi_{10}(-q). \end{aligned} \tag{4.39}$$

(Cf. (2.10).)

4.8 Automorphy

In this section we discuss the automorphy of the proposed McKay–Thompson series $H_g^{(\ell)} = \big(H_{g,r}^{(\ell)}\big)$. As mentioned in §4.1, the function $H_g^{(\ell)}$ is a vector-valued mock modular form with shadow $\big(\chi_{g,r}S_r^{(\ell)}\big)$ for some $\Gamma_g \subset SL_2(\mathbb{Z})$ with a certain (matrix-valued) multiplier ν_g. In this subsection we will specify the group Γ_g and the multiplier ν_g. The multipliers we specify here can be verified explicitly using the data given in §§4.2-4.6 (except for the few conjugacy classes at $\ell = 7$ and $\ell = 13$ for which the McKay–Thompson series $H_g^{(\ell)}$ have not been completely determined).

We find that the automorphy of the vector-valued function $H_g^{(\ell)}$ is governed, in way that we shall describe presently, by the signed permutation representation of $G^{(\ell)}$ arising from the construction (as a subgroup of Oct_m for $m = 24/(\ell-1)$) given in §3.4. We use this representation to define the symbols $n_g|h_g$ which appear in the second row of each table 20-47, and also in the twisted Euler character tables 14-19, and we will explain below how to use these symbols to determine the multiplier system for each $H_g^{(\ell)}$. It will develop also that the twisted Euler character $g \mapsto \chi_g^{(\ell)}$ (cf. Tables 14-19) attached to the signed permutation representation of $G^{(\ell)}$ determines the shadow of $H_g^{(\ell)}$.

Recall from §3.4 that the signed permutation representation of $G^{(\ell)}$ naturally induces a permutation representation of the same degree, and this permutation representation factors through the quotient $\bar{G}^{(\ell)} = G^{(\ell)}/2$ of $G^{(\ell)}$ by its unique central subgroup of order 2 (except in case $\ell = 2$ when the signed and unsigned permutation representations coincide, and we have $G^{(2)} = \bar{G}^{(2)}$). Let $g \mapsto \bar{g}$ denote the natural map $G^{(\ell)} \to \bar{G}^{(\ell)}$ and observe that (for $\ell > 2$) if the unique central involution of $G^{(\ell)}$ belongs to the cyclic subgroup $\langle g \rangle$ generated by g then $o(g) = 2o(\bar{g})$ and otherwise $o(g) = o(\bar{g})$. We say that $g \in G^{(\ell)}$ is *split* over $\bar{G}^{(\ell)}$ in case $o(g) = o(\bar{g})$ and we call g *non-split* otherwise. (By this definition every element of $G^{(2)} = \bar{G}^{(2)}$ is split.)

Recall from §3.4 that $g \mapsto \Pi_g^{(\ell)}$ denotes the map attaching signed permutation Frame shapes to elements of $G^{(\ell)}$ and $g \mapsto \bar{\Pi}_g^{(\ell)}$ denotes the Frame shapes (actually cycle shapes) arising from the (unsigned) permutation representation (on $m = 24/(\ell-1)$ points). Taking a formal product of Frame shapes $\tilde{\Pi}_g^{(\ell)} = \Pi_g^{(\ell)} \bar{\Pi}_g^{(\ell)}$ (defined so that $j^{m_1} j^{m_2} = j^{m_1+m_2}$, &c.) we obtain the Frame shape of $g \in G^{(\ell)}$ regarded as a permutation of the $2m$ points $\{\pm e_i\}$ for $i \in \Omega^{(\ell)}$ (cf. §3.4). In particular, $\tilde{\Pi}_g$ is a cycle shape and none of the exponents appearing in $\tilde{\Pi}_g$ are negative. Given $g \in G^{(\ell)}$ and $\tilde{\Pi}_g = j_1^{m_1} \cdots j_k^{m_l}$ with $j_1 < \cdots < j_k$ and $m_i > 0$ define $N_g = j_1 j_k$. That is, set N_g to be the product of the shortest and longest cycle lengths appearing in a cycle decomposition for g regarded as a permutation on the $2m$ points $\{\pm e_i\}$. Now define the symbols $n_g|h_g$ by setting $n_g = o(\bar{g})$ for all $g \in G^{(\ell)}$ and all $\ell \in \Lambda$, and by setting $h_g = N_g/n_g$ for all $g \in G^{(\ell)}$ and $\ell \in \Lambda$ except when $\ell = 4$ and g is non-split in which case set $h_g = N_g/2n_g$. The symbols $n_g|h_g$ are specified in Tables 14-19, and also in Tables 20-47, in the rows labelled Γ_g. We omit the $|h_g$ when $h_g = 1$, so n_g is a shorthand for $n_g|1$ in these tables.

The significance of the value n_g is that it is the minimal positive integer n for which $H_g^{(\ell)}$ is a mock modular form (of weight 1/2) on $\Gamma_0(n)$, and the significance of h_g is that, as we shall see momentarily, it is the minimal positive integer h for which the multiplier for $H_g^{(\ell)}$ coincides with the conjugate multiplier for the (vector-valued) cusp form $S^{(\ell)}$ when restricted to $\Gamma_0(nh)$ (for $n = n_g$). Since $n_g h_g \leq N_g$ for all g the multiplier for $H_g^{(\ell)}$ coincides with the conjugate multiplier for $S^{(\ell)}$ when regarded as a mock modular form on $\Gamma_0(N_g)$ for all g. It is very curious that this coincidence of multipliers extends to the larger group $\Gamma_0(N_g/2)$ in the case that $\ell = 4$ and g is non-split (i.e. $o(g) = 2o(\bar{g})$).

Table 6: Admissible $v^{(\ell)}$

ℓ	2	3	4	5	7	13
$v^{(\ell)}$	1	5	3	7	1	7

Given a pair of positive integers (n, h) we define a matrix-valued function $\rho^{(\ell)}_{n|h}$ on $\Gamma_0(n)$ as follows. For each $\ell \in \Lambda$ let the integer $v^{(\ell)}$ be as specified in Table 6. When h divides n we set

$$\rho^{(\ell)}_{n|h}(\gamma) = \mathrm{e}\left(-v^{(\ell)}\frac{cd}{nh}\right)\mathrm{I}_{\ell-1} \tag{4.40}$$

where $\mathrm{I}_{\ell-1}$ denotes the $(\ell-1)\times(\ell-1)$ identity matrix. When h does not divide n and n is even we set

$$\rho^{(\ell)}_{n|h}(\gamma) = \mathrm{e}\left(-v^{(\ell)}\frac{cd}{nh}\frac{(n,h)}{n}\right)\mathrm{J}_{\ell-1}^{c(d+1)/n}\mathrm{K}_{\ell-1}^{c/n} \tag{4.41}$$

where (n, h) denotes the greatest common divisor of n and h, and $\mathrm{J}_{\ell-1}$ and $\mathrm{K}_{\ell-1}$ are the $(\ell-1)\times(\ell-1)$ matrices given by

$$\mathrm{J}_{\ell-1} = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 \\ 0 & -1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & (-1)^{\ell} \end{pmatrix}, \quad \mathrm{K}_{\ell-1} = \begin{pmatrix} 0 & \cdots & 0 & 0 & 1 \\ 0 & \cdots & 0 & 1 & 0 \\ 0 & \cdots & 1 & 0 & 0 \\ \vdots & .\cdot\cdot & \vdots & \vdots & \vdots \\ 1 & \cdots & 0 & 0 & 0 \end{pmatrix}, \tag{4.42}$$

and when h does not divide n and n is odd we set

$$\rho^{(\ell)}_{n|h}(\gamma) = \mathrm{e}\left(-v^{(\ell)}\frac{cd}{nh}\frac{n}{(n,h)}\right)\mathrm{J}_{\ell-1}^{c(d+1)/n}\mathrm{K}_{\ell-1}^{c/n}. \tag{4.43}$$

Now the multiplier system $\nu_g^{(\ell)}$ for the umbral mock modular form $H_g^{(\ell)}$ is the matrix-valued function on $\Gamma_0(n) = \Gamma_0(n_g)$ given simply by

$$\nu_g^{(\ell)} = \nu^{(\ell)}_{n|h} = \rho^{(\ell)}_{n|h}\overline{\sigma^{(\ell)}} \tag{4.44}$$

where $n = n_g$ and $h = h_g$ and $\sigma^{(\ell)} = (\sigma^{(\ell)}_{ij})$ denotes the (matrix-valued) multiplier system for the (vector-valued) theta series $S^{(\ell)}$ (cf. (2.26)) and satisfies

$$\sigma^{(\ell)}(\gamma)S^{(\ell)}(\gamma\tau)\mathrm{jac}(\gamma,\tau)^{3/4} = S^{(\ell)}(\tau) \tag{4.45}$$

for $\gamma \in \Gamma_0(1) = SL_2(\mathbb{Z})$ where $\mathrm{jac}(\gamma,\tau) = (c\tau+d)^{-2}$ in case γ has lower row (c,d).

Recall from §3.4 that the character of $G^{(\ell)}$ attached to its signed permutation representation is denoted $g \mapsto \chi^{(\ell)}_g$ in Tables 14-19 and that of the (unsigned) permutation representation is denoted $g \mapsto \bar{\chi}^{(\ell)}_g$. Define $\chi^{(\ell)}_{g,r}$ for $0 < r < \ell$ by setting $\chi^{(\ell)}_{g,r} = \chi^{(\ell)}_g$ in case r is even and $\chi^{(\ell)}_{g,r} = \bar{\chi}^{(\ell)}_g$ otherwise. Then the shadow of $H^{(\ell)}_g$ is the function $S^{(\ell)}_g = \left(S^{(\ell)}_{g,r}\right)$ with components related to those of $S^{(\ell)}$ by $S^{(\ell)}_{g,r} = \chi^{(\ell)}_{g,r}S^{(\ell)}_r$. In particular, $H^{(\ell)}_g$ is a vector-valued modular form of weight 1/2 for $\Gamma_0(n_g)$ when $\chi^{(\ell)}_g = \bar{\chi}^{(\ell)}_g = 0$.

To summarise, we claim that our proposed McKay–Thompson series $H^{(\ell)}_g$ are such that if we define $\hat{H}^{(\ell)}_g = \left(\hat{H}^{(\ell)}_{g,r}\right)$ by setting

$$\hat{H}^{(\ell)}_{g,r}(\tau) = H_{g,r}(\tau) - \frac{\chi^{(\ell)}_{g,r}}{\sqrt{2\ell}}\frac{1}{(4i)^{1/2}}\int_{-\bar{\tau}}^{i\infty}(z+\tau)^{-1/2}S^{(\ell)}_r(z)\mathrm{d}z \tag{4.46}$$

for $0 < r < \ell$ then $\hat{H}^{(\ell)}_g$ is invariant for the weight 1/2 action of $\Gamma_0(n)$ on $(\ell-1)$-vector-valued functions on $\mathbb{H}$ given by

$$\left(\hat{H}^{(\ell)}_g\Big|_{1/2,n|h}\gamma\right)(\tau) = \nu_{n|h}(\gamma)\hat{H}^{(\ell)}_g(\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{1/4} \tag{4.47}$$

where $n = n_g$ and $h = h_g$ and $\nu_{n|h}$ is defined by (4.44). This statement completely describes the (conjectured) automorphy of the mock modular forms $H^{(\ell)}_g$ (cf. §5.3).

5 Conjectures

We have described the umbral forms $Z^{(\ell)}$, $H^{(\ell)}$ and $\Phi^{(\ell)}$ in §2 and the umbral groups $G^{(\ell)}$ in §3 and we have introduced families $\{H^{(\ell)}_g \mid g \in G^{(\ell)}\}$ of vector-valued mock modular forms in §4. The discussions of those sections clearly demonstrate the distinguished nature of these objects, and we have mentioned some coincidences relating the groups $G^{(\ell)}$ and the forms $H^{(\ell)}_g$ directly. In this section we present, in a more systematic fashion, evidence that the relationship between the $G^{(\ell)}$ and the $H^{(\ell)}$ is more than coincidental. Our observations lead naturally to conjectures that we hope will serve as first steps in revealing the structural nature of the mechanism underlying umbral moonshine.

5.1 Modules

As was mentioned in §4, after comparison of the character tables (cf. §B.1) of the umbral groups $G^{(\ell)}$ with the Fourier coefficient tables (cf. §C) for the forms $H_g^{(\ell)}$ it becomes apparent that the low degree Fourier coefficients of $H^{(\ell)} = H_e^{(\ell)}$ may be interpreted as degrees of representations of $G^{(\ell)}$ in such a way that the corresponding coefficients of $H_g^{(\ell)}$ are recovered by substituting character values at g; we have tabulated evidence for this in the form of explicit combinations of irreducible representations in §D. This observation suggests the existence of bi-graded $G^{(\ell)}$-modules $K^{(\ell)} = \bigoplus K_{r,d}^{(\ell)}$ whose bi-graded dimensions are recovered via Fourier coefficients from the vector-valued mock modular forms $H^{(\ell)} = \left(H_r^{(\ell)}\right)$.

Conjecture 5.1. *We conjecture that for $\ell \in \Lambda = \{2,3,4,5,7,13\}$ there exist naturally defined $\mathbb{Z}\times\mathbb{Q}$-graded $G^{(\ell)}$-modules*

$$K^{(\ell)} = \bigoplus_{\substack{r\in\mathbb{Z}\\0<r<\ell}} K_r^{(\ell)} = \bigoplus_{\substack{r,k\in\mathbb{Z}\\0<r<\ell}} K_{r,k-r^2/4\ell}^{(\ell)} \tag{5.1}$$

such that the graded dimension of $K^{(\ell)}$ is related to the vector-valued mock modular form $H^{(\ell)} = \left(H_r^{(\ell)}\right)$ by

$$H_r^{(\ell)}(\tau) = -2\delta_{r,1}q^{-1/4\ell} + \sum_{\substack{k\in\mathbb{Z}\\r^2-4k\ell<0}} \dim\left(K_{r,k-r^2/4\ell}^{(\ell)}\right) q^{k-r^2/4\ell} \tag{5.2}$$

for $q = \mathrm{e}(\tau)$ and such that the vector-valued mock modular forms $H_g^{(\ell)} = \left(H_{g,r}^{(\ell)}\right)$ described in §4 (and partially in the tables of §C) are recovered from $K^{(\ell)}$ via graded trace functions according to

$$H_{g,r}^{(\ell)}(\tau) = -2\delta_{r,1}q^{-1/4\ell} + \sum_{\substack{k\in\mathbb{Z}\\r^2-4k\ell<0}} \mathrm{tr}_{K_{r,k-r^2/4\ell}^{(\ell)}}(g) q^{k-r^2/4\ell}. \tag{5.3}$$

Remark 5.2. Recall that a *superspace* is a $\mathbb{Z}/2\mathbb{Z}$-graded vector space and if $V = V_{\bar 0}\oplus V_{\bar 1}$ is such an object and $T : V \to V$ is a linear operator preserving the grading then the *supertrace* of T is given by $\mathrm{str}_V T = \mathrm{tr}_{V_{\bar 0}} T - \mathrm{tr}_{V_{\bar 1}} T$ where $\mathrm{tr}_W T$ denotes the usual trace of T on W. Since the coefficient of $q^{-1/4\ell}$ in $H_{g,1}^{(\ell)}$ is $c_{g,1}^{(\ell)}(-1/4\ell) = -2$ for all $g \in G^{(\ell)}$ for all ℓ it is natural to expect that this term may be interpreted as the supertrace of $g \in G^{(\ell)}$ on a trivial $G^{(\ell)}$-supermodule $K_{1,-1/4\ell}^{(\ell)}$ with vanishing even part and 2-dimensional odd part. Thus Conjecture 5.1 implies the existence of a $G^{(\ell)}$-supermodule $K^{(\ell)} = \bigoplus K_{r,d}^{(\ell)}$ such that $K_{r,d}^{(\ell)}$ is purely even or purely odd according as d is positive or negative, and such that $H^{(\ell)}_{g,r} = \sum_k \mathrm{str}_{K^{(\ell)}_{r,k-r^2/4\ell}}(g)q^{k-r^2/r\ell}$ for each $0 < r < \ell$ and $g \in G^{(\ell)}$.

Remark 5.3. For $\ell \in \Lambda$ and $0 < r, s < \ell$ we have that $r^2 \equiv s^2 \pmod{4\ell}$ implies $r = s$ so the first index r in $K^{(\ell)}_{r,d}$ can be deduced from d since it is the unique $0 < r < \ell$ such that $d + r^2/4\ell$ is an integer. Thus we may dispense with the first of the two gradings on the conjectural $G^{(\ell)}$-modules $K^{(\ell)}$ and regard them as $\mathbb{Q}$-graded $K^{(\ell)} = \bigoplus_d K^{(\ell)}_d$ by the rationals of the form $d = n - r^2/4\ell$ for $n \in \mathbb{Z}$ and $0 < r < \ell$ without introducing any ambiguity.

5.2 Moonshine

In the case of monstrous moonshine the McKay–Thompson series T_g for g in the monster group have the astonishing property that they all serve as generators for the function fields of their invariance groups (cf. [1]). In other words, if Γ_g is the subgroup of $PSL_2(\mathbb{R})$ consisting of the isometries $\gamma : \mathbb{H} \to \mathbb{H}$ such that $T_g(\gamma\tau) = T_g(\tau)$ for all $\tau \in \mathbb{H}$ then T_g induces an isomorphism from the compactification of $\Gamma_g\backslash\mathbb{H}$ to the Riemann sphere (being the one point compactification of $\mathbb{C}$). In particular, Γ_g is a genus zero subgroup of $PSL_2(\mathbb{R})$, and so this property is commonly referred to as the *genus zero property* of monstrous moonshine.

By now there are many methods extant for constructing graded vector spaces with algebraic structure whose graded dimensions are modular functions—suitable classes of vertex algebras, for example, serve this purpose (cf. [114, 115])—and so one can expect to obtain analogues of the McKay–Thompson series T_g by equipping such an algebraic structure with the action of a group. But there is no guarantee that such a procedure will result in functions that have the genus zero property of monstrous moonshine, and so it is this genus zero property that distinguishes the observations of McKay, Thompson, Conway and Norton regarding the Monster group from any number of more generic connections between finite groups and modular functions. In what follows we will propose a conjecture that may be regarded as the natural analogue of the Conway–Norton conjecture for umbral moonshine.

Suppose that $T : \mathbb{H} \to \mathbb{C}$ is a holomorphic function with invariance group $\Gamma < PSL_2(\mathbb{R})$ and a simple pole in $q = e(\tau)$ as $\tau \to i\infty$. Suppose also that Γ is commensurable with $PSL_2(\mathbb{Z})$ and that the *translation subgroup* Γ_∞, consisting of the elements of Γ with upper-triangular preimages in $SL_2(\mathbb{R})$, is generated by $\tau \mapsto \tau + 1$. It is shown in [25] that such a function T is a generator for the field of Γ-invariant functions on $\mathbb{H}$ if and only if $T(\tau)$ coincides with the weight

0 *Rademacher sum*

$$R_\Gamma(\tau) = \operatorname{Reg}\left(\sum_{\gamma\in\Gamma_\infty\backslash\Gamma} q^{-1}\big|_0\,\gamma\right) \tag{5.4}$$

attached to Γ. The sum here is over representatives for the cosets of Γ_∞ in Γ and $f \mapsto f|_0\gamma$ denotes the weight 0 action of γ on holomorphic functions (viz., $(f|_0\gamma)(\tau) = f(\gamma\tau)$). We write $\operatorname{Reg}(\cdot)$ to indicate a regularisation procedure first realised by Rademacher (for the case that $\Gamma = PSL_2(\mathbb{Z})$) in [26]. According then to the result of [25] the genus zero property of monstrous moonshine may be reformulated in the following way:

> For each element g in the monster group the McKay–Thompson series T_g satisfies $T_g = R_{\Gamma_g}$ when Γ_g is the invariance group of T_g.

This may be compared with the article [24] which considers the mock modular forms $H_g^{(2)}$ attached to the largest Mathieu group $G^{(2)} \simeq M_{24}$ via the observation of Eguchi–Ooguri–Tachikawa and applies some of the philosophy of [25] to the problem of finding a uniform construction for these functions. The solution developed in [24] is that the function $H_g^{(2)}$ coincides with the weight 1/2 Rademacher sum

$$R^{(2)}_{n|h}(\tau) = \operatorname{Reg}\left(\sum_{\gamma\in\Gamma_\infty\backslash\Gamma_0(n)} -2q^{-1/8}\Big|_{1/2,n|h}\,\gamma\right) \tag{5.5}$$

where $n = n_g$ and $h = h_g$ are integers determined by the defining permutation representation of M_{24} (cf. Table 14) and $f \mapsto f|_{1/2,n|h}\gamma$ denotes a certain weight 1/2 action of $\Gamma_0(n)$ determined by n and h. (We refer to [24] for full details.) By comparison with the previous paragraph we thus arrive at a direct analogue of the genus zero property of monstrous moonshine that holds for all the umbral forms with $\ell = 2$:

> For each element g in the largest Mathieu group the McKay–Thompson series $H_g^{(2)}$ satisfies $H_g^{(2)} = R^{(2)}_{n|h}$ when $n = n_g$ and $h = h_g$.

We conjecture that this genus zero property extends to all the functions of umbral moonshine.

Conjecture 5.4 (umbral moonshine)**.** *We conjecture that for each $\ell \in \Lambda$ and each $g \in G^{(\ell)}$ we* *have* $H_g^{(\ell)} = R_{n|h}^{(\ell)}$ *where* $n = n_g$ *and* $h = h_g$ *are as specified in* §B.2 *and*

$$R_{n|h}^{(\ell)} = \operatorname{Reg}\left(\sum_{\gamma\in\Gamma_\infty\backslash\Gamma_0(n)} \begin{pmatrix} -2q^{-1/4\ell} \\ 0 \\ \vdots \\ 0 \end{pmatrix}\Bigg|_{1/2,n|h} \gamma \right) \tag{5.6}$$

is a vector-valued generalisation of the Rademacher sum $R_{n|h}^{(2)}$ *adapted to the weight* $1/2$ *action of* $\Gamma_0(n)$ *on* $(\ell-1)$*-vector-valued functions on* $\mathbb{H}$ *that is defined in* (4.47).

5.3 Modularity

A beautiful feature of the umbral moonshine conjecture is that it implies the precise nature of the modularity of the Thompson series $H_g^{(\ell)}$. We record these implications explicitly as conjectures in this short section.

Conjecture 5.5. *We conjecture that the graded supertrace functions* (5.3) *for fixed* $\ell \in \Lambda$ *and* $g \in G^{(\ell)}$ *and varying* $0 < r < \ell$ *define the components of a vector-valued mock modular form* $H_g^{(\ell)}$ *of weight* $1/2$ *on* $\Gamma_0(n_g)$ *with shadow function* $S_g^{(\ell)} = (S_{g,r}^{(\ell)}) = (\chi_{g,r}^{(\ell)} S_r^{(\ell)})$ *where* $S^{(\ell)} = (S_r^{(\ell)})$ *is the vector-valued theta series described in* §2.3*, the* $\chi_{g,r}^{(\ell)}$ *are determined from the twisted Euler characters of* $G^{(\ell)}$ *(cf.* §B.2*) by* $\chi_{g,r}^{(\ell)} = \bar{\chi}_g^{(\ell)}$ *for* r *odd and* $\chi_{g,r}^{(\ell)} = \chi_g^{(\ell)}$ *for* r *even, and* n_g *denotes the order of the image of* $g \in G^{(\ell)}$ *in the factor group* $\bar{G}^{(\ell)}$ *(cf.* §3.1,3.4*).*

Recall from §4.8 that for $\ell \in \Lambda$ and a pair (n, h) of positive integers we have the matrix-valued function $\nu_{n|h}^{(\ell)}$ on $\Gamma_0(n)$ defined in (4.44). Recall also that we have attached a pair (n_g, h_g) to each $g \in G^{(\ell)}$ for each $\ell \in \Lambda$ in §4.8.

Conjecture 5.6. *We conjecture that the multiplier system of* $H_g^{(\ell)}$ *is given by* $\nu_{n|h}^{(\ell)}$ *when* $n = n_g$ *and* $h = h_g$ *for all* $g \in G^{(\ell)}$ *for all* $\ell \in \Lambda$*.*

5.4 Discriminants

One of the most striking features of umbral moonshine is the apparently intimate relation between the number fields on which the irreducible representations of $G^{(\ell)}$ are defined and the discriminants of the vector-valued mock modular form $H^{(\ell)}$. We discuss the evidence for this relation and formulate conjectures about it in this section.

First we observe that the discriminants of the components $H_r^{(\ell)}$ of the mock modular form $H^{(\ell)} = H_e^{(\ell)}$ determine some important properties of the representations of $G^{(\ell)}$, where we say that an integer D is a *discriminant of* $H^{(\ell)}$ if there exists a term $q^d = q^{-\frac{D}{4\ell}}$ with non-vanishing Fourier coefficient in at least one of the components. The following result can be verified explicitly using the tables in §§B,C.

Proposition 5.7. *Let $\ell \in \Lambda$. If $n > 1$ is an integer satisfying*

1. *there exists an element of $G^{(\ell)}$ of order n, and*
2. *there exists an integer λ that is co-prime to n such that $D = -n\lambda^2$ is a discriminant of $H^{(\ell)}$,*

then there exists at least one pair of irreducible representations ϱ and ϱ^* of $G^{(\ell)}$ and at least one element $g \in G^{(\ell)}$ such that $\mathrm{tr}_\varrho(g)$ is not rational but

$$\mathrm{tr}_\varrho(g), \mathrm{tr}_{\varrho^*}(g) \in \mathbb{Q}(\sqrt{-n}) \tag{5.7}$$

and n divides $o(g)$.

The finite list of integers n satisfying the two conditions of Proposition 5.7 is given in Table 7.

From now on we say that an irreducible representation ϱ of the umbral group $G^{(\ell)}$ is of *type* n if n is an integer satisfying the two conditions of Proposition 5.7 and the character values of ϱ generate the field $\mathbb{Q}(\sqrt{-n})$. Evidently, irreducible representations of type n come in pairs (ϱ, ϱ^*) with $\mathrm{tr}_{\varrho^*}(g)$ the complex conjugate of $\mathrm{tr}_\varrho(g)$ for all $g \in G^{(\ell)}$. The list of all irreducible representations of type n is given in Table 7. (See §B.1 for the character tables of the $G^{(\ell)}$ and our notation for irreducible representations.)

Recall that the *Frobenius–Schur indicator* of an irreducible ordinary representation of a finite group is 1, -1 or 0 according as the representation admits an invariant symmetric bilinear form, an invariant skew-symmetric bilinear form, or no invariant bilinear form, respectively. The representations admitting no invariant bilinear form are precisely those whose character values are not all real. We can now state the next observation.

Proposition 5.8. *For each $\ell \in \Lambda$ an irreducible representation ϱ of $G^{(\ell)}$ has Frobenius–Schur indicator* 0 *if and only if it is of type n for some n.*

The *Schur index* of an irreducible representation ϱ of a finite group G is the smallest positive integer s such that there exists a degree s extension k of the field generated by the character values $\mathrm{tr}_\varrho(g)$ for $g \in G$ such that ϱ can be realised over k. Inspired by Proposition 5.8 we make the following conjecture.

Conjecture 5.9. *If ϱ is an irreducible representation of $G^{(\ell)}$ of type n then the Schur index of ϱ is equal to* 1*.*

In other words, we conjecture that the irreducible $G^{(\ell)}$-representations of type n can be realised over $\mathbb{Q}(\sqrt{-n})$. For $\ell = 2$ this speculation is in fact a theorem, since it is known [116] that the Schur indices for M_{24} are always 1. For $\ell = 3$ it is also known [116] that the Schur indices for $\bar{G}^{(3)} = M_{12}$ are also always 1. Moreover, the representations of $G^{(3)} \simeq 2.\bar{G}^{(3)}$ with characters χ_{16} and χ_{17} in the notation of Table 9 have been constructed explicitly over $\mathbb{Q}(\sqrt{-2})$ in [117]. Finally, Proposition 5.8 constitutes a non-trivial consistency check for Conjecture 5.9 since the Schur index is at least 2 for a representation with Frobenius–Schur indicator equal to -1.

Table 7: The irreducible representations of type n.

Armed with the preceding discussion we are now ready to state our main observation for the discriminant property of umbral moonshine. For the purpose of stating this we temporarily write $K^{(\ell)}_{r,d}$ for the ordinary representation of $G^{(\ell)}$ with character $g \mapsto c^{(\ell)}_{g,r}(d)$ where the coefficients $c^{(\ell)}_{g,r}(d)$ are assumed to be those given in §C.

Proposition 5.10. *Let n be one of the integers in Table 7 and let λ_n be the smallest positive integer such that $D = -n\lambda_n^2$ is a discriminant of $H^{(\ell)}$. Then $K^{(\ell)}_{r,-D/4\ell} = \varrho_n \oplus \varrho_n^*$ where ϱ_n and ϱ_n^* are dual irreducible representations of type n. Conversely, if ϱ is an irreducible representation of type n and $-D$ is the smallest positive integer such that $K^{(\ell)}_{r,-D/4\ell}$ has ϱ as an irreducible constituent then there exists an integer λ such that $D = -n\lambda^2$.*

Extending this we make the following conjecture.

Conjecture 5.11. *If D is a discriminant of $H^{(\ell)}$ which satisfies $D = -n\lambda^2$ for some integer λ then the representation $K^{(\ell)}_{r,-D/4\ell}$ has at least one dual pair of irreducible representations of type n arising as irreducible constituents.*

We conclude this section with conjectures arising from the observation (cf. §D) that the conjectural $G^{(\ell)}$-module $K^{(\ell)}_{r,d}$ is typically isomorphic to several copies of a single representation. Say a G-module V is a *doublet* if it is isomorphic to the direct sum of two copies of a single representation of G.

Conjecture 5.12. *For $\ell \in \Lambda = \{2,3,4,5,7,13\}$ the representation $K^{(\ell)}_{r,-D/4\ell}$ is a doublet if and only if $D \neq -n\lambda^2$ for any integer λ for any n satisfying the conditions of Proposition 5.7.*

To see some evidence for Conjecture 5.12 one can inspect the proposed decompositions of the representations $K^{(\ell)}_{r,d}$ in the tables in §D for the following discriminants:

- $-D = 7, 15, 23, 63, 135, 175, 207$ for $\ell = 2$,
- $-D = 8, 11, 20, 32, 44, 80$ for $\ell = 3$,
- $-D = 7, 12, 28, 63, 108$ for $\ell = 4$,
- $-D = 4, 16, 64, 144, 196$ for $\ell = 5$,
- $-D = 3\lambda^2$, $\lambda = 1, \ldots, 9$, $\lambda \neq 7$ for $\ell = 7$,
- $-D = 4\lambda^2$, $\lambda = 1, \ldots, 11$ for $\ell = 13$.

5.5 Geometry and Physics

Beyond the conjectures already mentioned above several interesting and important questions remain regarding the structural nature of umbral moonshine. In the case that $\ell = 2$ there are strong indications that a deep relationship to $K3$ surfaces—extending in some way the relation [118, 119] between finite groups of $K3$ surface symplectomorphisms and subgroups of M_{23}—is responsible for the relationship between $G^{(2)} \simeq M_{24}$ and $H^{(2)}$. One such indication is the fact that the Jacobi form $Z^{(2)}$, from which $H^{(2)}$ may be obtained by decomposing with respect to superconformal characters, coincides with the elliptic genus of a(ny) complex $K3$ surface. It is natural then to ask if there are analogous geometric interpretations for the remaining extremal Jacobi forms $Z^{(\ell)}$ for $\ell \in \Lambda$, and a positive answer to this question will be a first step in determining the geometric significance of the umbral groups $G^{(\ell)}$ and the attached mock modular forms $H^{(\ell)}_g$.

In a series of papers [120, 121, 88, 87, 89] Gritsenko–Nikulin develop applications of Siegel modular forms to mirror symmetry for $K3$ surfaces (cf. [122]). Many of the Siegel forms arising are realised as additive or exponential lifts of (weak) Jacobi forms, and amongst many examples the exponential lifts $\Phi^{(\ell)}$ of the particular forms $Z^{(\ell)}$ for $\ell \in \{2,3,4,5\} \subset \Lambda$ appear in connection with explicitly defined families of lattice polarised $K3$ surfaces in [87]. It is natural to ask if there is an analogous relationship between the umbral $Z^{(\ell)}$ and suitably defined mirror families of $K3$ surfaces for the remaining ℓ in Λ.

As mentioned in the introduction, monstrous moonshine involves aspects of conformal field theory and string theory and there are several hints that umbral moonshine will also play a role in string theory. The most obvious hint at $\ell = 2$ is through the fact mentioned above that the weak Jacobi form $Z^{(2)}$ coincides with the elliptic genus of a $K3$ surface and the fact that $K3$ surfaces play a prominent role in the study of superstring compactification. The Siegel form $\Phi^{(2)} = (\Delta_5)^2$ which is the multiplicative lift of the weak Jacobi form $Z^{(2)}$ also plays a distinguished role in type II string theory on $K3 \times E$ where E is an elliptic curve and $1/\Phi^{(2)}$ occurs as the generating function which counts the number of 1/4 BPS dyon states [123]. BPS states in a supersymmetric theory are states that are annihilated by some of the supercharges of the theory; the 1/4 BPS states of interest here are annihilated by 4 of the 16 supercharges of a theory with $N = 4$ supersymmetry in four spacetime dimensions and are termed *dyons* because they necessarily carry both electric and magnetic charges. The relation between the zeros of $\Phi^{(2)}$ and the wall-crossing phenomenon in this theory has been studied in [124, 125, 126, 127] and this relation leads to a connection between the counting of BPS black hole states in string theory and mock modular forms [45]. For a pedagogical review of this material see [128, 38].

There are several hints that umbral moonshine for $\ell > 2$ will also play a role in string theory. The first of these occurs in the study of $N = 2$ dual pairs of string theories [129, 130]. An $N = 2$ dual pair consists of a compactification of the heterotic string on a product of a $K3$ surface with an elliptic curve E with a specific choice of $E_8 \times E_8$ gauge bundle on $K3 \times E$ and a conjectured dual description of this model in terms of IIA string theory on a Calabi–Yau threefold X which admits a $K3$ fibration. The low-energy description of such theories involves a vector-multiplet moduli space which is a special Kähler manifold of the form

$$\mathcal{M}_{vm}^{s+2,2} = \frac{SU(1,1)}{U(1)} \times \mathcal{N}^{s+2,2} \tag{5.8}$$

where $\mathcal{N}^{s+2,2}$ is the quotient $\Gamma\backslash\mathcal{H}^{s+1,1}$ of the generalised upper half-plane

$$\mathcal{H}^{s+1,1} = O(s+2,2;\mathbb{R})/(O(s+2) \times O(2)) \tag{5.9}$$

by an arithmetic subgroup Γ in $SO(s+2,2;\mathbb{R})$, with Γ depending on the specific model in question. One-loop string computations in the heterotic string lead to automorphic forms on $\mathcal{N}^{s+2,2}$ via a generalised theta lift constructed in [131, 132], see [133] for a review. In models with $s = 1$ this leads to automorphic forms on $\Gamma\backslash O(3,2;\mathbb{R})/(O(3) \times O(2))$, that is to Siegel modular forms on the genus 2 Siegel upper half-space $\mathbb{H}_2 \cong \mathcal{H}^{2,1}$.

A particular example of such an $N = 2$ dual pair was studied in [134, 135] with $s = 1$ and involving a dual description in terms of Type II string theory on a Calabi–Yau 3-fold with Hodge numbers $(h^{1,1}, h^{2,1}) = (4, 148)$. In the heterotic description the arithmetic subgroup which appears is the paramodular group Γ_2, the Siegel modular form which occurs is the exponential lift of $Z^{(3)}$ described in §2.6 and the Calabi–Yau 3-fold is also elliptically fibered and the elliptic fiber is of E_7 type. We thus see many of the ingredients of $\ell = 3$ umbral moonshine appearing in the context of a specific dual pair of string theories with $N = 2$ spacetime supersymmetry. It will be very interesting to investigate whether other aspects of $\ell = 3$ umbral moonshine can be realized in these models and whether $N = 2$ dual pairs exist which exhibit elements of umbral moonshine for $\ell > 3$.

A second way that elements of umbral moonshine for $\ell > 2$ are likely to appear in string theory involves a generalisation of the generating function discussed above that counts 1/4 BPS states. Type II string theory on $K3 \times E$ preserves $N = 4$ spacetime supersymmetry. There exist orbifold versions of this model that also preserve $N = 4$ spacetime supersymmetry that are known in the physics literature as CHL models. To construct such a model one chooses a $K3$ surface with a $\mathbb{Z}/m\mathbb{Z}$ hyper-Kähler automorphism and constructs the orbifold theory $(K3 \times E)/(\mathbb{Z}/m\mathbb{Z})$ where $\mathbb{Z}/m\mathbb{Z}$ is a freely acting symmetry realised as the product of a hyper-Kähler automorphism of the $K3$ surface and an order m translation along E. For $m = 2, 3, 4$ it is possible to find $K3$ surfaces with $(\mathbb{Z}/m\mathbb{Z}) \times (\mathbb{Z}/m\mathbb{Z})$ symmetry, and in this case one can construct a CHL model that utilises the first $\mathbb{Z}/m\mathbb{Z}$ factor in the orbifold construction and has the second $\mathbb{Z}/m\mathbb{Z}$ factor acting as a symmetry which preserves the holomorphic 3-form of the Calabi–Yau space $(K3 \times E)/(\mathbb{Z}/m\mathbb{Z})$. It was proposed in [136] that the generating function which counts 1/4 BPS states weighted by an element of $\mathbb{Z}/m\mathbb{Z}$ is the reciprocal of the Siegel form $\Phi^{(m+1)}$ for $m \in \{2, 3, 4\}$. In both this construction and in the study of $N = 2$ dual pairs the appearance of some of the umbral Siegel forms $\Phi^{(\ell)}$ can be anticipated, although many details remain to be worked out. The action of the umbral groups $G^{(\ell)}$ remains more elusive, and deeper insight into possible connections between string theory and umbral moonshine will undoubtedly require progress in understanding the actions of these groups in terms of their action on BPS states.

We plan to elaborate further on the topics mentioned above in future work.

Acknowledgements

We thank Chris Cummins, Atish Dabholkar, Noam Elkies, Igor Frenkel, George Glauberman, Ian Grojnowski, Kobi Kremnizer, Anthony Licata, Greg Moore, Sameer Murthy, Ken Ono, Cumrun Vafa, Erik Verlinde, Edward Witten, Shing-Tung Yau and Don Zagier for helpful comments and discussions. We thank Noam Elkies and Ken Ono in particular for communication regarding the non-vanishing of critical central values for modular L-functions.

We are especially grateful to Don Zagier for showing us his computation of the first few Fourier coefficients of the functions (that we have here denoted) $H^{(\ell)}$ for $\ell \in \{2,3,4,5,7\}$ at the "Workshop on Mathieu Moonshine" held in July 2011 at the Swiss Federal Institute of Technology (ETH), Zürich. This event was an important catalyst for precipitating the idea that there could be a family of groups attached to a distinguished family of vector-valued modular forms, in a way that generalises the connection between M_{24} and the (scalar-valued) mock modular form $H^{(2)}$. We are also grateful to Kazuhiro Hikami for his talk at the ETH meeting on character decompositions of elliptic genera, and for kindly sharing his slides from that presentation. The analysis described therein proved useful for us in developing a computational approach to approximate Fourier coefficients of the $H^{(\ell)}$ and this furnished an important source of experimental evidence to guide our umbral explorations. We warmly thank the organisers of the ETH meeting for making these exchanges possible and for providing an excellent workshop experience more generally.

The research of MC is partially supported by the NSF grant FRG 0854971. The work of JH was supported by the NSF grant 0855039, the hospitality of the Aspen Center for Physics, the LPTHE of the Université Pierre et Marie Curie, and the Isaac Newton Institute for Mathematical Sciences. We also thank George Armhold for instruction on the efficient implementation of Pari in OS X, and Jia-Chen Fu for the provision of computational resources at a crucial stage in our investigations.

We are grateful to George Glauberman, Sander Mack-Crane, and the referee, for pointing out errors in an earlier draft. We are grateful to the referee also for suggesting many valuable improvements to the text.

A Modular Forms

A.1 Dedekind Eta Function

The *Dedekind eta function*, denoted $\eta(\tau)$, is a holomorphic function on the upper half-plane defined by the infinite product

$$\eta(\tau)=q^{1/24}\prod_{n\geq 1}(1-q^n)$$

where $q=\mathrm{e}(\tau)=e^{2\pi\mathbf{i}\tau}$. It is a modular form of weight 1/2 for the modular group $SL_2(\mathbb{Z})$ with multiplier $\epsilon: SL_2(\mathbb{Z})\to\mathbb{C}^*$, which means that

$$\epsilon(\gamma)\eta(\gamma\tau)\mathrm{jac}(\gamma,\tau)^{1/4}=\eta(\tau)$$

for all $\gamma=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in SL_2(\mathbb{Z})$, where $\mathrm{jac}(\gamma,\tau)=(c\tau+d)^{-2}$. The *multiplier system* ϵ may be described explicitly as

$$\epsilon\begin{pmatrix}a&b\\c&d\end{pmatrix}=\begin{cases}\mathrm{e}(-b/24), & c=0,\, d=1\\ \mathrm{e}(-(a+d)/24c+s(d,c)/2+1/8), & c>0\end{cases}\tag{A.1}$$

where $s(d,c)=\sum_{m=1}^{c-1}(d/c)((md/c))$ and $((x))$ is 0 for $x\in\mathbb{Z}$ and $x-\lfloor x\rfloor-1/2$ otherwise. We can deduce the values $\epsilon(a,b,c,d)$ for $c<0$, or for $c=0$ and $d=-1$, by observing that $\epsilon(-\gamma)=\epsilon(\gamma)\,\mathrm{e}(1/4)$ for $\gamma\in SL_2(\mathbb{Z})$.

Let T denote the element of $SL_2(\mathbb{Z})$ such that $\mathrm{tr}(T)=2$ and $T\tau=\tau+1$ for $\tau\in\mathbb{H}$. Observe that

$$\epsilon(T^m\gamma)=\epsilon(\gamma T^m)=\mathrm{e}(-m/24)\epsilon(\gamma)$$

for $m\in\mathbb{Z}$.

A.2 Jacobi Theta Functions

We define the *Jacboi theta functions* $\theta_i(\tau,z)$ as follows for $q=e(\tau)$ and $y=e(z)$.

$$\theta_1(\tau,z)=-iq^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^{n-1})$$

$$\theta_2(\tau,z)=q^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1-q^n)(1+yq^n)(1+y^{-1}q^{n-1})$$

$$\theta_3(\tau,z) = \prod_{n=1}^{\infty}(1-q^n)(1+y\,q^{n-1/2})(1+y^{-1}q^{n-1/2})$$

$$\theta_4(\tau,z) = \prod_{n=1}^{\infty}(1-q^n)(1-y\,q^{n-1/2})(1-y^{-1}q^{n-1/2})$$

Note that there are competing conventions for $\theta_1(\tau,z)$ in the literature and our normalisation may differ from another by a factor of -1 (or possibly $\pm i$).

A.3 Higher Level Modular Forms

The congruence subgroups of the modular group $SL_2(\mathbb{Z})$ that are most relevant for this paper are

$$\Gamma_0(N) \quad = \quad \left\{ \begin{bmatrix} a & b \\ c & d \end{bmatrix} \in SL_2(\mathbb{Z}), c = 0 \bmod N \right\}. \tag{A.2}$$

For $N>1$ a (non-zero) modular form of weight 2 for $\Gamma_0(N)$ is given by

$$\begin{aligned} \Lambda_N(\tau) &= N\,q\partial_q \log\left(\frac{\eta(N\tau)}{\eta(\tau)}\right) \\ &= \frac{N(N-1)}{24}\left(1+\frac{24}{N-1}\sum_{k>0}\sigma(k)(q^k - Nq^{Nk})\right) \end{aligned} \tag{A.3}$$

where $\sigma(k)$ is the divisor function $\sigma(k)=\sum_{d|k} d$.

Observe that a modular form on $\Gamma_0(N)$ is a modular form on $\Gamma_0(M)$ whenever $N|M$, and for some small N the space of forms of weight 2 is spanned by the $\Lambda_d(\tau)$ for d a divisor of N. By contrast, in the case that $N=11$ we have the *newform*

$$f_{11}(\tau) = \eta^2(\tau)\eta^2(11\tau) \tag{A.4}$$

which is a cusp form of weight 2 for $\Gamma_0(11)$ that is not a multiple of $\Lambda_{11}(\tau)$. We meet the newforms

$$f_{14}(\tau) \quad = \quad \eta(\tau)\eta(2\tau)\eta(7\tau)\eta(14\tau,) \tag{A.5}$$

$$f_{15}(\tau) \quad = \quad \eta(\tau)\eta(3\tau)\eta(5\tau)\eta(15\tau), \tag{A.6}$$

$$f_{20}(\tau) \quad = \quad \eta(2\tau)^2\eta(10\tau)^2, \tag{A.7}$$

at $N=14$, $N=15$ and $N=20$, respectively, and together with f_N the functions $\Lambda_d(\tau)$ for $d|N$

span the space of weight 2 forms on $\Gamma_0(N)$ for $N = 11, 14, 15$.

For $N = 23$ there is a two dimensional space of newforms. We may use the basis

$$\begin{aligned} f_{23,a}(\tau) &= \frac{\eta(\tau)^3\eta(23\tau)^3}{\eta(2\tau)\eta(46\tau)} + 3\eta(\tau)^2\eta(23\tau)^2 + 4\eta(\tau)\eta(2\tau)\eta(23\tau)\eta(46\tau) + 4\eta(2\tau)^2\eta(46\tau)^2 \\ f_{23,b}(\tau) &= \eta(\tau)^2\eta(23\tau)^2 \end{aligned} \tag{A.8}$$

satisfying $f_{23,a} = q + O(q^3)$ and $f_{23,b} = q^2 + O(q^3)$. (The normalised Hecke-eigenforms of weight 2 for $\Gamma_0(23)$ are $f_{23,a} - \frac{1}{2}(1 \pm \sqrt{5})f_{23,b}$.)

For $N = 44$ there is a unique newform up to a multiplicative constant. It satisfies

$$f_{44}(\tau) = q + q^3 - 3q^5 + 2q^7 - 2q^9 - q^{11} - 4q^{13} - 3q^{15} + 6q^{17} + 8q^{19} + 2q^{21} - 3q^{23} + 4q^{25} - 5q^{27} + O(q^{28}).$$

See [137] and Chapter 4.D of [138] for more details. A discussion of the ring of weak Jacobi forms of higher level can be found in [139].

B Characters

In §B.1 we give character tables (with power maps and Frobenius–Schur indicators) for each group $G^{(\ell)}$. These were computed with the aid of the computer algebra package GAP4 [98] using the explicit presentations for the $G^{(\ell)}$ that appear in §3.4. We use the abbreviations $a_n = \sqrt{-n}$ and $b_n = (-1 + \sqrt{-n})/2$ in these tables.

The tables in §B.2 furnish the Frame shapes $\Pi_g^{(\ell)}$ and character values $\chi_g^{(\ell)}$ attached to the signed permutation representations (cf. §3.2) of the groups $G^{(\ell)}$ given in §3.4. These Frame shapes and character values can easily be computed by hand; we detail them here explicitly since they can be used to define symbols $n_g|h_g$ which encode the automorphy of the vector-valued mock modular forms $H_g^{(\ell)}$ according to the prescription of §4.8. The symbols $n_g|h_g$ are given in the rows labelled Γ_g in §B.2.

B.2 Euler Characters

The tables in this section describe the Frame shapes $\Pi_g^{(\ell)}$ and twisted Euler characters $\chi_g^{(\ell)}$ attached to each group $G^{(\ell)}$ via the signed permutation representations given in §3.4. The rows labelled $\bar{\Pi}_g^{(\ell)}$ and $\bar{\chi}_g^{(\ell)}$ describe the corresponding data for the (unsigned) permutation representations. According to the discussion of §4.8 the Frame shapes $\Pi_g^{(\ell)}$ and $\bar{\Pi}_g^{(\ell)}$ (or even just the $\Pi_g^{(\ell)}$) can be used to define symbols $n_g|h_g$ which encode the automorphy of the vector-valued mock modular form $H_g^{(\ell)}$; these symbols are given in the rows labelled Γ_g. We write n_g here as a shorthand for $n_g|1$.

Table 14: Twisted Euler characters and Frame shapes at $\ell = 2$

$[g]$	1A	2A	2B	3A	3B	4A	4B	4C	5A	6A	6B

$\chi_g^{(5)}$	6	-6	-2	2	0	0	1	-1	0	0	0
$\bar{\Pi}_g^{(5)}$	1^6	1^6	$1^2 2^2$	$1^2 2^2$	3^2	3^2	$1^1 5^1$	$1^1 5^1$	2^3	$1^2 4^1$	6^1
$\Pi_g^{(5)}$	1^6	$\frac{2^6}{1^6}$	$\frac{2^4}{1^2}$	$1^2 2^2$	3^2	$\frac{6^2}{3^2}$	$1^1 5^1$	$\frac{2^1 10^1}{1^1 5^1}$	$\frac{4^3}{2^3}$	$2^1 4^1$	$\frac{12^1}{6^1}$

We have $\chi_g^{(5)} = \chi_{14}(g)$ and $\bar{\chi}_g^{(5)} = \chi_1(g) + \chi_6(g)$ in the notation of Table 11.

Table 18: Twisted Euler characters and Frame shapes at $\ell = 7$

$[g]$	1A	2A	4A	3AB	6AB
Γ_g	1	1|4	2|8	3	3|4
$\bar{\chi}_g^{(7)}$	4	4	0	1	1
$\chi_g^{(7)}$	4	-4	0	1	-1
$\bar{\Pi}_g^{(7)}$	1^4	1^4	2^2	$1^1 3^1$	$1^1 3^1$
$\Pi_g^{(7)}$	1^4	$\frac{2^4}{1^4}$	$\frac{4^2}{2^2}$	$1^1 3^1$	$\frac{2^1 6^1}{1^1 3^1}$

We have $\chi_g^{(7)} = \chi_6(g) + \chi_7(g)$ in the notation of Table 12.

Table 19: Twisted Euler characters and Frame shapes at $\ell = 13$

$[g]$	1A	2A	4AB
Γ_g	1	1|4	2|8
$\bar{\chi}_g^{(13)}$	2	2	0
$\chi_g^{(13)}$	2	-2	0
$\bar{\Pi}_g^{(13)}$	1^2	1^2	2^1
$\Pi_g^{(13)}$	1^2	$\frac{2^2}{1^2}$	$\frac{4^1}{2^1}$

We have $\chi_g^{(13)} = \chi_3(g) + \chi_4(g)$ in the notation of Table 13.

C Coefficients

In this section we furnish tables of Fourier coefficients of small degree for the vector-valued mock modular forms $H^{(\ell)}_g$ that we attach to the conjugacy classes of the groups $G^{(\ell)}$ for $\ell \in \Lambda$. For each ℓ and $0 < r < \ell$ we give a table that displays the coefficients of $H^{(\ell)}_{g,r}$ for (g ranging over a set of representatives for) each conjugacy class $[g]$ in $G^{(\ell)}$. The first row of each table labels the conjugacy classes, and the first column labels exponents of q (or rather $q^{1/4\ell}$), so that for the table captioned $H^{(\ell)}_{g,r}$ (for some $\ell \in \Lambda$ and $0 < r < \ell$) the entry in the row labelled d and the column labelled nZ is the coefficient of $q^{d/4\ell}$ in the Fourier expansion of $H^{(\ell)}_{g,r}$ for $[g] = nZ$. Occasionally the functions $H^{(\ell)}_g$ and $H^{(\ell)}_{g'}$ coincide for non-conjugate g and g' and when this happens we condense information into a single column, writing $7AB$ in Table 20, for example, to indicate that the entries in that column are Fourier coefficients for both $H^{(2)}_{7A}$ and $H^{(2)}_{7B}$.

D Decompositions

As explained in §4 (see also §5.1) our conjectural proposals for the umbral McKay–Thompson series $H^{(\ell)}_{g,r}(\tau)=\sum_d c^{(\ell)}_{g,r}(d)q^d$ (cf. §§4,C) determine the $G^{(\ell)}$-modules $K^{(\ell)}_{r,d}$ up to isomorphism for $d>0$, at least for those values of d for which we can identify all the Fourier coefficients $c^{(\ell)}_{g,r}(d)$. In this section we furnish tables of explicit decompositions into irreducible representations of $G^{(\ell)}$ for $K^{(\ell)}_{r,d}$, for the first few values of d. The coefficient $c^{(\ell)}_r(d)$ of $H^{(\ell)}_r=H^{(\ell)}_{e,r}$ is non-zero only when $d=n-r^2/4\ell$ for some integer $n\geq 0$. For each of the tables in this section the rows are labelled by the values $4\ell d$, so that the entry in row m and column χ_i indicates the multiplicity of the irreducible representation of $G^{(\ell)}$ with character χ_i (in the notation of the character tables of §B.1) appearing in the $G^{(\ell)}$-module $K^{(\ell)}_{r,m/4\ell}$. One can observe that these tables support Conjectures 5.1, 5.11 and 5.12, and also give evidence in support of the hypothesis that $K^{(\ell)}_{r,d}$ has a decomposition into irreducible representations that factor through $\bar{G}^{(\ell)}$ when r is odd, and has a decomposition into faithful irreducible representations of $G^{(\ell)}$ when r is even.

Mathieu Moonshine in the elliptic genus of K3

Matthias R. Gaberdiel, Stefan Hohenegger and Roberto Volpato

Institut für Theoretische Physik
ETH Zurich
CH-8093 Zürich
Switzerland

Abstract: It has recently been conjectured that the elliptic genus of K3 can be written in terms of dimensions of Mathieu group $\mathbb{M}_{24}$ representations. Some further evidence for this idea was subsequently found by studying the twining genera that are obtained from the elliptic genus upon replacing dimensions of Mathieu group representations by their characters. In this paper we find explicit formulae for all (remaining) twining genera by making an educated guess for their general modular properties. This allows us to identify the decomposition of *all* expansion coefficients in terms of dimensions of $\mathbb{M}_{24}$-representations. For the first 500 coefficients we verify that the multiplicities with which these representations appear are indeed all non-negative integers. This represents very compelling evidence in favour of the conjecture.

1. Introduction

A few months ago Eguchi, Ooguri and Tachikawa [1] observed that the elliptic genus of K3 seems to involve representations of the largest of the Mathieu groups, $\mathbb{M}_{24}$. More specifically, they studied the expansion of the elliptic genus of K3 in terms of elliptic genera of $\mathcal{N}=4$ superconformal representations following [2], and noted that the expansion coefficients can be written in terms of dimensions of representations of $\mathbb{M}_{24}$. This intriguing observation is very reminiscent of a similar phenomenon usually referred to as 'Monstrous Moonshine', namely that the famous J-function has an expansion in terms of characters of the Virasoro algebra whose coefficients are dimensions of Monster group representations, as was first noted by McKay and Thompson.

In the context of Monstrous Moonshine, this observation was eventually explained by the construction of the so-called Monster conformal field theory $V^\natural$ [3], a self-dual conformal field theory at $c=24$ whose space of states is of the form

$$V^\natural = \bigoplus_{n=0}^{\infty} \left(V_n \otimes \mathcal{H}^{\text{Vir}}_{h=n} \right) \ , \tag{1.1}$$

where each V_n is a representation of the Monster group, while $\mathcal{H}^{\text{Vir}}_h$ denotes the irreducible Virasoro representation with conformal weight h and $c=24$. The J-function is then the partition function of $V^\natural$, and its Fourier coefficients are therefore sums of dimensions of irreducible Monster group representations. Furthermore, the automorphism group of $V^\natural$ is the Monster group.

One key observation that provided convincing evidence for (1.1) came from considering the so-called McKay-Thompson series [4]. These are obtained from the J-function upon replacing the expansion coefficients $A_n = \dim(V_n)$ by their corresponding characters, $\mathrm{Tr}_{V_n}(g)$, where g is an element of the Monster group.[1] It was shown by Conway & Norton [5] that these McKay-Thompson series have nice modular properties under congruence subgroups of $SL(2,\mathbb{Z})$. This is what one expects if they arise indeed from (1.1) since they are then equal to the 'twining character', *i.e.* the character with the insertion of the group element g, which has good modular properties based on standard orbifold arguments. For a review of these and other aspects of Monstrous Moonshine see *e.g.* [6].

By analogy to (1.1) the observation of [1] suggests that the states that contribute to the elliptic genus of K3 have the structure

$$\mathcal{H}^{\mathrm{BPS}} = \bigoplus_n \left(H_n \otimes \mathcal{H}_n^{\mathcal{N}=4} \right) \ , \tag{1.2}$$

where the sum runs over all irreducible $\mathcal{N} = 4$ representations that contribute to the elliptic genus, while each H_n is a $\mathbb{M}_{24}$ representation. In order to test this idea it is then again natural to consider the 'twining genera' $\phi_g(\tau, z)$, where one replaces $\dim(H_n)$ by the corresponding character $\mathrm{Tr}_{H_n}(g)$, with $g \in \mathbb{M}_{24}$ [7, 8]. Unfortunately, the dimensions of the irreducible representations of $\mathbb{M}_{24}$ are rather small, and the decomposition of the expansion coefficients of the elliptic genus of K3 in terms of dimensions of $\mathbb{M}_{24}$ representations could only be guessed reliably for the first few coefficients. However, the elliptic genus of K3 is a weak Jacobi form of index one and weight zero [9], and one expects that the twining genera should have similar properties. More specifically, if $g \in \mathbb{M}_{24}$ has order N, then the corresponding twining genus $\phi_g(\tau, z)$ should transform as a weak Jacobi form of index 1 and weight 0 under the congruence subgroup $\Gamma_0(N)$, possibly up to a multiplier system.

In [7, 8] this assumption about the modular properties of the twining genera, together with the explicit knowledge of the first few coefficients, was used in order to determine some of them explicitly. The fact that these two constraints were compatible was already a fairly non-trivial consistency check on the proposal of [1]. Furthermore, for group elements that enjoy an interpretation as an automorphism symmetry of K3 at a suitable point in moduli space, one could calculate the corresponding twining genera directly (see in particular [10]). In this way some of these formulae could be confirmed independently [7].

In this paper we shall complete the analysis of [7, 8] by finding explicit formulae for the remaining conjugacy classes.[2] In particular, we shall make a precise proposal for the structure of the multiplier system that appears in the modular transformation formula, see (3.8) and table 1 below. We can then follow again the strategies outlined in [8] and [7], respectively, to determine the twining genera, using the explicit knowledge of the first few terms. The fact that this procedure is successful is again a fairly non-trivial consistency check of the proposed structure (1.2).

---

[1] These series can be calculated provided one knows how to write the Fourier coefficients of the J-function as $A_n = \dim(V_n)$, but do not require any additional knowledge.

[2] After posting the first version of this paper on the arXiv, we were informed by Tohru Eguchi that they have independently obtained explicit formulae for these twining genera which agree with ours, see [24].

The knowledge of *all* twining genera also leads to another, highly constraining, consistency check. If (1.2) holds and if, for each g, our explicit formula for ϕ_g really corresponds to the trace over $\mathcal{H}^{\rm BPS}$ with the insertion of g, then its coefficients must be equal to $\mathrm{Tr}_{H_n}(g)$ for all n. But knowing these traces for all classes g is sufficient to identify unambiguously H_n as a (possibly reducible) representation of $\mathbb{M}_{24}$. Thus assuming that (1.2) holds, we can *deduce* the decomposition of H_n into irreducible $\mathbb{M}_{24}$ representations for all n. We have calculated the multiplicities explicitly up to order 500 — the results up to order 30 are tabulated in table 4 — and they are all indeed non-negative integers. The fact that this decomposition works out, *i.e.* that each H_n can be written as a direct sum of irreducible representations (with integer multiplicities) is then a highly non-trivial check of (1.2); in fact, we would in some sense prove the proposal of [1] if we could show that *all* of these multiplicities are indeed non-negative integers.

The paper is organised as follows. In section 2 we briefly review some of the properties of the elliptic genus of K3, as well as the proposal of [1]. The modular properties of the twining genera are explained in detail in section 3. In particular, by analogy with the situation for the McKay-Thompson series of Monstrous Moonshine, we make a specific proposal for the structure of the multiplier system. This proposal is then subsequently verified in sections 3.1 and 3.2. In section 3.1 we adopt the strategy of [8] and consider the twining genus at specific values of z, finding explicit formulae for all remaining cases. Section 3.2, on the other hand, employs the method of [7] to write the twining genus in terms of a modular form of weight two; this allows us to check some of the modular properties of the twining genera fairly directly, but the analysis is quite complicated and the details are described in appendix B and C. Finally, we explain in section 4 how the knowledge of all twining genera determines the decomposition of the coefficients in terms of $\mathbb{M}_{24}$ representations, and give the explicit results in table 4. We close with some comments and speculations in section 5.

2. Elliptic genus and twining characters

The elliptic genus of an $\mathcal{N}=2$ superconformal algebra is defined by

$$\phi(\tau,z)=\mathrm{Tr}_{\mathcal{H}_{\rm RR}}\left(q^{L_0-\frac{c}{24}}e^{2\pi i z J_0}(-1)^F\,\bar{q}^{\bar{L}_0-\frac{\bar{c}}{24}}(-1)^{\bar{F}}\right)\,, \tag{2.1}$$

where $q=e^{2\pi i\tau}$, and the trace is taken in the RR sector. For the right-movers (whose modes are denoted by a bar), only the ground states contribute, and hence the above expression is in fact independent of $\bar{q}$. As is well known [9], the modularity properties of conformal field theory together with spectral flow invariance and unitarity imply that the elliptic genus is a *weak Jacobi form* of index $m=\frac{c}{6}$ and weight 0 [11]. A weak Jacobi form $\phi(\tau,z)$ of weight w and index $m\in\mathbb{Z}$ is a function ϕ of $(\tau,z)\in\mathbb{H}\times\mathbb{C}$, where $\mathbb{H}$ is the upper half-plane. It is characterised by the transformation properties

$$\phi\Big(\frac{a\tau+b}{c\tau+d},\frac{z}{c\tau+d}\Big) = (c\tau+d)^w\, e^{2\pi i m \frac{cz^2}{c\tau+d}}\,\phi(\tau,z) \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2,\mathbb{Z})\ , \tag{2.2}$$

$$\phi(\tau, z+\ell\tau+\ell') = e^{-2\pi i m(\ell^2\tau+2\ell z)}\phi(\tau,z) \qquad \ell,\ell'\in\mathbb{Z}\ , \tag{2.3}$$

and has a Fourier expansion

$$\phi(\tau,z) = \sum_{n\geq 0,\ell\in\mathbb{Z}} c(n,\ell)q^n y^\ell \tag{2.4}$$

where $y = e^{2\pi i z}$ and $c(n,\ell) = (-1)^w c(n,-\ell)$. For the case of K3 that will concern us primarily in this paper, $m = 1$ and the elliptic genus equals [12]

$$\phi_{K3}(\tau,z) = 2y + 20 + 2y^{-1} + q\Big(20y^2 - 128y + 216 - 128y^{-1} + 20y^{-2}\Big) + \mathcal{O}(q^2)\ . \tag{2.5}$$

It can be thought of as the partition function of the $\mathcal{N}=2$ half-BPS states of type II string theory on K3.

For the case of K3 the conformal field theory is actually $\mathcal{N}=4$ superconformal, and one can therefore write the elliptic genus in terms of the elliptic genera associated to $\mathcal{N}=4$ superconformal representations. It was observed in [1], following on from earlier work [2], that it can be written as

$$\phi_{K3}(\tau,z) = 24\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac14,l=0}(\tau,z) + \sum_{n=0}^{\infty} A_n\,\mathrm{ch}^{\mathcal{N}=4}_{h=n+\frac14,l=\frac12}(\tau,z)\ , \tag{2.6}$$

where $\mathrm{ch}^{\mathcal{N}=4}_{h=\frac14,l=0}$ is the elliptic genus of the short $\mathcal{N}=4$ representation with $h=\frac14$ and $l=0$ — see [13, 14] for an explicit formula — while

$$\mathrm{ch}^{\mathcal{N}=4}_{h,l=\frac12}(\tau,z) = q^{h-\frac38}\,\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^3} \tag{2.7}$$

is the elliptic genus of a long $\mathcal{N}=4$ representation.[3] The observation of [1] was that the coefficients A_n can be written in terms of dimensions of representations H_n of the Mathieu group $\mathbb{M}_{24}$, so that

$$\begin{aligned}\phi_{K3}(\tau,z) =& (\dim H_{00})\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac14,l=0}(\tau,z) - (\dim H_0)\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac14,l=\frac12}(\tau,z)\\ &+\sum_{n=1}^{\infty}(\dim H_n)\,\mathrm{ch}^{\mathcal{N}=4}_{h=n+\frac14,l=\frac12}(\tau,z)\ ,\end{aligned} \tag{2.8}$$

where

$$\begin{aligned} H_{00} &= \mathbf{23}+\mathbf{1} & H_0 &= 2\cdot\mathbf{1}\\ H_1 &= \mathbf{45}+\overline{\mathbf{45}} & H_2 &= \mathbf{231}+\overline{\mathbf{231}}\\ H_3 &= \mathbf{770}+\overline{\mathbf{770}} & H_4 &= \mathbf{2277}+\overline{\mathbf{2277}}\\ H_5 &= 2\cdot\mathbf{5796} & H_6 &= 2\cdot\mathbf{3520}+2\cdot\mathbf{10395}\end{aligned} \tag{2.9}$$

---

[3] Strictly speaking, the $\mathcal{N}=4$ representation with $n=0$ ($h=\frac14$) is short, and thus (2.7) for $h=\frac14$ is not the elliptic genus of a single representation, but rather involves a sum of representations.

$$H_7 = 2\cdot\mathbf{1771} + 2\cdot\mathbf{2024} + 2\cdot\mathbf{5313} + 2\cdot\mathbf{5796} + 2\cdot\mathbf{5544} + 2\cdot\mathbf{10395}\ . \tag{2.10}$$

The dimensions of the irreducible representations of $\mathbb{M}_{24}$ can be read off from the character table (see table 3). Note that we have absorbed the prefactor 2 in equation (1.11) of [1] into the definition of $A_n = \dim(H_n)$. Then we can write the H_n in terms of real representations, so that, for example, H_1 is the sum of a pair of conjugate representations. The expression for H_7 was given in [7, 8] and differs from what was originally proposed in [1].

It is natural to conjecture that such a decomposition is the hallmark of a deeper structure underlying the elliptic genus of K3, see (1.2). In order to test this idea, the '*twining elliptic genera*', *i.e.* the analogues of the McKay-Thompson series of Monstrous Moonshine, were considered in [7, 8]. These twining genera are obtained from the elliptic genus upon inserting a group element $g \in \mathbb{M}_{24}$ into the trace

$$\phi_g(\tau, z) = \frac{1}{2}\,\mathrm{Tr}_{\mathcal{H}_{\mathrm{RR}}}\Big(g\, q^{L_0 - \frac{c}{24}} e^{2\pi i z J_0} (-1)^F\, \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} (-1)^{\bar{F}}\Big)\ . \tag{2.11}$$

As in [8], we shall normalise the twining characters so that $\phi_{1\mathrm{A}}(\tau,z) = \frac{1}{2}\phi_{K3}(\tau,z)$ is directly equal to the standard weak Jacobi form $\phi_{0,1}$ (see appendix A). Technically speaking, ϕ_g is simply obtained from (2.8) by replacing the dimensions $A_n = \dim(H_n)$ by the trace of g over H_n, $A_n(g) = \mathrm{Tr}_{H_n}(g)$, *i.e.*

$$\begin{aligned}\phi_g(\tau, z) = \frac{1}{2}\Big[&\mathrm{Tr}_{H_{00}}(g)\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=0}(\tau,z) - \mathrm{Tr}_{H_0}(g)\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=\frac{1}{2}}(\tau,z)\\ &+ \sum_{n=1}^{\infty}\mathrm{Tr}_{H_n}(g)\,\mathrm{ch}^{\mathcal{N}=4}_{h=n+\frac{1}{4},l=\frac{1}{2}}(\tau,z)\Big]\ .\end{aligned} \tag{2.12}$$

The character of g only depends on its conjugacy class, and thus the various traces can be read off from the character table of $\mathbb{M}_{24}$, see table 3.

As discussed in more detail in the next section, the twining genera are expected to be Jacobi forms under suitable congruence subgroups of $\mathrm{SL}(2,\mathbb{Z})$. This was confirmed for a number of conjugacy classes in [7, 8]. In the next section we shall complete this programme by determining the twining characters for all remaining conjugacy classes. We shall furthermore show that they have the appropriate modular properties.

3. Modular properties of the twining genera

Using standard conformal field theory arguments, it was argued in [7, 8] that the twining genera ϕ_g should transform as Jacobi forms of index 1 and weight 0, possibly up to a phase, under the congruence subgroup $\Gamma_0(N)$. More specifically, this means that ϕ_g satisfies (2.3) for all $\ell, \ell' \in \mathbb{Z}$, while (2.2) only holds for

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2,\mathbb{Z}) \mid c \equiv 0 \mod N \right\}\ , \tag{3.1}$$

where N is the order of g. In [7], this was explicitly verified for the conjugacy classes[4]

$$1\mathrm{A},\ 2\mathrm{A},\ 3\mathrm{A},\ 4\mathrm{B},\ 5\mathrm{A},\ 6\mathrm{A},\ 7\mathrm{AB},\ 8\mathrm{A},\ 11\mathrm{A},\ 14\mathrm{AB},\ 15\mathrm{AB},\ 23\mathrm{AB}\ . \tag{3.2}$$

These classes are characterised by the condition $\phi_g(\tau, 0) \neq 0$. This is equivalent to the condition that a representative of the class is contained in the subgroup $\mathbb{M}_{23} \subset \mathbb{M}_{24}$, where we think of $\mathbb{M}_{24}$ as a subgroup of S_{24}, the permutation group of 24 points, and define $\mathbb{M}_{23} \subset \mathbb{M}_{24}$ to be the subgroup fixing, say, the first point. All geometric symmetries of K3 at a suitable point in moduli space lie in this subgroup [15, 16], and thus some of them can be calculated from first principles, see also [10]. For all of them the multiplier system turned out to be trivial [7]. The situation is more difficult for the remaining conjugacy classes

$$2\mathrm{B},\ 3\mathrm{B},\ 4\mathrm{A},\ 4\mathrm{C},\ 6\mathrm{B},\ 10\mathrm{A},\ 12\mathrm{A},\ 12\mathrm{B},\ 21\mathrm{AB}\ , \tag{3.3}$$

since there is no *a priori* method to determine them. In [8], explicit formulae were found for the first few of them by combining the constraints from modularity with the knowledge of the first few coefficients.[5] In fact, the analysis of [8] was performed for the NS-sector version of the twining genus, the twining character

$$\chi_g(\tau, z) = \exp\left[2\pi i\left(\frac{\tau}{4} + z + \frac{1}{2}\right)\right]\phi_g\left(\tau, z + \frac{\tau}{2} + \frac{1}{2}\right) \tag{3.4}$$

evaluated at $z = 0$. The advantage of this approach is that one can work with standard modular functions (rather than Jacobi forms). The price one has to pay, on the other hand, is that part of the modular invariance is broken, and that multiplier phases are introduced for certain modular transformations. The latter property turned out to be a blessing in disguise since it suggested that multiplier phases may naturally appear in the modular transformations. Indeed, in [8] the twining characters were determined for all elements g up to order $o(g) \leq 6$, and it was found that the classes in (3.2) and in (3.3) appear to behave very similarly. This suggests that also the twining genera ϕ_g associated to (3.3) should be invariant under $\Gamma_0(N)$, possibly up to non-trivial phases.

The appearance of a multiplier system in the transformation rule for the twining genera is certainly consistent with standard CFT arguments. In fact, this phenomenon also occurs for several McKay-Thompson series (and, more generally, for replicable functions [17]), which are the analogues of the twining characters in the context of Monstrous Moonshine [5]. Recall that each McKay-Thompson series T_g is associated with a certain discrete group

$$\Gamma_0(N|h) = \left\{\begin{pmatrix} a & b/h \\ Nc & d \end{pmatrix} \in \mathrm{SL}(2,\mathbb{R}) \mid a,b,c,d \in \mathbb{Z}\right\}\ , \tag{3.5}$$

where N is the order of the Monster class g, and h is some integer such that $h|\gcd(N, 24)$. This group (sometimes with the inclusion of some Atkin-Lehner involutions of $\Gamma_0(N)$, see

---

[4] The classes which are power conjugated, for example 7A and 7B, give rise to the same twining genus, so that we denote them as a unique class 7AB. The twining genera for the classes 1A, 2A, 3A, 4B, 5A and 6A were also found in [8].

[5] The twining characters for 2B and 4A were also found in [7].

[5]) is the (restricted) eigengroup of T_g, *i.e.* the group under which T_g is invariant up to h-th roots of unity. In particular, T_g is invariant (without any phases) under $\Gamma_0(Nh) \subset \Gamma_0(N)$, while under the cosets of $\Gamma_0(N|h)/\Gamma_0(Nh)$, that are represented by

$$\begin{pmatrix} 1 & 1/h \\ 0 & 1 \end{pmatrix} \qquad \text{and} \qquad \begin{pmatrix} 1 & 0 \\ N & 1 \end{pmatrix} , \tag{3.6}$$

it transforms as

$$T_g\Big(\tau + \frac{1}{h}\Big) = e^{-\frac{2\pi i}{h}} T_g(\tau) \qquad \text{and} \qquad T_g\Big(\frac{\tau}{N\tau+1}\Big) = e^{\pm\frac{2\pi i}{h}} T_g(\tau) . \tag{3.7}$$

The two cosets in (3.6) generate $\Gamma_0(N|h)$, so that (3.7) uniquely determines the multiplier system under $\Gamma_0(N|h)$.

It is then natural to expect that analogous properties hold for the twining genera of $\mathbb{M}_{24}$. The most obvious generalisation would be to require the twining genus ϕ_g, with $g \in \mathbb{M}_{24}$ and $o(g) = N$, to be a Jacobi form (with a suitable multiplier system) of weight 0 and index 1 under $\Gamma_0(N|h)$, for some $h|\gcd(N, 24)$. However, there is one immediate problem with this proposal: for $h > 1$, $\Gamma_0(N|h)$ is not contained in $\mathrm{SL}(2,\mathbb{Z})$, and it is not clear how to define the action of the whole $\Gamma_0(N|h)$ on Jacobi forms.[6] Thus we can only analyse the modular properties under the subgroup $\Gamma_0(N|h) \cap \mathrm{SL}(2,\mathbb{Z}) \cong \Gamma_0(N)$. This then leads to the following conjecture:

Conjecture. *For all the conjugacy classes g of $\mathbb{M}_{24}$, the twining character $\phi_g(\tau, z)$ is a Jacobi form of index one and weight zero under $\Gamma_0(N)$, with a multiplier system defined by*[7]

$$\phi_g\Big(\frac{a\tau+b}{c\tau+d}, \frac{z}{c\tau+d}\Big) = e^{\frac{2\pi i cd}{Nh}}\, e^{\frac{2\pi i\, cz^2}{c\tau+d}}\, \phi_g(\tau, z) , \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N) , \tag{3.8}$$

where N is the order of g and $h|\gcd(N, 12)$. The multiplier system is trivial ($h = 1$) if and only if g contains a representative in $\mathbb{M}_{23} \subset \mathbb{M}_{24}$.

For the classes in (3.2) that have representatives in $\mathbb{M}_{23}$ the conjecture has been shown in [7]. In the next subsections, we will show that the conjecture is also true for the remaining classes, *i.e.* the elements in (3.3), with the values of h as given in table 1.

Class	2B	3B	4A	4C	6B	10A	12A	12B	21AB
h	2	3	2	4	6	2	2	12	3

Table 1: Value of h for the conjugacy classes in (3.3).

Because of these non-trivial multiplier systems, the analysis is quite difficult, and we have applied two different strategies. First we have refined the method of [8] by considering the twining genus $\phi_g(\tau, z)$ as a function of τ at special values of z. These values are chosen in such a way that the z-dependent exponential factor in the transformation formula (3.8) cancels (part of) the h-th root of unity. If the phase is completely removed (as is the case for all but two classes), the resulting function is a modular function for $\Gamma_0(N)$, which can be easily analysed. Using this approach (as well as some guess work for the other two cases) we have succeeded in finding closed formulae for all the characters with $h > 1$, see section 3.1.

---

[6] A well-defined action of $\mathrm{SL}(2,\mathbb{R})$ on Jacobi forms can be defined, see [11]. However, this action does not respect the periodicity condition on z, and thus does not seem to be relevant in the current context.

[7] We thank Miranda Cheng and John Duncan for pointing out an error in a previous version of this formula.

The other strategy follows the idea advocated in [7] and consists of expanding the twining genus in terms of standard weak Jacobi forms. This reduces the problem to finding a suitable modular form of weight two. This problem can be studied systematically, but usually leads to more complicated computations. In section 3.2 we shall explain the salient features of this analysis, while the explicit formulae for all characters are given in appendix C.

3.1 Characters evaluated at fixed values of z

Let $\phi(\tau, z)$ be a weak Jacobi form of weight 0 and index 1, transforming as in (3.8), for some N and h with $h|\gcd(N, 12)$. Then, for any $k \in \mathbb{Z}$, we have

$$\begin{aligned}
\phi\Big(\frac{a\tau+b}{c\tau+d}, \frac{k}{h}\Big) &= \phi\Big(\frac{a\tau+b}{c\tau+d}, \frac{k(c\tau+d)}{h(c\tau+d)}\Big) = e^{\frac{2\pi i cd}{Nh}}\, e^{\frac{2\pi i\, k^2 c(c\tau+d)}{h^2}}\, \phi\Big(\tau, \frac{k(c\tau+d)}{h}\Big) \\
&= e^{\frac{2\pi i cd}{Nh}}\, e^{\frac{2\pi i k^2 c(c\tau+d)}{h^2}}\, e^{-2\pi i(\frac{k^2c^2}{h^2}\tau + 2\frac{k^2 cd}{h^2})}\, \phi\Big(\tau, \frac{kd}{h}\Big) \qquad (3.9)\\
&= e^{2\pi i cd(-\frac{k^2}{h^2} + \frac{1}{Nh})}\, \phi\Big(\tau, \frac{kd}{h}\Big)\ , \qquad \text{for} \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)\ ,
\end{aligned}$$

where we have used (2.3) in the second line. (Note that $c \in N\mathbb{Z}$, and hence $\frac{c}{h} \in \mathbb{Z}$.) Let us define

$$\Phi^{(h)}(\tau) = \frac{1}{\varphi(h)} \sum_{k \in (\mathbb{Z}/h\mathbb{Z})^*} \phi\Big(\tau, \frac{k}{h}\Big)\ , \qquad (3.10)$$

where $(\mathbb{Z}/h\mathbb{Z})^*$ is the set of totatives of h, *i.e.* the positive integers smaller than h that are relatively prime to h, and the Euler totient function $\varphi(h)$ is the number of all such totatives. This definition simplifies considerably in concrete examples

$$\Phi^{(h)}(\tau) = \phi(\tau, \tfrac{1}{h})\ , \qquad h = 2, 3, 4, 6\ , \qquad (3.11)$$

$$\Phi^{(12)}(\tau) = \frac{1}{2}\big(\phi(\tau, \tfrac{1}{12}) + \phi(\tau, \tfrac{5}{12})\big)\ , \qquad (3.12)$$

because $\phi(\tau, z) = \phi(\tau, -z)$ for Jacobi forms of even weight. It is easy to verify that, for all $h|12$, the condition $\gcd(k, h) = 1$ implies $k^2 \equiv 1 \mod h$. Furthermore, for $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$, the condition $ad - bc = 1$ implies $\gcd(d, h) = 1$, so that the map $k \mapsto kd$ is bijective on $(\mathbb{Z}/h\mathbb{Z})^*$. Thus we conclude

$$\Phi^{(h)}\Big(\frac{a\tau+b}{c\tau+d}\Big) = e^{2\pi i cd(-\frac{1}{h^2} + \frac{1}{Nh})}\, \Phi^{(h)}(\tau)\ , \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)\ , \qquad (3.13)$$

and it follows immediately that $\Phi^{(h)}(\tau)$ is invariant under $\Gamma_0(Nh)$. Since h divides N, the cosets of $\Gamma_0(N)/\Gamma_0(Nh)$ are generated by $\left(\begin{smallmatrix} 1 & 0 \\ N & 1 \end{smallmatrix}\right)$, and the phase in (3.13) cancels under this transformation if and only if

$$\frac{N}{h} \equiv 1 \mod h \ . \tag{3.14}$$

Thus $\Phi^{(h)}$ is actually invariant under $\Gamma_0(N)$ if (3.14) holds. In this case, it is easy to obtain a closed formula for $\Phi_g^{(h)}$. In fact, with the exception of $N = 21$, all the groups $\Gamma_0(N)$ we are interested in are genus zero[8], so that all modular functions must be rational functions of the corresponding Hauptmodul.

As it turns out the condition (3.14) is satisfied for all classes in (3.3), with the exception of 4A and 12A for which $h = 2$ and hence $N/h \equiv 0 \mod h$. In all other cases we found a modular function for $\Gamma_0(N)$ which matches the first few coefficients in the q-expansion that can be determined from (2.9) and (2.10). This function is either a constant or a fractional linear transformation of the Hauptmodul (in fact, a McKay-Thompson series) for $\Gamma_0(N)$. For the class 21AB it is a rational function in the McKay-Thompson series $T_{[21\mathrm{B}]}$ and $T_{[21\mathrm{D}]}$, that are modular functions for $\Gamma_0(21)$ (for a q-expansion of these McKay Thompson series see appendix A). Our explicit expressions are:

$$\begin{aligned}
\Phi^{(2)}_{2\mathrm{B}}(\tau) &= -4 && h=2\\
\Phi^{(3)}_{3\mathrm{B}}(\tau) &= -3 && h=3\\
\Phi^{(4)}_{4\mathrm{C}}(\tau) &= -2 && h=4\\
\Phi^{(6)}_{6\mathrm{B}}(\tau) &= -1 && h=6\\
\Phi^{(2)}_{10\mathrm{A}}(\tau) &= -4\frac{\eta(5\tau)\eta(2\tau)^5}{\eta(10\tau)\eta(\tau)^5} = \frac{-20}{T_{[10\mathrm{E}]}-3} - 4 && h=2\\
\Phi^{(12)}_{12\mathrm{B}}(\tau) &= -2 - 6\frac{\eta(2\tau)^2\eta(3\tau)\eta(12\tau)^3}{\eta(\tau)^3\eta(4\tau)\eta(6\tau)^2} = \frac{-6}{T_{[12\mathrm{I}]}-3} - 2 && h=12\\
\Phi^{(3)}_{21AB}(\tau) &= \frac{1}{2} - \frac{7}{2}\frac{\eta(3\tau)\eta(7\tau)^3}{\eta(\tau)^3\eta(21\tau)} = \frac{-T_{[21\mathrm{B}]}+7T_{[21\mathrm{D}]}+15}{-2T_{[21\mathrm{B}]}+2} && h=3\ .
\end{aligned} \tag{3.15}$$

Since $\phi_g(\tau, z)$ is a Jacobi form of index one, we have

$$\phi_g(\tau,z) = \phi_g(\tau,0)\,\frac{\vartheta_2(\tau,z)^2}{\vartheta_2(\tau,0)^2} + \phi_g(\tau,\tfrac{1}{2})\,\frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2}\ , \tag{3.16}$$

so that (3.15) immediately gives a formula for the corresponding character at generic z

$$\phi_g(\tau,z) = \Phi_g^{(h)}(\tau)\,\varphi(h)\left(\sum_{k\in(\mathbb{Z}/h\mathbb{Z})^*}\vartheta_1\Big(\tau,\frac{k}{h}\Big)^2\right)^{-1}\vartheta_1(\tau,z)^2\ , \tag{3.17}$$

where we also used the fact that, for all g in (3.3),

$$\phi_g(\tau,0) = \frac{1}{2}\,\mathrm{Tr}_{\mathbf{23}\oplus\mathbf{1}}(g) = 0\ . \tag{3.18}$$

---

[8] Genus zero here means that the Riemann surface obtained by quotienting the upper half-plane $\mathbb{H}$ by $\Gamma_0(N)$ has the topology of the sphere.

The remaining two cases, 4A and 12A, are not invariant under $\Gamma_0(N)$, and thus require more work. For 4A a closed formula was already found in [7, 8]

$$\phi_{4\mathrm{A}}(\tau,\tfrac{1}{2}) = -4 - 32\frac{\eta(2\tau)^2\eta(8\tau)^4}{\eta(\tau)^4\eta(4\tau)^2} = -4 - \frac{32}{T_{8E}(\tau)+4} \qquad h=2\ , \tag{3.19}$$

and it is easy to verify that the corresponding $\phi_{4\mathrm{A}}(\tau,z)$ transforms as in (3.8) under $\Gamma_0(4)$ with $h=2$. We have also managed to find a closed formula for the NS-character χ_g of 12A at $z=\frac{1}{6}$

$$\chi_{12\mathrm{A}}(\tau,\tfrac{1}{6}) = \frac{\eta(\tau)\eta(\frac{3\tau}{2})^2\eta(4\tau)^2\eta(6\tau)^3}{\eta(2\tau)\eta(\frac{\tau}{2})^2\eta(12\tau)^2\eta(3\tau)^3}\ , \tag{3.20}$$

from which the function $\phi_{12\mathrm{A}}(\tau,z)$ can be reconstructed. However, it is easier to analyse the modular properties of $\phi_{12\mathrm{A}}(\tau,z)$ using the methods described in the next subsection.

3.2 Studying the modular forms of weight two

Every weak Jacobi form of index 1 can be written as a linear combination of the standard Jacobi forms $\phi_{0,1}$ and $\phi_{-2,1}$ of weight 0 and -2, respectively (see appendix A), where the coefficients lie in the space of modular forms under the relevant subgroup of $\mathrm{SL}(2,\mathbb{Z})$ [11]. In particular,

$$\phi_g(\tau,z) = B_g\,\phi_{0,1}(\tau,z) + F_g(\tau)\,\phi_{-2,1}(\tau,z)\ , \tag{3.21}$$

where B_g is the constant

$$B_g = \frac{1}{12}\phi_g(\tau,0) = \frac{1}{24}\,\mathrm{Tr}_{\mathbf{23}\oplus\mathbf{1}}(g)\ , \tag{3.22}$$

while F_g is a suitable modular form of weight two. If g is in (3.2), the phases in (3.8) are trivial, and $F_g \in M_2(\Gamma_0(N))$, where $M_k(\Gamma)$ denotes the space of modular form of weight k under the group Γ. In [7], it has been shown that, for all g in (3.2), there is a unique $F_g \in M_2(\Gamma_0(N))$ matching the known coefficients of the q-expansion of ϕ_g (see also appendix C).

If g is one of the classes in (3.3), then $B_g=0$ and the conjecture (3.8) would imply that F_g transforms as

$$F_g\Big(\frac{a\tau+b}{c\tau+d}\Big) = e^{\frac{2\pi icd}{Nh}}(c\tau+d)^2F(\tau)\ , \qquad \begin{pmatrix} a & b\\ c & d\end{pmatrix} \in \Gamma_0(N)\ , \tag{3.23}$$

where N is the order of g and $h|\gcd(N,12)$. In particular, this means that

$$F_g \in M_2(\Gamma_0(Nh))\ , \qquad F_g^h \in M_{2h}(\Gamma_0(N))\ . \tag{3.24}$$

Conversely, if these conditions hold, then F_g transforms as a modular form of weight 2 under $\Gamma_0(N)$ up to a certain h-th root of unity $e^{\frac{2\pi ircd}{Nh}}$, for some $r\in\mathbb{Z}$.

For all g in (3.3), we have found modular forms $F_g \in M_2(\Gamma_0(Nh))$ for the above values of h that reproduce the first few coefficients of q as determined from (2.9) and (2.10), and satisfy $F_g^h \in M_{2h}(\Gamma_0(N))$. The explicit expressions for F_g (and F_g^h) in terms of suitable bases of $M_2(\Gamma_0(Nh))$ (and $M_{2h}(\Gamma_0(N))$) are quite complicated, and are therefore only given in appendix C.

It remains to prove that the h-th root of unity $e^{\frac{2\pi ircd}{Nh}}$ in the modular transformation of F_g is the same as in (3.8), *i.e.* that $r = 1$. We are mainly interested in the class 12A because the other cases have already been dealt with in the previous subsection. For 12A we have found $h = 2$, and since the phase is non-trivial (as can be easily checked), the only possibility is $r = 1$. This completes our analysis.

4. Decomposition into irreducible representations

In the previous sections, we provided explicit expressions for all twining genera, matching the first few coefficients in (2.12) and transforming as in (3.8). The knowledge of all such characters also leads to another very stringent consistency check of the proposal. It allows us to check whether there are indeed underlying $\mathbb{M}_{24}$ representations H_n such that $A_n(g) = \mathrm{Tr}_{H_n}(g)$, where $A_n(g)$ is the coefficient replacing A_n in ϕ_g, see (2.12).

In order to understand how this works, let us assume that $A_n(g) = \mathrm{Tr}_{H_n}(g)$, where H_n is a $\mathbb{M}_{24}$ representation which we decompose as

$$H_n = \bigoplus_{i=1}^{26} h_{n,i}\, R_i \ , \tag{4.1}$$

where $i = 1, \ldots, 26$ labels the different irreducible representations of $\mathbb{M}_{24}$, numbered as in table 3. To start with we rewrite (2.12) as

$$-\mathrm{Tr}_{H_0}(g) + \sum_{n=1}^{\infty} \mathrm{Tr}_{H_n}(g) q^n = q^{\frac{1}{8}} \frac{\eta(\tau)^3}{\vartheta_1(\tau,z)^2} \Big(2\phi_g(\tau,z) - \mathrm{Tr}_{H_{00}}(g)\, \mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=0}(\tau,z) \Big) \ , \tag{4.2}$$

where we have used (2.7). Next we recall that the characters of a finite group satisfy the orthonormality relations

$$\sum_g c(g)\ \overline{\mathrm{Tr}_R(g)}\ \mathrm{Tr}_{R'}(g) = \begin{cases} 1 & \text{if } R \cong R' \\ 0 & \text{otherwise,} \end{cases} \tag{4.3}$$

where R and R' are two irreducible representations of $\mathbb{M}_{24}$. Here the sum runs over all conjugacy classes of $\mathbb{M}_{24}$, and $c(g)^{-1}$ is the order of the centraliser of g

$$c(g) = \frac{n(g)}{|\mathbb{M}_{24}|} \ , \qquad \text{with} \quad |\mathbb{M}_{24}| = 2^{10} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 23 \tag{4.4}$$

the order of $\mathbb{M}_{24}$ and $n(g)$ the number of elements in the conjugacy class of g. Using (4.3) we now obtain from (4.2)

$$-2\delta_{i,1} + \sum_{n=1}^{\infty} h_{n,i}\, q^n = q^{\frac{1}{8}} \frac{\eta(\tau)^3}{\vartheta_1(\tau,z)^2} \Big(2 \sum_g c(g) \overline{\mathrm{Tr}_{R_i}(g)}\, \phi_g(\tau,z) - (\delta_{i,1} + \delta_{i,2})\, \mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=0}(\tau,z) \Big) \ , \tag{4.5}$$

where $i = 1, \ldots, 26$. In deriving (4.5) we have used that $H_{00} = R_1 \oplus R_2 = \mathbf{1} \oplus \mathbf{23}$ and $H_0 = 2 \cdot R_1 = 2 \cdot \mathbf{1}$. For $i > 2$, (4.5) simplifies, and we obtain

$$\sum_{n=1}^{\infty} h_{n,i}\, q^n = -2q^{\frac{1}{8}} \frac{\sum_g c(g) \overline{\mathrm{Tr}_{R_i}(g)}\, F_g(\tau)}{\eta(\tau)^3} = -2 \frac{\sum_g c(g) \overline{\mathrm{Tr}_{R_i}(g)}\, F_g(\tau)}{\prod_{n=1}^{\infty}(1-q^n)^3}\,, \qquad i > 2\,, \quad (4.6)$$

where we used (3.21), as well as (3.22) and (4.3) again. Furthermore, we have plugged in the explicit expression for $\phi_{-2,1}$ from (A.7).

The character values $\mathrm{Tr}_{R_i}(g)$ are given in table 3, and the explicit values of $c(g)$ are tabulated in table 2. The analysis of the previous sections provide closed formulae for the twining characters $\phi_g(\tau, z)$ for all conjugacy classes g in $\mathbb{M}_{24}$, so that the right hand side of (4.5) can be easily evaluated. Thus we can determine the multiplicities $h_{n,i}$ explicitly. The statement that there are underlying $\mathbb{M}_{24}$ representations H_n is now simply equivalent to the property of the multiplicities $h_{n,i}$ to be non-negative integers. We have worked out these multiplicities for $n \leq 500$, and all of them are indeed non-negative integers; the explicit values for $n \leq 30$ are listed in table 4.

Since all the characters we have constructed have real coefficients, the multiplicities of conjugate representations are always equal, so that all H_n are real representations, as expected. It is also remarkable that the multiplicities of the real irreducible representations in (4.1) are always even, at least, up to $n = 500$ (see also [7]). This suggests that the actual symmetry group may be slightly bigger than the Mathieu group $\mathbb{M}_{24}$.

5. Conclusions

In this paper we have accumulated compelling evidence for the conjecture of Eguchi, Ooguri and Tachikawa [1] that the states contributing to the elliptic genus of K3 carry an action of the Mathieu group $\mathbb{M}_{24}$. More specifically, we have found closed form expressions for the twining genera of K3 for all conjugacy classes of $\mathbb{M}_{24}$, thus completing the programme initiated in [7, 8]. We have shown that the twining genera transform indeed as Jacobi forms of index one and weight zero under $\Gamma_0(N)$, where N is the order of the corresponding group element. The twining genera of the conjugacy classes that have no representative contained in $\mathbb{M}_{23} \subset \mathbb{M}_{24}$ have a non-trivial multiplier system, which we have identified, see eq. (3.8).

The explicit knowledge of all twining genera allows one to determine the decomposition of the elliptic genus of K3 in terms of $\mathbb{M}_{24}$ representations, and we have checked that the multiplicities with which these representations appear are indeed non-negative integers, at least for the first 500 coefficients — see also table 4 for explicit results for $n \leq 30$. This is a highly non-trivial consistency check; indeed, if we were able to show that *all* of these multiplicities are non-negative integers, this would effectively prove the conjecture of [1].

Another, more conceptual, proof of the conjecture would consist of constructing explicitly the action of $\mathbb{M}_{24}$ on the BPS states contributing to the elliptic genus of K3. For some generators in $\mathbb{M}_{23} \subset \mathbb{M}_{24}$ this can be done fairly directly since they describe geometric automorphisms of the K3 surface [15, 16], see also [18] for some recent progress in this direction. However, it seems unlikely that these purely geometrical symmetries will suffice to account for the full $\mathbb{M}_{24}$ symmetry of the elliptic genus. In fact, one may guess that one will need to consider the full moduli space of the non-linear sigma model in order to achieve this. Thus at least some of the required symmetries may have an interpretation in terms of truly stringy symmetries, such as *e.g.* T-duality. It would be very interesting to explore these ideas in more detail [19].

On a more technical note, it is amusing to note (see also [8]) that, in contrast to the McKay-Thompson series in Monstrous Moonshine [5], not all twining genera seem to be Hauptmoduls for genus zero congruence subgroups (although many are). For example, the twining character 21AB, for which the relevant modular group, $\Gamma_0(21)$, is not genus 0. This fact is also reflected in equation (3.15) where we have given the explicit expression of $\Phi^{(3)}_{21\mathrm{AB}}(\tau)$ as a modular form of $\Gamma_0(21)$. Unlike the remaining twining characters, it cannot be written as a rational function of a single modular function (the Hauptmodul) but rather involves two functions (the McKay-Thompson series $T_{[21\mathrm{B}]}$ and $T_{[21\mathrm{D}]}$). It would be very interesting to understand what the significance of the genus zero property in this context is.

Acknowledgments

We thank Terry Gannon for useful communications and John McKay for inspiring discussions. The research of MRG and SH is partially supported by a grant from the Swiss National Science Foundation, and the research of RV is supported by an INFN Fellowship.

Table 4: Multiplicities $h_{n,i}$ in the decomposition of the representations $H_n = \oplus_{i=1}^{26} h_{n,i} R_i$, for $n \leq 30$. The representations R_i are numbered as in table 3, in the second row the dimension is given. Pairs of conjugate representations are listed together, because they always appear with the same multiplicities.

A. Definitions

Our conventions for the Dedekind eta and the Jacobi theta functions are

$$\begin{aligned}
\eta(\tau) &= q^{\frac{1}{24}} \prod_{n=1}^{\infty}(1-q^n) \\
\vartheta_1(\tau,z) &= -iq^{\frac{1}{8}} y^{\frac{1}{2}} \prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^{n-1}) \\
\vartheta_2(\tau,z) &= 2\,q^{\frac{1}{8}} \cos(\pi z) \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^n)(1+y^{-1}q^n) \\
\vartheta_3(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^{n-1/2})(1+y^{-1}q^{n-1/2}) \\
\vartheta_4(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1-yq^{n-1/2})(1-y^{-1}q^{n-1/2}) \quad .
\end{aligned} \tag{A.1}$$

Under modular transformations the ϑ and η functions transform as

$$\vartheta_1(\tau+1,z) = e^{\frac{2\pi i}{8}}\,\vartheta_1(\tau,z) \qquad \vartheta_1(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = -(-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_1(\tau,z)\ , \tag{A.2}$$

$$\vartheta_2(\tau+1,z) = e^{\frac{2\pi i}{8}}\,\vartheta_2(\tau,z) \qquad \vartheta_2(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_4(\tau,z)\ , \tag{A.3}$$

$$\vartheta_3(\tau+1,z) = \vartheta_4(\tau,z) \qquad \vartheta_3(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_3(\tau,z)\ , \tag{A.4}$$

$$\vartheta_4(\tau+1,z) = \vartheta_3(\tau,z) \qquad \vartheta_4(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_2(\tau,z)\ , \tag{A.5}$$

as well as

$$\eta(\tau+1) = e^{\frac{2\pi i}{24}}\,\eta(\tau) \qquad \eta(-\tfrac{1}{\tau}) = (-i\tau)^{\frac{1}{2}}\,\eta(\tau)\ . \tag{A.6}$$

The theta constants $\vartheta_a(\tau)$ are defined as $\vartheta_a(\tau) \equiv \vartheta_a(\tau, z=0)$. The standard weak Jacobi forms $\phi_{0,1}$ and $\phi_{-2,1}$ of index 1 and weight 0 and 2 can be defined as [11]

$$\phi_{0,1}(\tau,z) = 4\sum_{i=2}^{4}\frac{\vartheta_i(\tau,z)^2}{\vartheta_i(\tau,0)^2}\ , \qquad \phi_{-2,1}(\tau,z) = -\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^6}\ . \tag{A.7}$$

For completeness we give here the first few terms of the McKay-Thompson series that appear in our analysis

$$T_{[8E]} = \frac{1}{q} + 4q + 2q^3 - 8q^5 - q^7 + 20q^9 - 2q^{11} - 40q^{13} + \cdots\ , \tag{A.8}$$

$$T_{[10E]} = \frac{1}{q} + q + 2q^2 + 2q^3 - 2q^4 - q^5 - 4q^7 - 2q^8 + 5q^9 + 2q^{10} + 8q^{12} + \cdots\ , \tag{A.9}$$

$$T_{[12I]} = \frac{1}{q} + 2q + q^3 - 2q^7 - 2q^9 + 2q^{11} + 4q^{13} + 3q^{15} + \cdots\ , \tag{A.10}$$

$$T_{[21B]} = \frac{1}{q} - q - q^2 + q^3 + 2q^4 - q^5 + 3q^6 - q^7 - q^8 - 2q^9 + q^{11} + \cdots\ , \tag{A.11}$$

$$T_{[21D]} = \frac{1}{q} + 5q + 8q^2 + 16q^3 + 26q^4 + 44q^5 + 66q^6 + 104q^7 + \cdots\ , \tag{A.12}$$

see [17, 20] for more information about these series.

B. Modular forms for $\Gamma_0(N)$

In this section, we will describe a basis of the space $M_k(\Gamma_0(N))$ of modular forms of weight k under $\Gamma_0(N)$. Our main references for this section are [21, 22].

The space $M_k(\Gamma_0(N))$ of modular forms of weight k splits into a direct sum

$$M_k(\Gamma_0(N)) = E_k(\Gamma_0(N)) \oplus S_k(\Gamma_0(N)) \ , \tag{B.1}$$

where $S_k(\Gamma_0(N))$ is the space of cusp forms, *i.e.* forms they vanish at all the cusps[9] of $\overline{\mathbb{H}/\Gamma_0(N)}$. The space $E_k(\Gamma_0(N))$ is defined as the unique subspace satisfying (B.1) that is invariant under the action of all Hecke operators [22].

A convenient basis for $E_k(\Gamma_0(N))$ is given by (generalised) Eisenstein series [23]. Let

$$E_k(\tau) = -\frac{B_k}{2k} + \sum_{n=1}^{\infty}\Big(\sum_{d|n} d^{k-1}\Big)q^n \tag{B.2}$$

be the standard Eisenstein series of weight k, where B_k are the Bernoulli numbers. For $k > 2$, k even, E_k is a modular form of weight k under $SL(2,\mathbb{Z})$, whereas

$$E_2\Big(\frac{a\tau+b}{c\tau+d}\Big) = (c\tau+d)^2 E_2(\tau) - \frac{1}{4\pi i}c(c\tau+d) \ . \tag{B.3}$$

The definition of the Eisenstein series can be generalised to include modular forms under $\Gamma_0(N)$. In particular,[10]

$$\psi^{(N)} = q\frac{\partial}{\partial q}\log\frac{\eta(N\tau)}{\eta(\tau)} = E_2(\tau) - NE_2(N\tau) \tag{B.4}$$

is a modular form of weight 2 under $\Gamma_0(N)$. The (generalised) Eisenstein series

$$E_k^{\chi_m}(\tau) = \sum_{n=1}^{\infty}\Big(\sum_{d|n}\overline{\chi_m(d)}\,\chi_m(n/d)\,d^{k-1}\Big)\,q^n \ , \tag{B.5}$$

where k is even and χ_m is a non-trivial Dirichlet character of modulus m, is a modular form of weight k under $\Gamma_0(m^2)$. The only cases we need are

$$E_k^{(9)} = E_k^{\chi_3} \in M_k(\Gamma_0(9)) \ , \quad E_k^{(16)} = E_k^{\chi_4} \in M_k(\Gamma_0(16)) \ , \quad E_k^{(144)} = E_k^{\chi_{12}} \in M_k(\Gamma_0(144)) \ , \tag{B.6}$$

where χ_3, χ_4 and χ_{12} are the primitive Dirichlet characters of modulus 3, 4 and 12, that are uniquely determined by

$$\chi_3(2) = -1 \ , \qquad \chi_4(3) = -1 \ , \qquad \chi_{12}(5) = \chi_{12}(7) = -1 \ . \tag{B.7}$$

---

[9] The cusps correspond to $\Gamma_0(N)$-orbits in $\mathbb{Q}\cup\{\infty\}$, with $\Gamma_0(N)$ acting by fractional linear transformations.

[10] The Eisenstein series $\psi^{(N)}$ are related to the modular forms $\phi^{(N)}$ in [7] by $\psi^{(N)} = \frac{N-1}{24}\phi^{(N)}(\tau)$.

In general, the space $S_k(\Gamma_0(N))$ is not generated by Eisenstein series. It is obvious that if $M|N$, then $M_k(\Gamma_0(M)) \subset M_k(\Gamma_0(N))$. More generally, it is easy to see that if $f \in M_k(\Gamma_0(M))$, then, for any divisor n of N/M, $f(n\tau) \in \Gamma_0(N)$. For all $M|N$ and $n|(N/M)$, we define the map

$$\alpha_n : M_k(\Gamma_0(M)) \to M_k(\Gamma_0(N)) \tag{B.8}$$

$$f(\tau) \mapsto \alpha_n(f)(\tau) = f(n\tau) \ . \tag{B.9}$$

The map α_n sends cusp forms to cusp forms and the union of the images $\alpha_n(S_k(\Gamma_0(N/n))) \subseteq S_k(\Gamma_0(N))$, for all $n|N$, $n > 1$, is called the *old subspace* of cusp forms. The complement of the old subspace which is invariant under all Hecke operators is called the *new subspace*. Thus, we have a decomposition

$$S_k(\Gamma_0(N)) = \bigoplus_{M|N} \bigoplus_{n|(N/M)} \alpha_n(S_k(\Gamma_0(M))_{new}) \ , \tag{B.10}$$

where $S_k(\Gamma_0(M))_{new}$ is the new subspace for $\Gamma_0(M)$. A basis for $S_k(\Gamma_0(M))_{new}$ for the cases of interest are listed below; a more extended list of their coefficients can be found at `http://modi.countnumber.de/`. Some Fourier expansions have been computed using SAGE (`http://www.sagemath.org/`).

- Cusp forms $f_M \in S_2(\Gamma_0(M))_{new}$ — if there is more than one generator, the different generators are denoted by $f_{M,a}, f_{M,b}, \ldots$.

$$f_{21}(\tau) = q - q^2 + q^3 - q^4 - 2q^5 - q^6 - q^7 + 3q^8 + q^9 + 2q^{10} + \cdots \tag{B.11}$$

$$f_{23,a}(\tau) = q - q^3 - q^4 - 2q^6 + 2q^7 - q^8 + 2q^9 + 2q^{10} + \cdots \tag{B.12}$$

$$f_{23,b}(\tau) = -q^2 + 2q^3 + q^4 - 2q^5 - q^6 - 2q^7 + 2q^8 + 2q^{10} + \cdots \tag{B.13}$$

$$f_{24}(\tau) = q - q^3 - 2q^5 + q^9 + 4q^{11} - 2q^{13} + 2q^{15} + 2q^{17} + \cdots \tag{B.14}$$

$$f_{48}(\tau) = q + q^3 - 2q^5 + q^9 - 4q^{11} - 2q^{13} - 2q^{15} + 2q^{17} + \cdots \tag{B.15}$$

$$f_{63,a}(\tau) = q + q^2 - q^4 + 2q^5 - q^7 - 3q^8 + 2q^{10} - 4q^{11} - 2q^{13} + \cdots \tag{B.16}$$

$$f_{63,b}(\tau) = q + q^4 + q^7 - 6q^{10} + 2q^{13} - 5q^{16} + \cdots \tag{B.17}$$

$$f_{63,c}(\tau) = q^2 - 2q^5 - q^8 + 2q^{11} + q^{14} + 2q^{17} + \cdots \tag{B.18}$$

$$f_{72}(\tau) = q + 2q^5 - 4q^{11} - 2q^{13} - 2q^{17} - 4q^{19} + \cdots \tag{B.19}$$

$$f_{144,a}(\tau) = q + 4q^7 + 2q^{13} - 8q^{19} - 5q^{25} + 4q^{31} + \cdots \tag{B.20}$$

$$f_{144,b}(\tau) = q + 2q^5 + 4q^{11} - 2q^{13} - 2q^{17} + 4q^{19} + \cdots \ . \tag{B.21}$$

- Cusp forms $g_M \in S_4(\Gamma_0(M))_{new}$

$$g_5(\tau) = q - 4q^2 + 2q^3 + 8q^4 - 5q^5 - 8q^6 + 6q^7 - 23q^9 + \cdots \tag{B.22}$$

$$g_6(\tau) = q - 2q^2 - 3q^3 + 4q^4 + 6q^5 + 6q^6 - 16q^7 - 8q^8 + 9q^9 + \cdots \tag{B.23}$$

$$g_8(\tau) = q - 4q^3 - 2q^5 + 24q^7 - 11q^9 - 44q^{11} + 22q^{13} + \cdots \tag{B.24}$$

$$g_{10}(\tau) = q + 2q^2 - 8q^3 + 4q^4 + 5q^5 - 16q^6 - 4q^7 + 8q^8 + 37q^9 + \cdots \tag{B.25}$$

$$g_{12}(\tau) = q + 3q^3 - 18q^5 + 8q^7 + 9q^9 + 36q^{11} - 10q^{13} - 54q^{15} + \cdots \ . \tag{B.26}$$

- Cusp forms $h_M \in S_6(\Gamma_0(M))_{new}$

$$\begin{aligned}
h_3(\tau) =& q - 6q^2 + 9q^3 + 4q^4 + 6q^5 - 54q^6 - 40q^7 + 168q^8 + \cdots && \text{(B.27)}\\
h_{7,a}(\tau) =& q - 10q^2 - 14q^3 + 68q^4 - 56q^5 + 140q^6 - 49q^7 - 360q^8 + \cdots && \text{(B.28)}\\
h_{7,b}(\tau) =& q + 4q^2 - 2q^4 - 14q^5 - 84q^6 + 49q^7 - 10q^8 + \cdots && \text{(B.29)}\\
h_{7,c}(\tau) =& q^2 - 6q^3 + 9q^4 + 10q^5 - 30q^6 + 11q^8 + \cdots && \text{(B.30)}\\
h_{21,a}(\tau) =& q + q^2 - 9q^3 - 31q^4 - 34q^5 - 9q^6 - 49q^7 - 63q^8 + \cdots && \text{(B.31)}\\
h_{21,b}(\tau) =& q + 5q^2 + 9q^3 - 7q^4 + 94q^5 + 45q^6 - 49q^7 - 195q^8 + \cdots && \text{(B.32)}\\
h_{21,c}(\tau) =& q - 6q^2 - 9q^3 + 4q^4 + 78q^5 + 54q^6 + 49q^7 + 168q^8 + \cdots && \text{(B.33)}\\
h_{21,d}(\tau) =& q + 10q^2 + 9q^3 + 68q^4 - 106q^5 + 90q^6 - 49q^7 + 360q^8 + \cdots \ . && \text{(B.34)}
\end{aligned}$$

- Cusp forms $k_M \in S_8(\Gamma_0(M))_{new}$

$$k_2(\tau) = q - 8q^2 + 12q^3 + 64q^4 - 210q^5 - 96q^6 + 1016q^7 - 512q^8 + \cdots \ . \qquad \text{(B.35)}$$

- Cusp forms $l_M \in S_{12}(\Gamma_0(M))_{new}$

$$\begin{aligned}
l_3(\tau) =& q + 78q^2 - 243q^3 + 4036q^4 - 5370q^5 - 18954q^6 - 27760q^7 + \cdots && \text{(B.36)}\\
l_{6,a}(\tau) =& q + 32q^2 + 243q^3 + 1024q^4 + 3630q^5 + 7776q^6 + 32936q^7 + \cdots && \text{(B.37)}\\
l_{6,b}(\tau) =& q - 32q^2 - 243q^3 + 1024q^4 + 5766q^5 + 7776q^6 + 72464q^7 + \cdots && \text{(B.38)}\\
l_{6,c}(\tau) =& q - 32q^2 + 243q^3 + 1024q^4 - 11730q^5 - 7776q^6 - 50008q^7 + \cdots \ . && \text{(B.39)}
\end{aligned}$$

To summarise, $M_k(\Gamma_0(N))$ is thus generated by

$$\begin{array}{lll}
k=2: & \psi^{(n)}(\tau) & \text{for } n|N\,,\ n>1 \\
 & E_2^{\chi_m}(n\tau) & \text{for } nm^2|N\,,\ m>1 \\
 & f_{M,a}(n\tau),\ f_{M,b}(n\tau),\ \ldots & \text{for } nM|N \\
 & & \\
k=4: & E_4(n\tau) & \text{for } n|N \\
 & E_4^{\chi_m}(n\tau) & \text{for } nm^2|N\,,\ m>1 \\
 & g_{M,a}(n\tau),\ g_{M,b}(n\tau),\ \ldots & \text{for } nM|N\ ,
\end{array} \qquad \text{(B.40)}$$

and the cases $k = 6, 8, \ldots$ *etc.* are similar to $k = 4$, with $g_{M,a}$ replaced by $h_{M,a}$, *etc.*

C. The modular forms of weight two

With the conventions of the previous appendix we can now give the explicit expressions for the modular forms $F_g \in M_2(\Gamma_0(Nh))$, as well as for $F_g^h \in M_{2h}(\Gamma_0(N))$. For the classes in (3.2) for which $h = 1$, the relevant formulae are [7]

$$\begin{aligned}
F_{2\mathrm{A}}(\tau) &= 16\psi^{(2)}(\tau)\\
F_{3\mathrm{A}}(\tau) &= 9\psi^{(3)}(\tau)\\
F_{4\mathrm{B}}(\tau) &= -4\psi^{(2)}(\tau) + 8\psi^{(4)}(\tau)\\
F_{5\mathrm{A}}(\tau) &= 5\psi^{(5)}(\tau)\\
F_{6\mathrm{A}}(\tau) &= -2\psi^{(2)}(\tau) - 3\psi^{(3)}(\tau) + 6\psi^{(6)}(\tau)\\
F_{7\mathrm{AB}}(\tau) &= \frac{7}{2}\psi^{(7)}(\tau)\\
F_{8\mathrm{A}}(\tau) &= -2\psi^{(4)}(\tau) + 4\psi^{(8)}(\tau)\ ,\\
F_{11\mathrm{A}}(\tau) &= \frac{11}{5}\big(\psi^{(11)}(\tau) - \eta(\tau)^2\eta(11\tau)^2\big)\\
F_{14\mathrm{AB}}(\tau) &= \frac{1}{6}\big(-2\psi^{(2)}(\tau) - 7\psi^{(7)}(\tau) + 14\psi^{(14)}(\tau) - 14\eta(\tau)\eta(2\tau)\eta(7\tau)\eta(14\tau)\big)\\
F_{15\mathrm{AB}}(\tau) &= \frac{1}{8}\big(-3\psi^{(3)}(\tau) - 5\psi^{(5)}(\tau) + 15\psi^{(15)}(\tau) - 15\eta(\tau)\eta(3\tau)\eta(5\tau)\eta(15\tau)\big)\\
F_{23\mathrm{AB}} &= \frac{23}{22}\big(\psi^{(23)}(\tau) - f_{23,a}(\tau) + 3f_{23,b}(\tau)\big)\ .
\end{aligned} \tag{C.1}$$

In the remaining cases we have found — the formulae for $F_{2\mathrm{B}}$ and $F_{4\mathrm{A}}$ were already obtained in [7]

- $g = 2\mathrm{B}$, $h = 2$

$$F_{2\mathrm{B}}(\tau) = -24\psi^{(2)}(\tau) + 16\psi^{(4)}(\tau) \qquad \in M_2(\Gamma_0(4)) \tag{C.2}$$

$$F_{2\mathrm{B}}(\tau)^2 = -16E_4(\tau) + 256E_4(2\tau) \qquad \in M_4(\Gamma_0(2)) \tag{C.3}$$

- $g = 3\mathrm{B}$, $h = 3$

$$F_{3B}(\tau) = -6\psi^{(3)}(\tau) + \frac{9}{2}\psi^{(9)}(\tau) - \frac{9}{2}E_2^{(9)}(\tau) \qquad \in M_2(\Gamma_0(9)) \tag{C.4}$$

$$F_{3B}(\tau)^3 = -1944\psi^{(3)}(\tau)^3 + \frac{45}{2}E_6(\tau) - \frac{2187}{2}E_6(3\tau) \qquad \in M_6(\Gamma_0(3)) \tag{C.5}$$

- $g = 4\mathrm{A}$, $h = 2$

$$F_{4\mathrm{A}}(\tau) = 4\psi^{(2)}(\tau) - 12\psi^{(4)}(\tau) + 8\psi^{(8)}(\tau) \qquad \in M_2(\Gamma_0(8)) \tag{C.6}$$

$$F_{4\mathrm{A}}(\tau)^2 = -16E_4(2\tau) + 256E_4(4\tau) \qquad \in M_4(\Gamma_0(4)) \tag{C.7}$$

- $g = 4\mathrm{C}$, $h = 4$

$$F_{4\mathrm{C}}(\tau) = 2\psi^{(4)}(\tau) - 6\psi^{(8)}(\tau) + 4\psi^{(16)}(\tau) - 4E_2^{(16)}(\tau) \qquad \in M_2(\Gamma_0(16)) \tag{C.8}$$

$$F_{4\mathrm{C}}(\tau)^4 = -\tfrac{32}{17}E_8(2\tau) + \tfrac{8192}{17}E_8(4\tau) - 16k_2(\tau) - \tfrac{512}{17}k_2(2\tau) \qquad \in M_8(\Gamma_0(4)) \tag{C.9}$$

- $g = 6\mathrm{B}$, $h = 6$

$$\begin{aligned} F_{6\mathrm{B}}(\tau) = &-\tfrac{3}{2}\psi^{(2)}(\tau) - 2\psi^{(3)}(\tau) + \psi^{(4)}(\tau) + 6\psi^{(6)}(\tau) + \tfrac{3}{2}\psi^{(9)}(\tau) - 4\psi^{(12)}(\tau) \\ &- \tfrac{9}{2}\psi^{(18)}(\tau) + 3\psi^{(36)}(\tau) - \tfrac{3}{2}E_2^{(9)}(\tau) \\ &- 9E_2^{(9)}(2\tau) - 12E_2^{(9)}(4\tau) \qquad \in M_2(\Gamma_0(36)) \end{aligned} \tag{C.10}$$

$$\begin{aligned} F_{6\mathrm{B}}(\tau)^6 = &\, c_1 E_{12}(\tau) + c_2 E_{12}(2\tau) + c_3 E_{12}(3\tau) + c_4 E_{12}(6\tau) + c_5 \Delta(\tau) \\ &+ c_6 \Delta(2\tau) + c_7 \Delta(3\tau) + c_8 \Delta(6\tau) + c_9 l_{6,a}(\tau) \\ &+ c_{10} l_{6,b}(\tau) + c_{11} l_{6,c}(\tau) + c_{12} l_3(\tau) + c_{13} l_3(2\tau) \qquad \in M_{12}(\Gamma_0(6)) \end{aligned} \tag{C.11}$$

where $\Delta(\tau) = ((240E_4(\tau))^3 - (504E_6(\tau)^2))/1728$ and

p	1	2	3	4	5	6	7	8	9	10	11	12	13
c_p	$\frac{1}{22951565}$	$-\frac{4096}{22951565}$	$-\frac{531441}{22951565}$	$\frac{2176782336}{22951565}$	$-\frac{189277}{58735}$	$-\frac{91776}{3455}$	$\frac{37712628}{58735}$	$\frac{27713664}{3455}$	$-\frac{297}{140}$	$-\frac{308}{145}$	$-\frac{95}{52}$	$-\frac{194697}{71978}$	$\frac{304128}{2117}$

- $g =$10A, $h = 2$

$$\begin{aligned} F_{10\mathrm{A}}(\tau) = &\, \psi^{(2)}(\tau) - \frac{2}{3}\psi^{(4)}(\tau) + \frac{5}{3}\psi^{(5)}(\tau) - 5\psi^{(10)}(\tau) \\ &+ \frac{10}{3}\psi^{(20)}(\tau) - \frac{10}{3}\eta(2\tau)^2\eta(10\tau)^2 \qquad \in M_2(\Gamma_0(20)) \end{aligned} \tag{C.12}$$

$$\begin{aligned} F_{10\mathrm{A}}(\tau)^2 = &\, \frac{1}{39}E_4(\tau) - \frac{16}{39}E_4(2\tau) - \frac{625}{39}E_4(5\tau) + \frac{10000}{39}E_4(10\tau) \\ &- \frac{10}{3}g_{10}(\tau) - \frac{35}{13}g_5(\tau) + \frac{40}{13}g_5(2\tau) \qquad \in M_4(\Gamma_0(10)) \end{aligned} \tag{C.13}$$

- $g = 12\mathrm{A}$, $h = 2$

$$\begin{aligned} F_{12\mathrm{A}}(\tau) = &-\frac{1}{2}\psi^{(2)}(\tau) + \frac{3}{2}\psi^{(4)}(\tau) + \frac{3}{2}\psi^{(6)}(\tau) - \psi^{(8)}(\tau) \\ &- \frac{9}{2}\psi^{(12)}(\tau) + 3\psi^{(24)}(\tau) - 3f_{24}(\tau) \qquad \in M_2(\Gamma_0(24)) \end{aligned} \tag{C.14}$$

$$\begin{aligned} F_{12\mathrm{A}}(\tau)^2 = &\, \frac{1}{5}E_4(2\tau) - \frac{16}{5}E_4(4\tau) - \frac{81}{5}E_4(6\tau) + \frac{1296}{5}E_4(12\tau) \\ &- 3g_{12}(\tau) - 3g_6(\tau) + \frac{24}{5}g_6(2\tau) \qquad \in M_4(\Gamma_0(12)) \end{aligned} \tag{C.15}$$

- $g = 12\mathrm{B}$, $h = 12$

$$\begin{aligned} F_{12\mathrm{B}}(\tau) = {}& \frac{1}{8}\psi^{(4)}(\tau) - \frac{3}{8}\psi^{(8)}(\tau) - \frac{1}{2}\psi^{(12)}(\tau) + \frac{1}{4}\psi^{(16)}(\tau) + \frac{3}{2}\psi^{(24)}(\tau) + \frac{3}{8}\psi^{(36)}(\tau) \\ & - \psi^{(48)}(\tau) - \frac{9}{8}\psi^{(72)}(\tau) + \frac{3}{4}\psi^{(144)}(\tau) - \frac{3}{2}E_2^{(9)}(4\tau) - 9E_2^{(9)}(8\tau) - 12E_2^{(9)}(16\tau) \\ & - \frac{1}{4}E_2^{(16)}(\tau) - 3E_2^{(16)}(3\tau) - \frac{27}{4}E_2^{(16)}(9\tau) - \frac{3}{4}E_2^{(144)}(\tau) - \frac{3}{2}f_{24}(2\tau) \\ & - \frac{27}{2}f_{24}(6\tau) - \frac{3}{4}f_{48}(\tau) + \frac{27}{4}f_{48}(3\tau) + \frac{9}{2}f_{72}(2\tau) - \frac{9}{4}f_{144,b}(\tau) \ \in M_2(\Gamma_0(144)) \end{aligned} \tag{C.16}$$

We have also worked out the expansion of $F^{12}_{12\mathrm{B}}$ in terms of generators of $M_{24}(\Gamma_0(12))$, but since the final expression is exceedingly complicated, we shall not spell it out here.

- $g = 21\mathrm{AB}$, $h = 3$

$$\begin{aligned} F_{21\mathrm{AB}}(\tau) = {}& \frac{1}{8}\psi^{(3)}(\tau) + \frac{7}{32}\psi^{(7)}(\tau) - \frac{3}{32}\psi^{(9)}(\tau) - \frac{7}{8}\psi^{(21)}(\tau) + \frac{21}{32}\psi^{(63)}(\tau) + \frac{3}{32}E_2^{(9)}(\tau) \\ & - \frac{147}{32}E_2^{(9)}(7\tau) - \frac{21}{32}f_{21}(\tau) + \frac{189}{32}f_{21}(3\tau) - \frac{63}{32}f_{63,a}(\tau) \qquad \in M_2(\Gamma_0(63)) \end{aligned} \tag{C.17}$$

$$\begin{aligned} F_{21\mathrm{AB}}(\tau)^3 = {}& -\tfrac{1}{169936}\,E_6(\tau) + \tfrac{729}{169936}\,E_6(3\tau) + \tfrac{117649}{169936}\,E_6(7\tau) - \tfrac{85766121}{169936}E_6\,(21\tau) \\ & - \tfrac{85641}{36608}\,h_3(\tau) - \tfrac{352947}{36608}\,h_3(7\tau) - \tfrac{64491}{94600}\,h_{7a}(\tau) - \tfrac{11263}{9728}\,h_{7b}(\tau) - \tfrac{18277}{4864}\,h_{7c}(\tau) \\ & - \tfrac{2740311}{189200}\,h_{7a}(3\tau) + \tfrac{66339}{9728}\,h_{7b}(3\tau) - \tfrac{250047}{4864}\,h_{7c}(3\tau) - \tfrac{441}{352}\,h_{21a}(\tau) \\ & - \tfrac{1323}{8800}\,h_{21b}(\tau) - \tfrac{735}{512}\,h_{21c}(\tau) - \tfrac{3087}{6400}\,h_{21d}(\tau) \qquad \in M_6(\Gamma_0(21))\ . \end{aligned} \tag{C.18}$$

Rademacher sums, moonshine and gravity

John F. R. Duncan*
Igor B. Frenkel†

1 March 2012

Abstract

In 1939 Rademacher derived a conditionally convergent series expression for the elliptic modular invariant, and used this expression—the first Rademacher sum—to verify its modular invariance. By generalizing Rademacher's approach we construct bases for the spaces of automorphic integrals of arbitrary even integer weight, for groups commensurable with the modular group. Our methods provide explicit expressions for the Fourier expansions of the Rademacher sums we construct at arbitrary cusps, and illuminate various aspects of the structure of the spaces of automorphic integrals, including the actions of Hecke operators.

We give a moduli interpretation for a class of groups commensurable with the modular group which includes all those that are associated to the Monster via monstrous moonshine. We show that within this class the monstrous groups can be characterized just in terms of the behavior of their Rademacher sums. In particular, the genus zero property of monstrous moonshine is encoded naturally in the properties of Rademacher sums.

Just as the ellptic modular invariant gives the graded dimension of the moonshine module, the exponential generating function of the Rademacher sums associated to the modular group furnishes the bi-graded dimension of the Verma module for the Monster Lie algebra. This result generalizes naturally to all the groups of monstrous moonshine, and recovers a certain family of monstrous Lie algebras recently introduced by Carnahan.

Our constructions suggest conjectures relating monstrous moonshine to a distinguished family of chiral three dimensional quantum gravities, and relating monstrous Lie algebras and their Verma modules to the second quantization of this family of chiral three dimensional quantum gravities.

1 Introduction

1.1 Monstrous moonshine

A remarkable coincidence between the coefficients of the elliptic modular invariant

$$J(z) = \mathrm{e}(-z) + \sum_{n>0} c(n)\,\mathrm{e}(nz), \quad \mathrm{e}(nz) = \exp(2\pi \mathbf{i} nz), \tag{1.1.1}$$

and the dimensions of the irreducible representations of the *Monster group*, denoted $\mathbb{M}$, led McKay and Thompson [Tho79b] to conjecture the existence of a naturally defined infinite dimensional representation

$$V = V_{-1} \oplus V_1 \oplus V_2 \oplus \cdots \tag{1.1.2}$$

for the Monster group, with the property that $\dim V_n = c(n)$. Thompson [Tho79a] also proposed to consider the modular properties of the series

$$T_g(z) = \mathrm{e}(-z) + \sum_{n>0} (\mathrm{tr}|_{V_n} g)\,\mathrm{e}(nz), \tag{1.1.3}$$

for any $g \in \mathbb{M}$, the function $J(z)$ of (1.1.1) being recovered upon taking $g = e$ in (1.1.3). It is clear from the presentation (1.1.3) that $T_g(z)$ is invariant under the *translation group*, which we denote $B(\mathbb{Z})$ and which is generated by the translation $z \mapsto z + 1$. In the case (1.1.1) that g is the identity element, the invariance extends to the full modular group $PSL_2(\mathbb{Z})$. This leads us to the question: what is special about the invariance groups Γ_g of the McKay–Thompson series (1.1.3)?

In their remarkable paper [CN79], Conway and Norton collected an overwhelming number of coincidences and, in particular, formulated the *moonshine conjecture*:

> The series $T_g(z)$ is the normalized hauptmodul of a genus zero group Γ_g lying between $\Gamma_0(N)$ and its normalizer in $PSL_2(\mathbb{R})$, for each $g \in \mathbb{M}$.

The conjecture of McKay and Thompson was proven in [FLM88] by the explicit construction of a vertex operator algebra $V^\natural$ invariant under the Monster group. It was also shown in [FLM88] that the McKay–Thompson series $T_g(z)$ satisfy the moonshine conjecture of Conway and Norton for all elements g in a subgroup of $\mathbb{M}$ arising as an involution centralizer. Finally, a complete proof of the moonshine conjecture was given by Borcherds in [Bor92]. However, in spite of all the subsequent spectacular developments related to the Monster, the consensus of the experts (cf. e.g. [CMS04]), is that "the real nature of moonshine is still remote".

1.2 Rademacher sums

In this paper we shed new light on the properties of the McKay–Thompson series associated to the Monster, including the mysterious genus zero phenomena. It turns out that the McKay–Thompson series admit presentations as sums over the coset space $B(\mathbb{Z})\backslash\Gamma_g$. The prototype for this is the following expression for the modular invariant $J(z)$ which was originally derived by Rademacher in [Rad39].

$$J(z) + 12 = \mathrm{e}(-z) + \lim_{K\to\infty} \sum_{\substack{0<c<K \\ -K^2<d<K^2 \\ (c,d)=1}} \mathrm{e}\left(-\frac{az+b}{cz+d}\right) - \mathrm{e}\left(-\frac{a}{c}\right) \tag{1.2.1}$$

The integers a and b occurring in each summand of (1.2.1) are chosen so that $ad - bc = 1$. This expression (1.2.1) is remarkably simple, but the convergence is rather subtle. (See [Kno90] for a nice exposition.) The subtraction of the constant $\mathrm{e}(-a/c)$ in (1.2.1) ensures the existence of the limit in what is otherwise a highly divergent series. The Rademacher sum (1.2.1) has been generalized to various discrete subgroups of $PSL_2(\mathbb{R})$ in a series of papers by Knopp (cf. [Kno61a], [Kno61b], [Kno62a], [Kno62b]).

Given $\Gamma < PSL_2(\mathbb{R})$ we write Γ_∞ for the subgroup of Γ that fixes ∞. If Γ is commensurable with the modular group $PSL_2(\mathbb{Z})$ and has the property that $\Gamma_\infty = B(\mathbb{Z})$, then we may naturally associate a Rademacher sum to Γ by setting

$$R_{\Gamma}^{(-1)}(z) = \mathrm{e}(-z) + \lim_{K\to\infty} \sum_{\gamma\in(B(\mathbb{Z})\backslash\Gamma)^{\times}_{\leq K}} \mathrm{e}(-\gamma\cdot z) - \mathrm{e}(-\gamma\cdot\infty), \tag{1.2.2}$$

where the sum here is taken over the *rectangle*

$$(B(\mathbb{Z})\backslash\Gamma)^{\times}_{\leq K} = \left\{ \gamma = B(\mathbb{Z}) \begin{bmatrix} * & * \\ c & d \end{bmatrix} \in B(\mathbb{Z})\backslash\Gamma \mid 0 < c \leq K,\ -K^2 \leq d \leq K^2 \right\} \tag{1.2.3}$$

(cf. §3.1). In (1.2.3) we write $\left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$ for the image in $PSL_2(\mathbb{R})$ of a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ in $SL_2(\mathbb{R})$, and in (1.2.2) we write $\gamma\cdot z$ for $(az+b)/(cz+d)$ and $\gamma\cdot\infty$ for a/c when $\gamma = \left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$.

In general the series $R_{\Gamma}^{(-1)}(z)$ defines an abelian integral for Γ, meaning that we have

$$R_{\Gamma}^{(-1)}(\gamma\cdot z) = R_{\Gamma}^{(-1)}(z) + \omega(\gamma) \tag{1.2.4}$$

for some function $\omega : \Gamma \to \mathbb{C}$. We show in §6.1 that the Rademacher sum $R_{\Gamma}^{(-1)}(z)$ is Γ-invariant if and only if Γ has genus zero. Even more than this, we show (also in §6.1) that when Γ has genus zero the function

$$R_{\Gamma}^{(-1)}(z) - \frac{1}{2}\mathrm{c}_{\Gamma}(-1,0) \tag{1.2.5}$$

is the normalized hauptmodul for Γ (cf. §2.5), for a certain constant $\mathrm{c}_{\Gamma}(-1,0)$. This constant $\mathrm{c}_{\Gamma}(-1,0)$ turns out to be the *Rademacher constant associated to* Γ as defined in [Nor84] in the case that Γ has genus zero (cf. §5.1).

Rademacher's proof of the validity of the presentation (1.2.1) relies upon explicit formulas for the Fourier coefficients of $J(z)$. These formulas may be given in terms of Kloosterman sums and Bessel functions, and are recovered from the expression

$$\mathrm{c}_{\Gamma}(m,n) = \sum_{\gamma\in B(\mathbb{Z})\backslash\Gamma/B(\mathbb{Z})} \mathrm{Kl}_{\gamma}(m,n)\,\mathrm{Bl}_{\gamma}(m,n) \tag{1.2.6}$$

upon taking $\Gamma = PSL_2(\mathbb{Z})$ and $m = -1$, and allowing n to range over $\mathbb{Z}$. Writing $c(\gamma)$ for $|c|$ when $\gamma = \left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$, the functions $\mathrm{Kl}_{\gamma}(m,n)$ and $\mathrm{Bl}_{\gamma}(m,n)$ are defined as follows (cf. §3.2), for $\gamma \in \Gamma$.

$$\mathrm{Kl}_{\gamma}(m,n) = \mathrm{e}(m\gamma\cdot\infty)\,\mathrm{e}(-n\gamma^{-1}\cdot\infty) \tag{1.2.7}$$

$$\mathrm{Bl}_{\gamma}(m,n) = 2\pi\mathbf{i}\,\mathrm{Res}_{\xi=0}\,\mathrm{e}(mc(\gamma)^{-2}\xi^{-1})\,\mathrm{e}(n\xi)\mathrm{d}\xi \tag{1.2.8}$$

Note that $\mathrm{Kl}_{\gamma}(m,n)$ and $\mathrm{Bl}_{\gamma}(m,n)$ are well-defined complex numbers only when $c(\gamma) \neq 0$, and in this case

$$\mathrm{Kl}_\gamma(m,n) = \mathrm{e}\left(\frac{ma+nd}{c}\right), \quad \mathrm{Bl}_\gamma(m,n) = \sum_{k\geq 0}\left(\frac{2\pi\mathbf{i}}{c}\right)^{2k+2}\frac{m^{k+1}}{(k+1)!}\frac{n^k}{k!}, \tag{1.2.9}$$

for $\gamma = \left[\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right]$ and $c > 0$. The expression (1.2.6) with $\Gamma = PSL_2(\mathbb{Z})$ and $m = -1$ is, up to elementary transformations, the formula for the n-th coefficient of the elliptic modular invariant given originally by Rademacher in [Rad38]. More generally, the formula (1.2.6) recovers the Fourier coefficients (other than the constant term) of the Rademacher sum $R_\Gamma^{(-1)}(z)$, for Γ an arbitrary group commensurable with $PSL_2(\mathbb{Z})$ and satisfying $\Gamma_\infty = B(\mathbb{Z})$. The following formula (cf. Theorem 3.3.2) encodes the relationship precisely.

$$R_\Gamma^{(-1)}(z) = \mathrm{e}(-z) + \frac{1}{2}\mathrm{c}_\Gamma(-1,0) + \sum_{n>0}\mathrm{c}_\Gamma(-1,n)\,\mathrm{e}(nz) \tag{1.2.10}$$

1.3 Conjugate Rademacher sums

It is striking that the constant term in the Fourier expansion (1.2.10) of the Rademacher sum $R_\Gamma^{(-1)}(z)$ is $\mathrm{c}_\Gamma(-1,0)/2$ and not $\mathrm{c}_\Gamma(-1,0)$, given that the coefficient of $\mathrm{e}(nz)$ in (1.2.10) is exactly $\mathrm{c}_\Gamma(-1,n)$ for $n > 0$. One may also observe that the formula (1.2.6) defining the values $\mathrm{c}_\Gamma(-1,n)$ makes sense for arbitrary integers $n \in \mathbb{Z}$, and so it is natural to ask what rôle is played by the $\mathrm{c}_\Gamma(-1,n)$ for $n < 0$? An answer to this question is obtained when we consider the *conjugate Rademacher sum associated to* Γ, denoted $\bar{R}_\Gamma^{(-1)}(z)$, and defined by setting

$$\bar{R}_\Gamma^{(-1)}(z) = \mathrm{e}(-\bar{z}) + \lim_{K\to\infty}\sum_{\gamma\in(B(\mathbb{Z})\backslash\Gamma)^\times_{\leq K}} \mathrm{e}(-\gamma\cdot\bar{z}) - \mathrm{e}(-\gamma\cdot\infty) \tag{1.3.1}$$

for $z \in \mathbb{H}$. The conjugate Rademacher sum $\bar{R}_\Gamma^{(-1)}(z)$ defines an anti-holomorphic function on $\mathbb{H}$. At first glance it appears that we should recover the classical Rademacher sum $R_\Gamma^{(-1)}(z)$ after substituting $\bar{z}$ for z in $\bar{R}_\Gamma^{(-1)}(z)$, since the expressions defining $R_\Gamma^{(-1)}(z)$ and $\bar{R}_\Gamma^{(-1)}(\bar{z})$ would appear to coincide, but in fact the delicate limit defining the Rademacher sums behaves very differently depending on which half plane the variable z lies in, and the difference $R_\Gamma^{(-1)}(z) - \bar{R}_\Gamma^{(-1)}(\bar{z})$ can be rather far from vanishing. As an illustration of this, we show in §3.3 that the Fourier expansion of the conjugate Rademacher sum $\bar{R}_\Gamma^{(-1)}(z)$ in terms of the anti-holomorphic exponential $\mathrm{e}(\bar{z})$ recovers the values $\mathrm{c}_\Gamma(-1,n)$ for $n < 0$ as Fourier coefficients. More precisely, we establish the following counterpart to (1.2.10) (cf. Theorem 3.3.3).

$$\bar{R}_\Gamma^{(-1)}(z) = \mathrm{e}(-\bar{z}) - \frac{1}{2}\mathrm{c}_\Gamma(-1,0) - \sum_{n<0}\mathrm{c}_\Gamma(-1,n)\,\mathrm{e}(n\bar{z}) \tag{1.3.2}$$

We demonstrate in §3.4 that the holomorphic function $\bar{R}_{\Gamma}^{(-1)}(\bar{z})$ is also an abelian integral (cf. Theorem 3.4.4). More than this, the difference

$$R_{\Gamma}^{(-1)}(z) - \bar{R}_{\Gamma}^{(-1)}(z) \tag{1.3.3}$$

is a Γ-invariant harmonic function on $\mathbb{H}$ (cf. Theorem 3.4.6).

The Γ-invariance of the function (1.3.3) entails a remarkable formula for $\bar{R}_{\Gamma}^{(-1)}(z)$ in the case that Γ has genus zero. For since the holomorphic Rademacher sum $R_{\Gamma}^{(-1)}(z)$ is Γ-invariant in the genus zero case, the anti-holomorphic function $\bar{R}_{\Gamma}^{(-1)}(z)$ must also be Γ-invariant. Given our knowledge (1.3.2) of the Fourier expansion of $\bar{R}_{\Gamma}^{(-1)}(z)$ it follows that $\bar{R}_{\Gamma}^{(-1)}(z)$ must be identically constant, and furthermore, this constant must be $-\mathrm{c}_{\Gamma}(-1,0)/2$. In the case that $\Gamma = PSL_2(\mathbb{Z})$ we have $\mathrm{c}_{\Gamma}(-1,0) = 24$, and we thus obtain the remarkable identity

$$\mathrm{e}(-\bar{z}) + \lim_{K\to\infty} \sum_{\substack{0<c<K \\ -K^2<d<K^2 \\ (c,d)=1}} \mathrm{e}\left(-\frac{a\bar{z}+b}{c\bar{z}+d}\right) - \mathrm{e}\left(-\frac{a}{c}\right) = -12, \tag{1.3.4}$$

where in each summand a and b are integers chosen so that $ad - bc = 1$. This implies that the function $R_{\Gamma}^{(-1)}(z) - \bar{R}_{\Gamma}^{(-1)}(z)$ is a (non-normalized) hauptmodul for Γ when Γ has genus zero, and in particular,

$$\mathrm{c}_{\Gamma}(-1,n) = \delta_{-1,n} \tag{1.3.5}$$

for $n < 0$. We recover the normalized hauptmodul for Γ (cf. §2.5) by considering the sum $R_{\Gamma}^{(-1)}(z) + \bar{R}_{\Gamma}^{(-1)}(z)$.

1.4 Solid tori

It was observed in [CN79] that each group attached to the Monster via monstrous moonshine may be described as a group of *$n\|h$-type*, meaning a discrete group $\Gamma < PSL_2(\mathbb{R})$ of the form $\Gamma = \Gamma_0(n\|h) + S$ for some $n, h \in \mathbb{Z}^+$ with $h|(n,24)$, and S a subgroup of the group of exact divisors of n/h. For such n, h, and S, the group $\Gamma_0(n\|h)+S$ contains and normalizes $\Gamma_0(nh)$, and has the property that $(\Gamma_0(n\|h)+S)_\infty = B(\mathbb{Z})$. (We recall the precise definition of $\Gamma_0(n\|h)+S$ in §2.5.)

We shed new light on the groups of $n\|h$-type by demonstrating in §6.2 that they solve a natural family of moduli problems for elliptic curves equipped with certain kinds of extra structure. As we will explain presently, a common feature of all the members of this family is a choice of filling of the elliptic curve in question; that is, a solid torus whose boundary is the given elliptic curve. Hence, we interpret the $n\|h$-type groups as defining moduli of (decorated) solid tori.

The fact that each group Γ of $n\|h$-type satisfies $\Gamma_\infty = B(\mathbb{Z})$ suggests the importance of the quotient $B(\mathbb{Z})\backslash\mathbb{H}$. Regarding $\mathbb{H}$ as a moduli space for triples (E,γ,γ') where E is an elliptic curve and (γ,γ') is an oriented basis for the first homology group $H_1(E,\mathbb{Z})$ of E, we see that $B(\mathbb{Z})\backslash\mathbb{H}$ parameterizes pairs (E,γ) where E is an elliptic curve and γ is a primitive element of $H_1(E,\mathbb{Z})$. To each such pair (E,γ) is naturally associated an infinite volume hyperbolic 3-manifold with boundary an elliptic curve, for the cycle γ specifies a way to fill in the surface defined by E, thus yielding a solid torus. According to a theorem of Sullivan (cf. [Sul81], [McM92]) every complete, smooth, infinite volume hyperbolic 3-manifold with boundary an elliptic curve arises in this fashion, so we consider pairs (E,C) where E is an elliptic curve over $\mathbb{C}$ and C is an oriented subgroup of E isomorphic to S^1. We call such a pair a *solid torus*; according to our discussion the quotient space $B(\mathbb{Z})\backslash\mathbb{H}$ naturally parameterizes solid tori.

For (E,C) a solid torus and $n\in\mathbb{Z}^+$ we write $C[n]$ for the group of n-division points of C, and we define an *n-compatible isogeny of solid tori* $(E',C')\to(E,C)$ to be an isogeny $E'\to E$ of elliptic curves that maps $C'[n]$ to a subgroup of $C[n]$, and we define a *fully compatible isogeny of solid tori* to be an isogeny $E'\to E$ of elliptic curves that restricts to an orientation preserving map $C'\to C$ on the underlying primitive cycles. (Note that the n in an n-compatible isogeny of solid tori does not restrict the degree of the underlying isogeny of elliptic curves.) For (E,C) a solid torus, the canonical map $E\to E/C[n]$ may be viewed as defining a fully compatible isogeny of solid tori $(E,C)\to(E,C)/C[n]$, where $(E,C)/C[n]$ is a shorthand for the solid torus whose underlying elliptic curve is $E/C[n]$, and whose primitive cycle is the image of C under the natural map $E\to E/C[n]$. It may happen that an n-compatible isogeny induces invertible n/e-compatible isogenies (i.e. *n/e-compatible isomorphisms*) $(E',C')/C'[e]\to(E,C)$ and $(E',C')\to(E,C)/C[e]$ for some divisor e of n. In this case we say that (E',C') and (E,C) are *$n+e$-related*. By considering the existence or otherwise of such morphisms of solid tori we arrive at moduli interpretations for all the $n\|h$-type groups. For example, given a subgroup S of the group of exact divisors of n, say solid tori (E,C) and (E',C') are *$n+S$-related* if (E,C) and (E',C') are $n+e$-related for some $e\in S$. Then the $n+S$-relation is an equivalence relation on solid tori, and the quotient $(\Gamma_0(n)+S)\backslash\mathbb{H}$ is in natural correspondence with $n+S$-equivalence classes of solid tori.

In this way we demonstrate that the groups of $n\|h$-type may be explained as being the groups that solve a natural family of moduli problems for decorated solid tori with conformal structure on the boundary.

1.5 Moonshine via Rademacher sums

The fact that the function (1.2.5) recovers the normalized hauptmodul of the group Γ when Γ has genus zero is a strong indication that the Rademacher sum may be useful for the purpose of understanding the functions of monstrous moonshine. A group theoretic characterization of the functions arising as McKay–Thompson series was given in [CMS04]. There the authors showed that a holomorphic function on $\mathbb{H}$ coincides with $T_g(z)$ for some $g \in \mathbb{M}$ if and only if it is the normalized hauptmodul for a group Γ satisfying each of the following properties.

1. The Riemann surface $\Gamma\backslash\mathbb{H}$ has genus zero.
2. The group Γ is of $n\|h$-type.
3. The group Γ is an extension of $\Gamma_0(nh)$ by a group of exponent 2.
4. Each cusp of Γ can be mapped to the infinite cusp by an element $\sigma \in PSL_2(\mathbb{R})$ with the property that $(\sigma\Gamma\sigma^{-1})_\infty = B(\mathbb{Z})$ and the intersection $\Gamma \cap \sigma\Gamma\sigma^{-1}$ contains $\Gamma_0(nh)$.

As we saw in §1.2 the variance of the Rademacher sum $R_\Gamma^{(-1)}(z)$ with respect to the action of Γ detects whether or not Γ has genus zero, and we have discussed in §1.4 the significance of the groups appearing in condition 2. We show in §§6.3,6.4 that the conditions 3 and 4 also admit natural reformulations in terms of the Rademacher sums.

Our reformulations come into view when we generalize the construction (1.2.2) so as to associate a Rademacher sum $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{(-1)}(z)$ to each triple $(\Gamma, \mathsf{p}, \mathsf{q})$ where Γ is a group commensurable with $PSL_2(\mathbb{Z})$, and p and q are cusps of Γ. (This construction is presented in §3.) We write $R_{\Gamma,\mathsf{p}}^{(-1)}(z)$ as a shorthand for $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{(-1)}(z)$ when q is the *infinite cusp* $\Gamma \cdot \infty$. It develops in §3.4 that $R_{\Gamma,\mathsf{p}}^{(-1)}(z)$ is an abelian integral for Γ with a simple pole at p, and no other singularities, and the expansion of $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{(-1)}(z)$ at the infinite cusp coincides with that of $R_{\Gamma,\mathsf{p}}^{(-1)}(z)$ at q, up to (addition by) a certain constant function (cf. Theorem 3.4.4). Considering all the functions $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{(-1)}(z)$ for varying cusps p and q we are able to access more subtle properties of the curve $\mathsf{X}_\Gamma = \Gamma\backslash\mathbb{H} \cup \Gamma\backslash\hat{\mathbb{Q}}$ (cf. §2.5) beyond its genus. We find in §6.3 that condition 3 translates into a certain condition of symmetry (cf. Proposition 6.3.2) in the Rademacher sums associated to the Hecke congruence group $\Gamma_0(nh)$, where n and h are as in condition 2, and we find in §6.4 that condition 4 translates into the condition (cf. Proposition 6.4.3) that the function $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{(-1)}$ be invariant for this subgroup $\Gamma_0(nh)$.

Our moduli interpretation of the $n\|h$-type groups, together with the invariance and symmetry conditions on Rademacher sums just described, facilitate a reformulation of the conditions of [CMS04]. We thus arrive at a new characterization (cf. Theorem 6.5.1) of the functions of monstrous moonshine in terms of Rademacher sums, and moduli of solid tori.

1.6 Modified Rademacher sums

In order to understand better the behavior of the Rademacher sums $R_\Gamma^{(-1)}(z)$, and, in particular, the subtraction of the constant $\mathrm{e}(-\gamma \cdot \infty)$ in (1.2.2), we consider (also in §3) a generalization of the Rademacher sum adapted to the problem of constructing modular forms of arbitrary even integer weight. Our approach to Rademacher sums of negative weight is inspired by the work of Niebur in [Nie74].

For $\kappa, m \in \mathbb{Z}$ we define the *Rademacher sum of weight* 2κ *and order* m *associated to* Γ by setting

$$R_\Gamma^{\kappa(m)}(z) = \mathrm{e}(mz) + \lim_{K\to\infty} \sum_{\gamma\in(B(\mathbb{Z})\backslash\Gamma)^\times_{\leq K}} \mathrm{e}(m\gamma\cdot z)\,\mathrm{r}^\kappa(m,\gamma,z)(cz+d)^{-2\kappa}, \tag{1.6.1}$$

where $c, d \in \mathbb{R}$ are chosen (for each summand) so that γ is the image of a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbb{R})$ in $PSL_2(\mathbb{R})$, and $\mathrm{r}^\kappa(m,\gamma,z)$ is the *Rademacher regularization factor of weight* 2κ, satisfying

$$\mathrm{r}^\kappa(m,\gamma,z) = 1 - \mathrm{e}(m\gamma\cdot\infty - m\gamma\cdot z)\,\mathrm{e}(m\gamma\cdot z - m\gamma\cdot\infty)_{<1-2\kappa}, \tag{1.6.2}$$

where $\mathrm{e}(z)_{<K}$ denotes the *partial exponential function* $\mathrm{e}(z)_{<K} = \sum_{0\leq k<K}(2\pi\mathbf{i}z)^k/k!$ (cf. §3.1). Observe that we recover the Rademacher sum $R_\Gamma^{(-1)}(z)$ of (1.2.2) when $\kappa = 0$. Also, we have $\mathrm{r}^\kappa(m,\gamma,z) = 1$ when κ is positive, so that the Rademacher sum $R_\Gamma^{\kappa(m)}(z)$ is a holomorphic Poincaré series (cf. §3.1) when $\kappa > 0$ (which is absolutely and locally uniformly convergent for $\kappa > 1$).

In §3.1 we furnish generalizations of the functions $\mathrm{Kl}_\gamma(m,n)$ and $\mathrm{Bl}_\gamma(m,n)$ for arbitrary $\kappa \in \mathbb{Z}$, obtaining a generalization of the formula (1.2.6), and leading to the following analogue (cf. Theorem 3.3.2) of (1.2.10).

$$R_\Gamma^{\kappa(m)}(z) = \mathrm{e}(mz) + \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0) + \sum_{n>0}\mathrm{c}_\Gamma^\kappa(m,n)\,\mathrm{e}(nz) \tag{1.6.3}$$

The *conjugate Rademacher sum of weight* 2κ *and order* m *associated to* Γ is defined in direct analogy with the definition (1.3.1) of the conjugate Rademacher sum $\bar{R}_\Gamma^{(-1)}(z)$, which we presently recognize as the conjugate Rademacher sum of weight 0 and order 1 associated to Γ.

$$\bar{R}_\Gamma^{\kappa(m)}(z) = \mathrm{e}(m\bar{z}) + \lim_{K\to\infty} \sum_{\gamma\in(B(\mathbb{Z})\backslash\Gamma)^\times_{\leq K}} \mathrm{e}(m\gamma\cdot\bar{z})\,\mathrm{r}^\kappa(m,\gamma,\bar{z})(c\bar{z}+d)^{-2\kappa}. \tag{1.6.4}$$

We have the following analogue of (1.3.2), and counterpart to (1.6.3), which leads naturally to analogues of (1.3.3) for arbitrary $\kappa \in \mathbb{Z}$ (cf. Theorem 3.3.3).

$$\bar{R}_\Gamma^{\kappa(m)}(z) = \mathrm{e}(m\bar{z}) - \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0) - \sum_{n<0}\mathrm{c}_\Gamma^\kappa(m,n)\,\mathrm{e}(n\bar{z}) \tag{1.6.5}$$

The variance of the functions $R_\Gamma^{\kappa(m)}(z)$ with respect to the natural (weight 2κ) action of the group Γ was described by Niebur in [Nie74] for the case that Γ has a single cusp. We verify in §4.5 that for Γ an arbitrary group commensurable with the modular group $PSL_2(\mathbb{Z})$, the function $R_\Gamma^{\kappa(m)}(z) + \mathrm{c}_\Gamma^\kappa(m,0)/2$ defines an *automorphic integral of weight* 2κ *for* Γ (cf. §2.7) when $m < 0$, meaning that $R_\Gamma^{\kappa(m)}(z)$ is holomorphic on $\mathbb{H}$, possibly having poles at cusps of Γ, and we have

$$\left(R_\Gamma^{\kappa(m)}(\gamma \cdot z) + \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0)\right)(cz+d)^{-2\kappa} = R_\Gamma^{\kappa(m)}(z) + \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0) + \omega(\gamma)(z) \tag{1.6.6}$$

for some function $\omega : \Gamma \to \mathbb{C}[z]$, where the polynomial $\omega(\gamma)(z)$ has degree at most -2κ in z (cf. Theorem 4.5.1, Proposition 4.4.10). An identification of the function ω may be given in terms of a certain canonically defined map $I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma)$, where $I_\kappa(\Gamma)$ denotes the space of automorphic integrals of weight 2κ for Γ (cf. §2.7), and $S_\kappa(\Gamma)$ denotes the space of cusp forms of weight 2κ for Γ. We show (cf. Theorem 4.5.4) that the sequence

$$0 \to M_\kappa(\Gamma) \to I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma) \to 0 \tag{1.6.7}$$

is exact, where $M_\kappa(\Gamma)$ denotes the space of modular forms of weight 2κ for Γ possibly having poles at cusps (cf. §2.7), and the map $M_\kappa(\Gamma) \to I_\kappa(\Gamma)$ is the natural inclusion.

Apart from the delicate convergence of the limit defining the Rademacher sum $R_\Gamma^{\kappa(m)}(z)$, the most curious feature of the functions $R_\Gamma^{\kappa(m)}(z)$ is that they transform naturally with respect to the group Γ only after the addition of the constant $\mathrm{c}_\Gamma^\kappa(m,0)/2$, which is typically non-zero. We overcome this feature of the classical Rademacher sum by introducing in §4 the *continued Rademacher sum of weight* 2κ *and order* m *associated to* Γ, defined for $\kappa \leq 0$ and $m < 0$ by setting

$$T_\Gamma^{\kappa(m)}(z,s) = \mathrm{e}(mz) + \sum_{\gamma \in (B(\mathbb{Z})\backslash\Gamma)^\times} \mathrm{e}(m\gamma \cdot z)\,\mathrm{t}^\kappa(m,\gamma,z,s)(cz+d)^{-2\kappa} \tag{1.6.8}$$

where $\mathrm{t}^\kappa(m,\gamma,z,s)$ is a generalization of the Rademacher regularization factor $\mathrm{r}^\kappa(m,\gamma,z)$ of (1.6.2) satisfying $\mathrm{t}^\kappa(m,\gamma,z,1) = \mathrm{r}^\kappa(m,\gamma,z)$.

The right hand side of (1.6.8) converges absolutely and locally uniformly in z and s for $z \in \mathbb{H}$ and $\Re(s) > 1$. We define $T_\Gamma^{\kappa(m)}(z)$ by taking the limit as s tends to 1 in $T_\Gamma^{\kappa(m)}(z,s)$. We find that

$$T_\Gamma^{\kappa(m)}(z) = \lim_{s\to 1^+} T_\Gamma^{\kappa(m)}(z,s) = R_\Gamma^{\kappa(m)}(z) - \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0) \tag{1.6.9}$$

(cf. Proposition 4.4.9), so that the Fourier expansion of $T_\Gamma^{\kappa(m)}(z)$ has vanishing constant term. Then, in the case that Γ has genus zero, the function $T_\Gamma^{(-1)}(z) = T_\Gamma^{0(1)}(z)$ is precisely the normalized hauptmodul of Γ. We call $T_\Gamma^{\kappa(m)}(z)$ the *normalized Rademacher sum of weight* 2κ *and order* m *associated to* Γ. We may regard the disappearance of the constant term in (1.6.9) as a consequence of the noncommutativity of the limits $s \to 1$ and $K \to \infty$ when applied to (the expression obtained by replacing $(B(\mathbb{Z})\backslash\Gamma)^\times$ with $(B(\mathbb{Z})\backslash\Gamma)^\times_{\leq K}$ in) the right hand side of (1.6.8).

To recover functions with natural modular properties at non-positive weights we modify the continued Rademacher sum by subtracting a renormalized value at $z = 0$.

$$Q_\Gamma^{\kappa(m)}(z,s) = T_\Gamma^{\kappa(m)}(z,s) - T_{0,\Gamma}^{\kappa(m)}(s) \tag{1.6.10}$$

The function $T_{0,\Gamma}^{\kappa(m)}(s)$ is defined by an expression analogous to (1.6.8) which also converges absolutely and locally uniformly in s for $\Re(s) > 1$, and would vanish at $s = 1$ if it were not for the noncommutativity of limits as $s \to 1$ and $K \to \infty$. We define the *modified Rademacher sum of weight* 2κ *and order* m *associated to* Γ, denoted $Q_\Gamma^{\kappa(m)}(z)$, by taking the limit as s tends to 1 in $Q_\Gamma^{\kappa(m)}(z,s)$, and as a counterpart to (1.6.9) we have

$$Q_\Gamma^{\kappa(m)}(z) = \lim_{s\to 1^+} Q_\Gamma^{\kappa(m)}(z,s) = R_\Gamma^{\kappa(m)}(z) + \frac{1}{2}\mathrm{c}_\Gamma^\kappa(m,0) \tag{1.6.11}$$

(cf. Proposition 4.4.10), so that, in light of (1.6.6), the modified Rademacher sum $Q_\Gamma^{\kappa(m)}(z)$ is an automorphic integral of weight 2κ for Γ.

The definition of the modified Rademacher sum $Q_\Gamma^{\kappa(m)}(z)$ is inspired by Hurwitz's relation for the Hurwitz zeta function, and our continuation procedure may be regarded as identifying the factor $1/2$, appearing in the constant term of the Fourier expansion (1.6.3) of the classical Rademacher sum of non-positive weight, with -1 times the value of the Riemann zeta function $\zeta(s)$ at $s = 0$ (cf. §4.3).

In order to obtain and analyze spanning sets for spaces of automorphic integrals we attach modified Rademacher sums $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ to each triple $(\Gamma, \mathsf{p}, \mathsf{q})$ where Γ is a group commensurable with the modular group $PSL_2(\mathbb{Z})$ and p and q are cusps of Γ (cf. §4.1). The function $Q_\Gamma^{\kappa(m)}(z)$ is then recovered upon taking both p and q to be the *infinite cusp* $\Gamma\cdot\infty$. If we write $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ as a shorthand for $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ when $\mathsf{q} = \Gamma\cdot\infty$, then, as is shown in §4.5, the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$, for varying cusps $\mathsf{p} \in \Gamma\backslash\hat{\mathbb{Q}}$ and positive integers $m \in \mathbb{Z}^+$, constitute a basis for the space $I_\kappa(\Gamma)$ when $\kappa < 0$ (cf. Theorem 4.5.3). In the case that $\kappa = 0$ the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ span a subspace of $I_0(\Gamma)$ of codimension 1, and a full basis is obtained by including a constant function. The function $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ defines an automorphic integral with a single pole at the cusp p, and the function $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ encodes the Fourier expansion of $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ at the cusp q, and no correction of constant terms is necessary for the validity of these statements.

1.7 Hecke operators

The original result of Rademacher [Rad39] identifies the first Rademacher sum $R_\Gamma^{(-1)}(z)$, for $\Gamma = PSL_2(\mathbb{Z})$, with the function $J(z) + 12$, where $J(z)$ is the normalized hauptmodul for the modular group. In light of this it is natural to try to identify more general Rademacher sums in a similar fashion. In this section we will take $\kappa = 0$, but we will allow m to be an arbitrary non-zero integer. The identity

$$R_\Gamma^{(m)}(z) = \overline{\bar{R}_\Gamma^{(-m)}(z)} \tag{1.7.1}$$

follows immediately from the definitions of the classical and conjugate Rademacher sums, demonstrating that the conjugate Rademacher sums of negative order may be recovered from the classical Rademacher sums with positive order. On the other hand, one can show, as we did for the special case that $m = -1$, that $\bar{R}_\Gamma^{(m)}(z)$ is the constant function with constant value $-\mathrm{c}_\Gamma(m, 0)/2$ in case $m < 0$ and Γ has genus zero. When $\Gamma = PSL_2(\mathbb{Z})$ we have $\mathrm{c}_\Gamma(m, 0) = 24\sigma(-m, 1)$ for $m < 0$, where $\sigma(n, 1)$ is the sum of the divisors of n, so we have the following generalization of (1.3.4) for $m < 0$.

$$\mathrm{e}(m\bar{z}) + \lim_{K\to\infty} \sum_{\substack{0<c<K \\ -K^2<d<K^2 \\ (c,d)=1}} \mathrm{e}\left(m\frac{a\bar{z}+b}{c\bar{z}+d}\right) - \mathrm{e}\left(m\frac{a}{c}\right) = -12\sigma(-m, 1) \tag{1.7.2}$$

To obtain an expression for the classical Rademacher sums $R_\Gamma^{(m)}(z)$ with negative m we can analyze again its Fourier coefficients $\mathrm{c}_\Gamma(m, n)$. It follows from our results in §6.1 that

$$\mathrm{c}_\Gamma(m, n) = \delta_{m,n} \tag{1.7.3}$$

for $m, n < 0$ in case Γ has genus zero. The resulting function $T_\Gamma^{(m)}(z) = R_\Gamma^{(m)}(z) - \mathrm{c}_\Gamma(m, 0)/2$, satisfying the identity

$$T_\Gamma^{(m)}(z) + \frac{1}{2}\mathrm{c}_\Gamma(m, 0) = \mathrm{e}(mz) + \lim_{K\to\infty} \sum_{\gamma\in(B(\mathbb{Z})\backslash\Gamma)^\times_{\leq K}} \mathrm{e}(m\gamma\cdot z) - \mathrm{e}(m\gamma\cdot\infty), \tag{1.7.4}$$

is therefore holomorphic on the upper half plane, invariant for the action of Γ, and of the form $q^{-|m|} + o(1)$ for $q = \mathrm{e}(z)$. Consequently each normalized Rademacher sum $T_\Gamma^{(-m)}(z)$, for $m > 0$, is expressible as a degree m polynomial in $T_\Gamma^{(-1)}(z) = T_\Gamma(z)$. This polynomial is none other than the so-called *m-th Faber polynomial for* $T_\Gamma(z)$.

Proceeding from another direction, we can obtain the functions $T_\Gamma^{(-m)}(z)$ from the normalized hauptmodul $T_\Gamma(z)$ by applying Hecke operators. In §5.5 we study, in particular, the case that Γ is the modular group $PSL_2(\mathbb{Z})$. Recall that for $n \in \mathbb{Z}^+$ the action of the Hecke operator $\hat{T}(n)$

on a modular function $f(z)$ may be given by setting

$$(\hat{T}(n)f)(z) = \frac{1}{n} \sum_{\substack{ad=n \\ 0\leq b<d}} f\left(\frac{az+b}{d}\right). \tag{1.7.5}$$

From this description one may deduce that the difference $T_\Gamma^{(-m)}(z) - m(\hat{T}(m)T_\Gamma)(z)$ is holomorphic in $\mathbb{H}$ and vanishes as $z \to \mathbf{i}\infty$. We thus obtain the remarkable expression

$$T_\Gamma^{(-m)}(z) = m(\hat{T}(m)T_\Gamma)(z) \tag{1.7.6}$$

for the higher order Rademacher sums which generalizes the original result of Rademacher. Combining the presentation (1.2.1) of $T_\Gamma(z)$ as a Rademacher sum with the definition (1.7.5) of the Hecke operator $\hat{T}(m)$ we obtain the expression

$$m(\hat{T}(m)T_\Gamma)(z) + \frac{1}{2}\mathrm{c}_\Gamma(-m,0) = \mathrm{e}(-mz) + \lim_{K\to\infty} \sum_{\gamma\in(B(\mathbb{Z})\backslash M(m))^\times_{\leq K}} \mathrm{e}(-\gamma\cdot z) - \mathrm{e}(-\gamma\cdot\infty), \tag{1.7.7}$$

where $M(m)$ denotes the (image in $PGL_2^+(\mathbb{Q})$ of the) set of 2×2 matrices with integral entries and determinant m. Comparison of (1.7.4) with (1.7.7), in view of the identity (1.7.6), suggests an equality of some, if not all, exponential terms in both sums, and in fact there is an injective map

$$\begin{aligned} B(\mathbb{Z})\backslash M(1) &\hookrightarrow B(\mathbb{Z})\backslash M(m) \\ \gamma &\mapsto \tilde{\gamma}, \end{aligned} \tag{1.7.8}$$

since $M(1) = \Gamma$ when $\Gamma = PSL_2(\mathbb{Z})$, with the property that $\mathrm{e}(-m\gamma\cdot z) = \mathrm{e}(-\tilde{\gamma}\cdot z)$. In the case that m is prime, the remaining terms assemble into a fractional power Rademacher sum

$$\mathrm{e}\left(-\frac{1}{m}z\right) + \lim_{K\to\infty} \sum_{\gamma\in(B(m\mathbb{Z})\backslash\Gamma)^\times_{\leq K}} \mathrm{e}\left(-\frac{1}{m}\gamma\cdot z\right) - \mathrm{e}\left(-\frac{1}{m}\gamma\cdot\infty\right), \tag{1.7.9}$$

where $B(m\mathbb{Z})$ is the *m-fold translation group*, generated by $z \mapsto z+m$. Thus we obtain another injective correspondence

$$\begin{aligned} B(m\mathbb{Z})\backslash M(1) &\hookrightarrow B(\mathbb{Z})\backslash M(m) \\ \gamma &\mapsto \tilde{\gamma} \end{aligned} \tag{1.7.10}$$

with the property that $\mathrm{e}(-\gamma\cdot z/m) = \mathrm{e}(-\tilde{\gamma}\cdot z)$. The identity (1.7.7) implies the vanishing of the fractional power Rademacher sum (1.7.9). This can also be proven directly, and we give a general vanishing result for fractional Rademacher sums in §5.4. More generally we obtain fractional power sums of the form

$$\mathrm{e}\left(-\frac{m}{l^2}z\right)+\lim_{K\to\infty}\sum_{\gamma\in(B(l\mathbb{Z})\backslash\Gamma)^{\times}_{\leq K}}\mathrm{e}\left(-\frac{m}{l^2}\gamma\cdot z\right)-\mathrm{e}\left(-\frac{m}{l^2}\gamma\cdot\infty\right), \tag{1.7.11}$$

for each exact divisor l of m, and each of these fractional power sums vanishes except for the sum corresponding to $l=1$. Thus our analysis covers generalizations of the Rademacher sums to fractional orders in addition to the higher integral orders. All the results discussed in this section admit generalizations to arbitrary groups commensurable with the modular group but we restrict ourselves to the modular group in this article.

1.8 Monstrous Lie algebras

The presentation (1.7.6) of the functions $T_\Gamma^{(-m)}(z)$ by means of Hecke operators (we restrict to the case $\Gamma=PSL_2(\mathbb{Z})$ in §1.7) immediately implies that their Fourier coefficients are positive integers. This fact points to the existence of further algebraic structures beyond the moonshine module vertex operator algebra $V^\natural$. In his proof of the moonshine conjectures [Bor92] Borcherds introduced the Monster Lie algebra $\mathfrak{m}$, which admits a presentation as a bi-graded generalized Kac–Moody algebra. The key to Borcherds' method is the denominator identity for $\mathfrak{m}$. This in turn can be interpreted as a BGG-type resolution of the trivial $\mathfrak{m}$-module. Let $\mathcal{V}$ denote the Verma module with highest weight 0 for $\mathfrak{m}$. Then $\mathcal{V}$ is the first term in this BGG-type resolution of the trivial module, and the bi-graded dimension $\operatorname{gdim}\mathcal{V}$ of $\mathcal{V}$ is obtained by computing the coefficients of p and q in the expression

$$\operatorname{gdim}\mathcal{V}=\exp\left(\sum_{m>0}(\hat{T}(m)T_\Gamma)(z)p^m\right) \tag{1.8.1}$$

where $q=\mathrm{e}(z)$. Applying the operator $F\mapsto p\partial_p\log F$ to (1.8.1) we obtain a generating function for the higher (absolute) order normalized Rademacher sums $T_\Gamma^{(-m)}(z)$, by (1.7.6). It is well-known (cf. [Mac95]) that this operator relates the complete homogeneous symmetric functions to the power-sum symmetric functions. Thus the bi-graded dimension of the Verma module for the Monster Lie algebra may be viewed as the *complete Rademacher sum* (of weight 0) associated to Γ.

In §7.2 we consider a family of generalized Kac–Moody algebras $\{\mathfrak{m}_g\}$, indexed by elements g in the Monster group $\mathbb{M}$. Just as the Monster Lie algebra may be constructed from the moonshine module $V^\natural$, the monstrous Lie algebras $\mathfrak{m}_g$, studied by Carnahan in [Car07], may be constructed from the g-twisted $V^\natural$-modules $V^\natural_g$, for $g\in\mathbb{M}$. The graded dimensions of the spaces

$V_g^\natural$ are given by functions $J_g(z) = J_{\Gamma_g}(z)$, related to the McKay–Thompson series $T_g(z)$ via the involution $z \mapsto -1/z$.

$$J_g(z) = T_g(-1/z) \tag{1.8.2}$$

One should note that Borcherds set the precedent here, introducing a family $\{\mathfrak{m}'_g\}$ of monstrous Lie superalgebras in [Bor92]. These algebras $\mathfrak{m}'_g$ are more directly related to the functions $T_g(z)$, rather than the $J_g(z)$, and for our purposes the algebras $\mathfrak{m}_g$ appear to be more convenient.

The monstrous Lie algebras $\mathfrak{m}_g$ are constructed in [Car07] using the semi-infinite cohomology version of the no-ghost theorem. We identify the bi-graded subspaces of the algebra $\mathfrak{m}_g$ in terms of the twisted modules $V_h^\natural$, with $h \in \langle g \rangle$. One can show that the $\mathfrak{m}_g$ are generalized Kac–Moody algebras, and one can also deduce formulas for the bi-graded dimensions of their Verma modules $\mathcal{V}_g$, generalizing (1.8.1).

$$\operatorname{gdim} \mathcal{V}_g = \exp\left(\sum_{m>0} (\hat{T}(m)T_g)(z)p^m \right) \tag{1.8.3}$$

Carnahan [Car07] also found a remarkable denominator identity which yields an alternative expression for the graded dimension of $\mathcal{V}_g$; namely,

$$\operatorname{gdim} \mathcal{V}_g = \frac{1}{p(T_g(w) - J_g(z))} \tag{1.8.4}$$

where $p = \mathrm{e}(w)$. This identity (1.8.4) demonstrates that the bi-graded dimension can be viewed as a meromorphic function on $\mathbb{H} \times \mathbb{H}$ with poles at $w \in \Gamma_g \cdot (-1/z)$.

We also show in §7.2 that the bi-graded dimension of $\mathcal{V}_g$ is bounded below, coefficient-wise, by the generating function

$$\sum_{m>0} J_g^{(-m)}(z)p^m \tag{1.8.5}$$

where $J_g^{(-m)}(z) = T_g^{(-m)}(-1/z)$ when g is of Fricke type (cf. Proposition 7.2.4). This suggests that the Verma modules $\mathcal{V}_g$ may contain naturally defined subspaces whose bi-graded dimensions coincide with the expressions (1.8.5).

1.9 Chiral gravity

Our results on Rademacher sums, at first glance, add as much to the mystery of monstrous moonshine as they reveal. We have formulated a characterization of the groups of monstrous moonshine in terms of Rademacher sums and solid tori. Having done so we face the new question of where the Rademacher sums themselves appear in relation to the moonshine module vertex operator algebra $V^\natural$? It appears now that the relation to physics should again be useful, as it was in the construction of $V^\natural$ [FLM88], and the proof of the moonshine conjecture [Bor92].

In §7.1 we explain how the Rademacher sums associated to elements of the Monster might be regarded as giving strong evidence for the existence of another construction of the moonshine module $V^\natural$, and its twisted sectors $V_g^\natural$, in which all the features of monstrous moonshine, including the genus zero property, become transparent. In fact the original Rademacher sum (1.2.1) does appear as a saddle point approximation to the partition function of the simplest chiral three dimensional quantum gravity. (See [Wit07], [MW07], [Man07], [MM07], [LSS08] and [MSS09] for the development of this idea in the physics literature.) Our new identity (1.3.4) for the conjugate Rademacher sum must reflect the chiral nature of this three dimensional quantum gravity.

We expect that our analytic continuation of the Rademacher sums, and the explanation of the appearance of the constant term, will also develop from a rigorous analysis of the saddle point approximation using a zeta function regularization of the chiral gravity partition function, as was done for various models of two dimensional CFT. Our analysis of the Rademacher sums corresponding to the discrete groups of monstrous moonshine, and of moduli spaces of decorated solid tori points to a description of all the spaces $V_g^\natural$, for $g \in \mathbb{M}$, via a family of g-twisted versions of the simplest chiral three dimensional quantum gravity. We expect that our reformulation of monstrous moonshine in terms of Rademacher sums and moduli of solid tori will eventually be understood from the properties of this remarkable chiral three dimensional quantum gravity.

In §7.3 we also elucidate the relationship between the higher order Rademacher sums, and the key object of Borcherds' proof of the moonshine conjecture; viz., the Monster Lie algebra, and its twisted counterparts. This leads us to the stringy quantization (cf. [DMVV97]) of $V^\natural$, and we generalize this to all twisted sectors $V_g^\natural$, for $g \in \mathbb{M}$. We prove in Theorem 7.3.1 that the resulting second quantized spaces have the same bi-graded dimensions as the Verma modules $\mathcal{V}_g$ (cf. (1.8.3)) and thus may be viewed as stringy realizations of the representations of the generalized Kac–Moody algebras $\mathfrak{m}_g$. It is an interesting problem to interpret the spaces $\mathcal{V}_g$, and their subspaces with graded dimension given by the higher order normalized Rademacher sums (1.8.5), in terms of the second quantized chiral three dimensional quantum gravities. In particular, the simple description of the singularities of the partition function given by (1.8.4) should have a natural interpretation in terms of quantum gravity.

Thus our present results on the Rademacher sums, and the new conjectures about their origin, clearly indicate that the real nature of moonshine might not be as remote anymore, and more than this, the full examination of its structure might give new insight into the fundamental problem of modern physics.

2 Conventions

We write $\mathbb{Z}^+$ for the set of positive integers, and the notations $\mathbb{Q}^+$ and $\mathbb{R}^+$ are to be interpreted similarly. We write $\mathbb{N}$ for the set of non-negative integers. For R a ring without zero divisors, we write $R^\times$ for the multiplicative monoid of non-zero elements in R.

2.1 Functions

For $z, s \in \mathbb{C}$ with $z \neq 0$, we write z^s as a shorthand for $\exp(s\log(z))$, where log denotes the principal branch of the logarithm, so that

$$-\pi < \Im(\log(z)) \leq \pi, \tag{2.1.1}$$

and we write $z^{(s)}$ as a shorthand for $z^s/\Gamma(s+1)$, where $\Gamma(s)$ denotes the Gamma function. We adopt the convention of setting

$$\mathrm{e}(z) = \exp(2\pi\mathbf{i}z) = \sum_{k\geq 0}(2\pi\mathbf{i}z)^{(k)} \tag{2.1.2}$$

for $z \in \mathbb{C}$. We write $\Phi(a, b, z)$ for the analytic function on $\mathbb{C}^3$ defined by setting

$$\Phi(a, b, z) = \frac{{}_1F_1(a; b; 2\pi\mathbf{i}z)}{\Gamma(b)} = \sum_{k\geq 0}\frac{\Gamma(k+a)}{\Gamma(a)\Gamma(k+b)}(2\pi\mathbf{i}z)^{(k)} \tag{2.1.3}$$

where ${}_1F_1(a; b; x)$ denotes the confluent hypergeometric function (cf. [AS64, §13]). Kummer's transformations for the confluent hypergeometric function yield the following identity for Φ.

$$\Phi(a, b, z) = \mathrm{e}(z)\Phi(b-a, b, -z) \tag{2.1.4}$$

The exponential function $\mathrm{e}(z)$ is a solution to the differential equation

$$(z\partial_z + 1 - s)(\partial_z - 2\pi\mathbf{i})u(z) = 0, \tag{2.1.5}$$

which has a regular singular point at 0 and an irregular singularity at ∞. Another solution is furnished by the function $z \mapsto \Phi(1, 1+s, z)(2\pi\mathbf{i}z)^s$, which we denote also by $\mathrm{e}(z, s)$.

$$\mathrm{e}(z, s) = \Phi(1, 1+s, z)(2\pi\mathbf{i}z)^s = \sum_{k\geq 0}(2\pi\mathbf{i}z)^{(k+s)} \tag{2.1.6}$$

Observe that we have $\mathrm{e}(z, n) = \mathrm{e}(z) - \mathrm{e}(z)_{<n}$ for $n \in \mathbb{Z}$, where $\mathrm{e}(z)_{<K}$ denotes the *partial exponential* $\mathrm{e}(z)_{<K} = \sum_{0\leq k<K}(2\pi\mathbf{i}z)^{(k)}$. In particular, $\mathrm{e}(z, n) = \mathrm{e}(z)$ when $n \leq 0$.

2.2 Divisors

For $n \in \mathbb{Z}^+$ and $s \in \mathbb{C}$ we write $\sigma(n,s)$ for the *divisor function*

$$\sigma(n,s) = \sum_{d|n} d^s. \tag{2.2.1}$$

For $a, b \in \mathbb{Z}$ we write (a,b) for the greatest common divisor of a and b, and we generalize this notation by writing $((a,b)$ for the greatest positive integer c say, such that $c^2|a$ and $c|b$, and by writing (a^∞, b) for the largest divisor of b that divides some power of a.

$$((a,b) = \max\left\{c \in \mathbb{Z}^+ \mid c^2|a \text{ and } c|b\right\} \tag{2.2.2}$$

$$(a^\infty, b) = \lim_{n\to\infty} (a^n, b) \tag{2.2.3}$$

For $d, n \in \mathbb{Z}^+$ we write $d\|n$ in the case that $d|n$ and $(d, n/d) = 1$, and call such a d an *exact divisor of* n. We write $\mathrm{Ex}(n)$ for the set of exact divisors of n. Then $\mathrm{Ex}(n)$ becomes a group of exponent 2 when equipped with the product $(e,f) \mapsto ef/(e,f)^2$. Indeed, if we write $\Pi(n)$ for the set of primes that divide n then there is a naturally defined isomorphism $\mathrm{Ex}(n) \cong (\mathbb{Z}/2)^{\Pi(n)}$ which associates to an exact divisor $e \in \mathrm{Ex}(n)$ the indicator function $\chi_e : \Pi(n) \to \mathbb{Z}/2$, satisfying $\chi_e(p) = 1$ if $p|e$ and $\chi_e(p) = 0$ otherwise.

Let Π denote the set of all primes. Then the infinite product $(\mathbb{Z}/2)^\Pi$ comes equipped with a naturally defined projection $(\mathbb{Z}/2)^\Pi \to (\mathbb{Z}/2)^{\Pi(n)}$, and a naturally defined section for it $(\mathbb{Z}/2)^{\Pi(n)} \to (\mathbb{Z}/2)^\Pi$, for each $n \in \mathbb{Z}^+$. Consequently we have naturally defined morphisms of groups $(\mathbb{Z}/2)^\Pi \to \mathrm{Ex}(n)$ and $\mathrm{Ex}(n) \to (\mathbb{Z}/2)^\Pi$ for each n, and for any $m, n \in \mathbb{Z}^+$ we have the natural map $\mathrm{Ex}(m) \to \mathrm{Ex}(n)$ furnished by the composition $\mathrm{Ex}(m) \to (\mathbb{Z}/2)^\Pi \to \mathrm{Ex}(n)$. If m divides n then the map $\mathrm{Ex}(m) \to \mathrm{Ex}(n)$ is injective, the map $\mathrm{Ex}(n) \to \mathrm{Ex}(m)$ is surjective, and the composition $\mathrm{Ex}(m) \to \mathrm{Ex}(n) \to \mathrm{Ex}(m)$ is the identity on $\mathrm{Ex}(m)$.

2.3 Isometries

Let us write $G(\mathbb{R})$ for the simple real Lie group $PSL_2(\mathbb{R})$. The group $G(\mathbb{R})$ acts naturally, from the left, on the upper-half plane $\mathbb{H} = \{z \in \mathbb{C} \mid \Im(z) > 0\}$, and is just the group of orientation preserving isometries of $\mathbb{H}$ when we equip it with the *hyperbolic measure* $\mathrm{d}\mu(z) = \mathrm{d}x\mathrm{d}y/y^2$, for $z = x + \mathbf{i}y$.

It is convenient to enlist matrices in $SL_2(\mathbb{R})$ for the purpose of specifying elements of $G(\mathbb{R})$. We write $\left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$ for the image of a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbb{R})$ in $G(\mathbb{R})$. Analogously, we write $A \mapsto [A]$ for the canonical map $SL_2(\mathbb{R}) \to G(\mathbb{R})$. The action of $G(\mathbb{R})$ on $\mathbb{H}$ is now described explicitly by the formula

$$\gamma \cdot z = \frac{az+b}{cz+d} \tag{2.3.1}$$

for $\gamma = \left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$. The matrix $\theta = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \in GL_2(\mathbb{R})$ induces an outer-automorphism of $G(\mathbb{R})$, which we call *conjugation on* $G(\mathbb{R})$, and which we denote $\gamma \mapsto \bar{\gamma}$. Explicitly, we have

$$\bar{\gamma} = \begin{bmatrix} -a & b \\ c & -d \end{bmatrix} \Longleftarrow \gamma = \begin{bmatrix} a & b \\ c & d \end{bmatrix}. \tag{2.3.2}$$

For each matrix $A \in GL_2^+(\mathbb{Q})$ there is a unique $\mu \in \mathbb{R}^+$ for which $A' = \mu A$ belongs to $SL_2(\mathbb{R})$. The assignment $GL_2^+(\mathbb{Q}) \to G(\mathbb{R})$ given by $A \mapsto [A']$ then factors through $PGL_2^+(\mathbb{Q})$, and the resulting map $PGL_2^+(\mathbb{Q}) \to G(\mathbb{R})$ is an embedding of groups. We write $G(\mathbb{Q})$ for the copy of $PGL_2^+(\mathbb{Q})$ in $G(\mathbb{R})$ obtained in this way. We write $G(\mathbb{Z})$ for the *modular group* $PSL_2(\mathbb{Z})$.

Extending the notation introduced above, we write $[A]$ and $\left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$ for the image in $G(\mathbb{Q}) < G(\mathbb{R})$ of a matrix $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ in $GL_2^+(\mathbb{Q})$. Given $\mu \in \mathbb{Q}^+$ we write $[\mu]$ as a shorthand for $[A]$ when A is the diagonal matrix $\left(\begin{smallmatrix} \mu & 0 \\ 0 & 1 \end{smallmatrix}\right)$. Then $[\mu] \cdot z = \mu z$ for $z \in \mathbb{H}$.

$$[\mu] = \begin{bmatrix} \mu & 0 \\ 0 & 1 \end{bmatrix} \tag{2.3.3}$$

Let $B(\mathbb{R})$ denote the Borel subgroup of $G(\mathbb{R})$ consisting of images of upper-triangular matrices in $SL_2(\mathbb{R})$, so that $B(\mathbb{R})$ is just the subgroup of $G(\mathbb{R})$ that fixes the distinguished point ∞ on the *pointed real projective line* $\hat{\mathbb{R}} = \mathbb{R} \cup \{\infty\}$. Let $B(\mathbb{Q})$ and $B(\mathbb{Z})$ denote the intersections $B(\mathbb{R}) \cap G(\mathbb{Q})$ and $B(\mathbb{R}) \cap G(\mathbb{Z})$, respectively. Then $B(\mathbb{Z})$ is the group generated by the *modular translation* $T = \left[\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right]$. Set $\hat{\mathbb{Q}} = \mathbb{Q} \cup \{\infty\} \subset \hat{\mathbb{R}}$. Then $G(\mathbb{Q})$ acts naturally on $\hat{\mathbb{Q}}$, and $B(\mathbb{Q})$ is just the subgroup of $G(\mathbb{Q})$ that fixes the point ∞. For $\alpha \in \mathbb{Q}$ we write T^α for the element $\left[\begin{smallmatrix} 1 & \alpha \\ 0 & 1 \end{smallmatrix}\right] \in B(\mathbb{Q})$.

$$T^\alpha = \begin{bmatrix} 1 & \alpha \\ 0 & 1 \end{bmatrix} \tag{2.3.4}$$

Then the elements of $B(\mathbb{Q})$ of the form T^α for $\alpha \in \mathbb{Q}$ constitute the *unipotent subgroup of* $B(\mathbb{Q})$, which we denote $B_u(\mathbb{Q})$. Given $\alpha \in \mathbb{Q}^+$ we write $B(\alpha\mathbb{Z})$ for the subgroup of $B_u(\mathbb{Q})$ generated by T^α.

$$B(\alpha\mathbb{Z}) = \left\{ \begin{bmatrix} 1 & \alpha n \\ 0 & 1 \end{bmatrix} \mid n \in \mathbb{Z} \right\} \tag{2.3.5}$$

The elements of $B(\mathbb{Q})$ of the form $[\mu]$ for $\mu \in \mathbb{Q}^+$ constitute the *diagonal subgroup of* $B(\mathbb{Q})$, which we denote $B_d(\mathbb{Q})$. The group $B(\mathbb{Q})$ is naturally isomorphic to the semidirect product $B_u(\mathbb{Q}) \rtimes B_d(\mathbb{Q})$. In particular, $B_u(\mathbb{Q})$ is a normal subgroup of $B(\mathbb{Q})$ and for any $\chi \in B(\mathbb{Q})$ we have $\chi = T^{\alpha}[\mu]$ for some uniquely determined $\alpha \in \mathbb{Q}$ and $\mu \in \mathbb{Q}^+$.

An element $\gamma \in G(\mathbb{Q})$ will have many preimages in $GL_2^+(\mathbb{Q})$, but among these there will be exactly two that have integral entries with no common divisor. Either of these two matrices will be called a *preferred representative* for γ. We define functions $P\det : G(\mathbb{Q}) \to \mathbb{Z}^+$ and $c : G(\mathbb{Q}) \to \mathbb{N}$ and $d : G(\mathbb{Q}) \to \mathbb{N}$ by setting

$$P\det(\gamma) = ad - bc, \quad c(\gamma) = |c|, \quad d(\gamma) = |d|, \tag{2.3.6}$$

in case $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in GL_2^+(\mathbb{Q})$ is a preferred representative for γ. We call $P\det$ the *projective determinant.* The group $G(\mathbb{Z})$ is exactly the preimage of 1 with respect to the projective determinant. The projective determinant is not multiplicative, but we have $P\det(\gamma\sigma) = P\det(\sigma) = P\det(\sigma\gamma)$ for all $\sigma \in G(\mathbb{Q})$ in case $P\det(\gamma) = 1$, so for any $n \in \mathbb{Z}^+$ the preimage of n under $P\det$ admits commuting left and right actions of $G(\mathbb{Z})$.

Observe that $c(T\gamma) = c(\gamma T) = c(\gamma)$ and $d(T\gamma) = d(\gamma)$. Given $X \subset G(\mathbb{Q})$ we set $X_\infty = X \cap B(\mathbb{Q})$ and $X^\times = X - X_\infty$. Then $X_\infty = \{\chi \in X \mid c(\chi) = 0\}$. We define $X^{\times\times}$ to be the subset of $X^\times$ consisting of $\chi \in X$ such that both $c(\chi)$ and $d(\chi)$ are non-zero.

$$X_\infty = \{\chi \in X \mid c(\chi) = 0\}\,, \tag{2.3.7}$$

$$X^\times = \{\chi \in X \mid c(\chi) \neq 0\}\,, \quad X^{\times\times} = \{\chi \in X \mid c(\chi)d(\chi) \neq 0\} \tag{2.3.8}$$

For $\gamma \in G(\mathbb{Q})$ with $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ a preferred representative, we have

$$\gamma \cdot z - \gamma \cdot z' = \frac{P\det(\gamma)}{(cz+d)(cz'+d)}(z - z') \tag{2.3.9}$$

for $z, z' \in \mathbb{H}$, so that the derivative of the function $z \mapsto \gamma \cdot z$, which we will denote $\mathrm{jac}(\gamma, z)$, is given by

$$\mathrm{jac}(\gamma, z) = \frac{P\det(\gamma)}{(cz+d)^2}. \tag{2.3.10}$$

Note that the assignment $\mathrm{jac} : G(\mathbb{Q}) \to \mathcal{O}(\mathbb{H})$, which associates the function $z \mapsto \mathrm{jac}(\gamma, z)$ to an element $\gamma \in G(\mathbb{Q})$, descends naturally to the coset space $B(\mathbb{Z})\backslash G(\mathbb{Q})$, and even further to $B_u(\mathbb{Q})\backslash G(\mathbb{Q})$.

From (2.3.9) and (2.3.10) we see that $|\gamma \cdot z - \gamma \cdot z'| = |z - z'|$ just in the case that z and z' belong to the set $\{z \in \mathbb{H} \mid |\mathrm{jac}(\gamma, z)| = 1\}$ which we call the *isometric locus of* γ. The isometric locus of γ is a (Euclidean) semicircle just when $c(\gamma) > 0$, in which case its center is $\gamma^{-1} \cdot \infty$, and its radius is $\sqrt{\varrho(\gamma)}$, where

$$\varrho(\gamma)=\frac{P\det(\gamma)}{c(\gamma)^2}=\frac{ad-bc}{c^2} \tag{2.3.11}$$

in case $\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right)$ is a preferred representative for γ. We call $\varrho(\gamma)$ the *scaling factor* associated to γ.

2.4 Cosets

Given a subset $X\subset G(\mathbb{Q})$, we will write $\llbracket X\rrbracket$ for the set consisting of double cosets of the form $B(\mathbb{Z})\chi B(\mathbb{Z})$, for $\chi\in X$. We will write $\llbracket\chi\rrbracket$ as a shorthand for the particular double coset $B(\mathbb{Z})\chi B(\mathbb{Z})$.

$$\llbracket\chi\rrbracket=B(\mathbb{Z})\chi B(\mathbb{Z}),\quad \llbracket X\rrbracket=\{\llbracket\chi\rrbracket\in B(\mathbb{Z})\backslash G(\mathbb{Q})/B(\mathbb{Z})\mid\chi\in X\} \tag{2.4.1}$$

Similarly, we will write $\llbracket X$ for the set of right cosets of the form $B(\mathbb{Z})\chi$, for $\chi\in X$, and $\chi\mapsto\llbracket\chi$ will denote the natural map $X\to\llbracket X$, and the notations $X\rrbracket$ and $\chi\mapsto\chi\rrbracket$ will have the analogous meanings. Observe that $B(\mathbb{Z})$ is stable under the operations of inversion and conjugation (cf. (2.3.2)), and thus these operations descend naturally to the coset spaces $\llbracket G(\mathbb{Q})$ and $G(\mathbb{Q})\rrbracket$ and $\llbracket G(\mathbb{Q})\rrbracket$.

Recall from §2.3 that the assignment $\chi\mapsto\operatorname{jac}(\chi,z)$ descends to a well-defined association of holomorphic functions on $\mathbb{H}$ to right cosets of $B(\mathbb{Z})$ in $G(\mathbb{Q})$. Accordingly, we may safely set $\operatorname{jac}(\llbracket\chi\,,z)=\operatorname{jac}(\chi,z)$, when given some $\llbracket\chi\in\llbracket G(\mathbb{Q})$.

$$\begin{aligned}\operatorname{jac}(\cdot\,,z):\llbracket G(\mathbb{Q})&\to\mathcal{O}(\mathbb{H})\\ \llbracket\chi&\mapsto\operatorname{jac}(\llbracket\chi\,,z)\end{aligned} \tag{2.4.2}$$

Given $U\subset\llbracket G(\mathbb{Q})$ or $S\subset\llbracket G(\mathbb{Q})\rrbracket$ we set $U_\infty=U\cap\llbracket B(\mathbb{Q})$ and $U^\times=U-U_\infty$, and similarly, $S_\infty=S\cap\llbracket B(\mathbb{Q})\rrbracket$ and $S^\times=S-S_\infty$. In particular, $\llbracket G(\mathbb{Q})\rrbracket^\times$ denotes the set of double cosets $\llbracket\chi\rrbracket$, for $\chi\in G(\mathbb{Q})$, for which $c(\chi)\neq 0$.

Observe that the isometric loci (cf. §2.3) associated to $\chi,\chi'\in G(\mathbb{Q})$ coincide when $\llbracket\chi=\llbracket\chi'$. Thus we may regard these loci as naturally attached to right cosets of $B(\mathbb{Z})$ in $G(\mathbb{Q})$, and the locus attached to $\llbracket\chi$ is a Euclidean semicircle just when $\llbracket\chi\in\llbracket G(\mathbb{Q})^\times$. Also, the loci associated to cosets $\llbracket\chi\,,\llbracket\chi'\in\llbracket G(\mathbb{Q})^\times$ have the same radii when $\llbracket\chi\rrbracket=\llbracket\chi'\rrbracket$; that is to say, the function ϱ of (2.3.11) descends to a well-defined map $\llbracket G(\mathbb{Q})\rrbracket^\times\to\mathbb{Q}^+$. It is worth noting that the function $\chi\mapsto\varrho(\chi)$ actually satisfies an even stronger invariance condition.

Lemma 2.4.1. *The assignment $\llbracket\chi\rrbracket\mapsto\varrho\llbracket\chi\rrbracket$ descends naturally to a well-defined function on the double coset space $B_u(\mathbb{Q})\backslash G(\mathbb{Q})/B_u(\mathbb{Q})$. That is, we have $\varrho\llbracket T^\alpha\chi\rrbracket=\varrho\llbracket\chi T^\alpha\rrbracket=\varrho\llbracket\chi\rrbracket$ for any $\alpha\in\mathbb{Q}$ and $\chi\in G(\mathbb{Q})^\times$.*

The function ϱ is also invariant under inversion and conjugation, so that we have $\varrho\llbracket\chi\rrbracket = \varrho\llbracket\bar{\chi}\rrbracket = \varrho\left\llbracket\chi^{-1}\right\rrbracket$ for any $\chi \in G(\mathbb{Q})^{\times}$. For $\chi \in G(\mathbb{Q})^{\times}$ the identity (2.3.9) may be rewritten

$$\chi \cdot z - \chi \cdot z' = \frac{\varrho\llbracket\chi\rrbracket}{(z - \chi^{-1}\cdot\infty)(z' - \chi^{-1}\cdot\infty)}\,(z - z'), \tag{2.4.3}$$

and we may consider the limit as $z' \to \infty$, which yields a useful expression for $\chi \cdot z - \chi \cdot \infty$; viz.,

$$\chi \cdot z - \chi \cdot \infty = -\frac{\varrho\llbracket\chi\rrbracket}{z - \chi^{-1}\cdot\infty}. \tag{2.4.4}$$

Comparing with (2.3.10) and (2.4.4) we have

$$\mathrm{jac}(\llbracket\chi\,, z) = \frac{\varrho\llbracket\chi\rrbracket}{(z - \chi^{-1}\rrbracket\cdot\infty)^2} \tag{2.4.5}$$

for $\llbracket\chi \in \llbracket G(\mathbb{Q})^{\times}$ (and $\mathrm{jac}(\llbracket\chi\,, z) = 1$ otherwise).

The functions $c, d : G(\mathbb{Q}) \to \mathbb{N}$, of §2.3, descend to well-defined functions on the coset space $\llbracket G(\mathbb{Q}) = B(\mathbb{Z})\backslash G(\mathbb{Q})$. The function c descends further, to be well-defined on the double coset space $\llbracket G(\mathbb{Q})\rrbracket = B(\mathbb{Z})\backslash G(\mathbb{Q})/B(\mathbb{Z})$. For $K \in \mathbb{R}^+$ and U a subset of $\llbracket G(\mathbb{Q})$, define $U_{\leq K}$ to be the subset of U consisting of cosets $\llbracket\chi \in U$ for which $c(\chi) \leq K$ and $d(\chi) \leq K^2$. Analogously, for S a subset of $\llbracket G(\mathbb{Q})\rrbracket$, define $S_{\leq K}$ to be the subset of S consisting of double cosets $\llbracket\chi\rrbracket \in S$ for which $c(\chi) \leq K$.

$$U_{\leq K} = \left\{\llbracket\chi \in U \mid c(\chi) \leq K,\, d(\chi) \leq K^2\right\} \tag{2.4.6}$$

$$S_{\leq K} = \{\llbracket\chi\rrbracket \in S \mid c(\chi) \leq K\} \tag{2.4.7}$$

2.5 Groups

The group $G(\mathbb{Q})$ is the commensurator of $G(\mathbb{Z})$. Consequently, any group $\Gamma < G(\mathbb{R})$ that is commensurable with the modular group $G(\mathbb{Z})$ is automatically a subgroup of $G(\mathbb{Q})$, and is an example of a Fuchsian group of the first kind. For such a group Γ there is a natural way to equip the orbit space $\Gamma\backslash\mathbb{H}$ with the structure of a Riemann surface; we will denote this object by Y_Γ. Any group Γ commensurable with $G(\mathbb{Z})$ has parabolic elements, and any fixed point of any parabolic element of Γ lies on the (pointed) rational projective line $\hat{\mathbb{Q}} \subset \hat{\mathbb{R}}$. The orbit space $\mathsf{P}_\Gamma = \Gamma\backslash\hat{\mathbb{Q}}$ is the set of *cusps of* Γ. For Γ commensurable with $G(\mathbb{Z})$, the Riemann surface Y_Γ is not compact, but can be compactified in a natural way by adjoining a single point for each cusp of Γ. We will write X_Γ for the corresponding compact Riemann surface obtained by the adjunction of the cusps of Γ.

$$\mathsf{X}_\Gamma = \mathsf{Y}_\Gamma \cup \mathsf{P}_\Gamma = \Gamma\backslash\mathbb{H} \cup \Gamma\backslash\hat{\mathbb{Q}} \tag{2.5.1}$$

We will say that Γ is a *group of genus zero* in the case that X_Γ has genus zero as a Riemann surface. We set $\operatorname{genus}(\Gamma) = \operatorname{genus}(\mathsf{X}_\Gamma)$ for $\Gamma < G(\mathbb{R})$ commensurable with $G(\mathbb{Z})$.

We write $\hat{\mathbb{C}}$ for the *(pointed) complex projective line* $\mathbb{C} \cup \{\infty\}$, which we regard as a compact Riemann surface in the usual way. If Γ is a group for which the compact Riemann surface X_Γ has genus zero, then there is an isomorphism $\phi : \mathsf{X}_\Gamma \xrightarrow{\sim} \hat{\mathbb{C}}$ that witnesses this fact, and the set of such isomorphisms admits a simply transitive action by $G(\mathbb{C})$. Thus we may assume that ϕ maps the point of X_Γ corresponding to the *infinite cusp* $\Gamma \cdot \infty$ to the distinguished point $\infty \in \hat{\mathbb{C}}$. Such an isomorphism ϕ determines a Γ-invariant holomorphic function, f say, on $\mathbb{H}$, which admits an expression $f(z) = \sum_{n \geq -1} c(n/h)\,\mathrm{e}(nz/h)$ with $c(-1/h) \neq 0$ for some positive integer h called the *width of* Γ *at infinity*. After multiplying by $1/c(-1/h)$ we may assume that $c(-1/h) = 1$. A Γ-invariant function of the form $\mathrm{e}(-z/h) + \sum_{n \geq 0} c(n/h)\,\mathrm{e}(nz/h)$ which is holomorphic on $\mathbb{H}$ and induces an isomorphism $\mathsf{X}_\Gamma \xrightarrow{\sim} \hat{\mathbb{C}}$ will be called a *hauptmodul* for Γ. In case $c(0) = 0$ we say that f is a *normalized hauptmodul* for Γ.

The *Hecke congruence groups*, denoted $\Gamma_0(n)$ for $n \in \mathbb{Z}^+$, play a special rôle in our analysis.

$$\Gamma_0(n) = \left\{ \begin{bmatrix} a & b \\ cn & d \end{bmatrix} \mid a, b, c, d \in \mathbb{Z},\ ad - bcn = 1 \right\} \tag{2.5.2}$$

According to [CN79] the normalizer $N(\Gamma_0(n))$ of $\Gamma_0(n)$ in $G(\mathbb{R})$ is commensurable with $G(\mathbb{Z})$ and admits the description

$$N(\Gamma_0(n)) = \left\{ \begin{bmatrix} ae & b/h \\ cn/h & de \end{bmatrix} \mid a, b, c, d \in \mathbb{Z},\ e \in \mathbb{Z}^+,\ e \| n/h,\ ade - bcn/eh^2 = 1 \right\} \tag{2.5.3}$$

where $h = ((n, 24)$ is the largest divisor of 24 such that h^2 divides n (cf. §2.2). The expression (2.5.3) tells us, in particular, that $N(\Gamma_0(n))_\infty = \langle T^{1/h} \rangle$ for $h = ((n, 24)$.

Proposition 2.5.1. *Let $n \in \mathbb{Z}^+$. Then $N(\Gamma_0(n))$ acts transitively on $\hat{\mathbb{Q}}$. We have $N(\Gamma_0(n))_\infty = \Gamma_0(n)_\infty$ if and only if n is not divisible by 4 or 9.*

An important family of groups, each one commensurable with the modular group $G(\mathbb{Z})$, and each one containing and normalizing some $\Gamma_0(n)$, was introduced in [CN79]; these are the groups of *$n\|h$-type*, and we now recall their definition. For $n, h \in \mathbb{Z}^+$ with $h|n$, and for S a subgroup of $\operatorname{Ex}(n/h)$ (cf. §2.2), we define a group $\Gamma_0(n|h) + S$ by setting

$$\Gamma_0(n|h) + S = \left\{ \begin{bmatrix} ae & b/h \\ cn & de \end{bmatrix} \mid a, b, c, d \in \mathbb{Z},\ e \in S,\ ade - bcn/eh = 1 \right\}. \tag{2.5.4}$$

Evidently the group $\Gamma_0(n|h) + S$ contains $\Gamma_0(nh)$. In case $h|24$ it also normalizes $\Gamma_0(nh)$. Assume then that $h|24$. We say that $\Gamma_0(n|h) + S$ is of *Fricke type* if the element $\left[\begin{smallmatrix} 0 & -1 \\ nh & 0 \end{smallmatrix}\right]$ belongs to it.

The group $\Gamma_0(n\|h)+S$ is defined (cf. [CN79]) as the subgroup of $\Gamma_0(n|h)+S$ arising as the kernel of a certain morphism $\Gamma_0(n|h)+S\to\mathbb{Z}/h$ which factors through the canonical map $\Gamma_0(n|h)+S\to(\Gamma_0(n|h)+S)/\Gamma_0(nh)$. In order to describe it let S' denote the image of S in $\mathrm{Ex}(nh)$ under the natural injection $\mathrm{Ex}(n/h)\to\mathrm{Ex}(nh)$ (cf. §2.2). Then as generators for the quotient $(\Gamma_0(n|h)+S)/\Gamma_0(nh)$ we may take the cosets X, Y, and $W_{e'}$ for $e'\in S'$, given by

$$X=\begin{bmatrix}1&1/h\\0&1\end{bmatrix}\Gamma_0(nh),\quad Y=\begin{bmatrix}1&0\\n&1\end{bmatrix}\Gamma_0(nh),\quad W_{e'}=\begin{bmatrix}ae'&b\\cnh&de'\end{bmatrix}\Gamma_0(nh),\tag{2.5.5}$$

where the a, b, c and d in the definition of $W_{e'}$ are arbitrary integers for which $ade'-bcnh/e'=1$, and we may define $\Gamma_0(n\|h)+S$ to be the kernel of the composition

$$\Gamma_0(n|h)+S\to(\Gamma_0(n|h)+S)/\Gamma_0(nh)\xrightarrow{\lambda}\mathbb{Z}/h\tag{2.5.6}$$

where the map λ is determined by the requirements that $\lambda(W_{e'})=0$ for all $e'\in S'$, $\lambda(X)=1$, and $\lambda(Y)$ is 1 or -1 according as $\Gamma_0(n|h)+S$ is of Fricke type or not.

The group $\Gamma_0(n\|h)+S$ is also described in [Fer93], where it is denoted $(1/h)\Gamma_0(n|h)+e_1,e_2,\ldots$ for $S=\{1,e_1,e_2,\ldots\}$, although we should remark that certain variations on λ are considered there (in the case that h is even), so that the class of groups considered in [Fer93] properly contains the groups of $n\|h$-type.

2.6 Scalings

Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p}\in\mathsf{P}_\Gamma$ (cf. (2.5.1)) be a cusp of Γ. An element $p\in\mathsf{p}\subset\hat{\mathbb{Q}}$ will be called a *representative for* p.

Lemma 2.6.1. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $p\in\hat{\mathbb{Q}}$. Then there exists an element $\sigma_p\in G(\mathbb{Q})$ such that*

$$p=\sigma_p\cdot\infty,\quad(\sigma_p^{-1}\Gamma\sigma_p)_\infty=B(\mathbb{Z}).\tag{2.6.1}$$

Proof. In case $p=\infty$ the group Γ_∞ (cf. (2.3.7)) of elements in Γ that fix ∞ is infinite cyclic and generated by some element $\gamma_\infty\in B(\mathbb{Q})$. We claim that in fact γ_∞ lies in $B_u(\mathbb{Q})$, and thus equals T^α (cf. (2.3.4)) for some $\alpha\in\mathbb{Q}^+$. For otherwise $P\det(\gamma_\infty)=e$ for some $e>1$ (cf. (2.3.6)), so that $P\det(\gamma_\infty^n)=e^n$ for $n\in\mathbb{Z}$, since the restriction $P\det:B(\mathbb{Q})\to\mathbb{Z}^+$ is multiplicative. Then each power of γ_∞ lies in a distinct coset of the intersection $\Gamma\cap G(\mathbb{Z})$ in Γ since $P\det$ is invariant under multiplication by elements of $G(\mathbb{Z})$. This contradicts the hypothesis that Γ is commensurable with $G(\mathbb{Z})$, so we conclude that $\Gamma_\infty=\langle T^\alpha\rangle$ for some $\alpha\in\mathbb{Q}^+$. Then we may take $\sigma_\infty = [\alpha]$ (cf. (2.3.3)), for upon calculating $[\mu]T^\alpha[1/\mu] = T^{\mu\alpha}$ we find that

$$([1/\alpha]\Gamma[\alpha])_\infty = [1/\alpha]\Gamma_\infty[\alpha] = [1/\alpha]\langle T^\alpha\rangle[\alpha] = \langle T\rangle, \tag{2.6.2}$$

and the group $\langle T\rangle$ is just $B(\mathbb{Z})$, so the element $\sigma_\infty = [\alpha]$ satisfies the two conditions (2.6.1).

In case $p = a/c$ for coprime integers $a, c \in \mathbb{Z}$ with $c \neq 0$, we may choose $b, d \in \mathbb{Z}$ such that $ad - bc = 1$ and set $\sigma = \left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$. Then $p = \sigma \cdot \infty$ and σ satisfies the first condition in (2.6.1). Now we rerun the argument of the paragraph above with $\sigma^{-1}\Gamma\sigma$ in place of Γ to find that $(\sigma^{-1}\Gamma\sigma)_\infty = \langle T^\alpha\rangle$ for some $\alpha \in \mathbb{Q}^+$, and $\sigma_p = \sigma[\alpha]$ satisfies the two conditions (2.6.1). This completes the proof of the lemma. □

An element $\sigma_p \in G(\mathbb{Q})$ satisfying the two conditions (2.6.1) of Lemma 2.6.1 will be called a *scaling element for* Γ *at the cusp representative* p. It is useful to have a replacement for the notion of scaling element that is independent of a choice of cusp representative.

Lemma 2.6.2. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$ *and let* $\mathsf{p} \in \mathsf{P}_\Gamma$ *be a cusp of* Γ*. Then there exists a coset* $\Sigma_\mathsf{p} \in \Gamma\backslash G(\mathbb{Q})$ *such that*

$$\mathsf{p} = \Sigma_\mathsf{p} \cdot \infty, \quad (\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{p})_\infty = B(\mathbb{Z}). \tag{2.6.3}$$

Proof. Let $p \in \mathsf{p} \subset \hat{\mathbb{Q}}$ be a representative for p and let $\sigma_p \in G(\mathbb{Q})$ satisfy the conditions (2.6.1) of Lemma 2.6.1. Then the coset $\Sigma_\mathsf{p} = \Gamma\sigma_p$ satisfies the conditions (2.6.3). □

A coset $\Sigma_\mathsf{p} \in \Gamma\backslash G(\mathbb{Q})$ satisfying the two conditions (2.6.3) of Lemma 2.6.2 will be called a *scaling coset for* Γ *at the cusp* p. Any element $\sigma \in \Sigma_\mathsf{p}$ is a scaling element for Γ at the representative $\sigma\cdot\infty$ for the cusp p, and if σ_p is a scaling element for Γ at the cusp representative p then the coset $\Gamma\sigma_p$ is a scaling coset for Γ at the cusp $\mathsf{p} = \Gamma \cdot p$ represented by p.

Scaling cosets are determined only up to right multiplication by elements of $B_u(\mathbb{Q})$. Indeed, both the conditions defining the notion of scaling coset are invariant under the replacement of Σ_p by $\Sigma_\mathsf{p}T^\alpha$ for some $\alpha \in \mathbb{Q}$ (cf. (2.3.4)). A set $\{\Sigma_\mathsf{p} \mid \mathsf{p} \in \mathsf{P}_\Gamma\} \subset \Gamma\backslash G(\mathbb{Q})$ such that Σ_p is a scaling coset for Γ at p for each $\mathsf{p} \in \mathsf{P}_\Gamma$ will be called a *system of scaling cosets for* Γ.

The problem of constructing scaling cosets for a group Γ may be viewed in the following way. The group $G(\mathbb{Q})$ acts transitively on $\hat{\mathbb{Q}}$, and the subgroup $B(\mathbb{Q})$ is just the stabilizer of the distinguished point $\infty \in \hat{\mathbb{Q}}$. Thus the map $\Gamma\backslash G(\mathbb{Q}) \to \mathsf{P}_\Gamma$ given by $\Gamma\sigma \mapsto \Gamma\sigma\cdot\infty$ induces an isomorphism $\Gamma\backslash G(\mathbb{Q})/B(\mathbb{Q}) \cong \mathsf{P}_\Gamma$ which we may regard as identifying the sets $\Gamma\backslash G(\mathbb{Q})/B(\mathbb{Q})$ and P_Γ. Now $B(\mathbb{Q})$ is naturally isomorphic to the semidirect product $B_u(\mathbb{Q}) \rtimes B_d(\mathbb{Q})$ (cf. §2.5), so the natural map $\Gamma\backslash G(\mathbb{Q}) \to \Gamma\backslash G(\mathbb{Q})/B(\mathbb{Q})$ factors through $\Gamma\backslash G(\mathbb{Q})/B_u(\mathbb{Q})$, yielding a naturally defined sequence

$$\Gamma\backslash G(\mathbb{Q}) \to \Gamma\backslash G(\mathbb{Q})/B_u(\mathbb{Q}) \to \Gamma\backslash G(\mathbb{Q})/B(\mathbb{Q}) \cong \mathsf{P}_\Gamma \tag{2.6.4}$$

where the fibres of the second map are torsors for the diagonal group $B_d(\mathbb{Q}) \simeq \mathbb{Q}^+$. Given a cusp $\mathsf{p} \in \mathsf{P}_\Gamma$, any preimage of p in $\Gamma\backslash G(\mathbb{Q})$ under the composition (2.6.4) is a coset of Γ satisfying the first condition defining a scaling coset for Γ at p. In order to satisfy also the second condition we should multiply this coset by $[\mu]$ (cf. (2.3.3)) for some (uniquely defined) $\mu \in \mathbb{Q}^+$. Thus the two conditions defining scaling cosets define a section of the $B_d(\mathbb{Q})$-bundle $\Gamma\backslash G(\mathbb{Q})/B_u(\mathbb{Q}) \to \mathsf{P}_\Gamma$. We denote this map $\mathsf{p} \mapsto \mathfrak{S}_\mathsf{p}$. We may naturally identify $\mathfrak{S}_\mathsf{p}$ with the set of scaling cosets for Γ at p, for these are precisely the preimages of $\mathfrak{S}_\mathsf{p}$ in $\Gamma\backslash G(\mathbb{Q})$ under the first map of (2.6.4).

$$\begin{aligned} \mathsf{P}_\Gamma &\to \Gamma\backslash G(\mathbb{Q})/B_u(\mathbb{Q}) \\ \mathsf{p} &\mapsto \mathfrak{S}_\mathsf{p} = \{\Sigma_\mathsf{p} T^\alpha \mid \alpha \in \mathbb{Q}\} \end{aligned} \tag{2.6.5}$$

One says that Γ has *width one at infinity* in the case that $\Gamma_\infty = B(\mathbb{Z})$. Observe that Γ has width one at infinity if and only if Γ is a scaling coset for itself at the infinite cusp $\Gamma \cdot \infty$; that is, if and only if $\Gamma \in \mathfrak{S}_{\Gamma\cdot\infty}$. If Γ does not have width one at infinity then there is a unique $\mu \in \mathbb{Q}^+$ with the property that $\Gamma[\mu]$ is a scaling coset for Γ at the infinite cusp $\Gamma \cdot \infty$, and then the group $\Gamma^{[\mu]} = [1/\mu]\Gamma[\mu]$ is a group with width one at infinity.

When engaged in the task of computing Fourier coefficients of modular forms for a group Γ say, one frequently has use for double coset spaces of the form $\Gamma_p\backslash\Gamma/\Gamma_q$, for some $p, q \in \hat{\mathbb{Q}}$, where Γ_p denotes the stabilizer in Γ of p. If σ_p and σ_q are scaling elements for Γ at p and q, respectively, then we have $\sigma_p^{-1}\Gamma_p\sigma_p = B(\mathbb{Z})$, and similarly with q in place of p, so the set of *translates*

$$\sigma_p^{-1}(\Gamma_p\backslash\Gamma/\Gamma_q)\sigma_q = \{\sigma_p^{-1}\Gamma_p\gamma\Gamma_q\sigma_q \mid \gamma \in \Gamma\} \tag{2.6.6}$$

is in fact a set of double cosets of $B(\mathbb{Z})$. In the notation of §2.4 we have

$$\sigma_p^{-1}(\Gamma_p\backslash\Gamma/\Gamma_q)\sigma_q = [\![\sigma_p^{-1}\Gamma\sigma_q]\!] = \left\{ [\![\sigma_p^{-1}\gamma\sigma_q]\!] \mid \gamma \in \Gamma \right\}. \tag{2.6.7}$$

Set $\mathsf{p} = \Gamma \cdot p$ and $\mathsf{q} = \Gamma \cdot q$, and set $\Sigma_\mathsf{p} = \Gamma\sigma_p$ and $\Sigma_\mathsf{q} = \Gamma\sigma_q$, so that Σ_p and Σ_q are scaling cosets for Γ at p and q, respectively. Then we have $\sigma_p^{-1}\Gamma\sigma_q = \Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}$, so that these translates depend only on cusps, and not on cusp representatives. We see from this discussion that for any pair of cusps $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$, with scaling cosets Σ_p and Σ_q, respectively, the set $\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}$ is a union of double cosets of $B(\mathbb{Z})$. The assignment $(\mathsf{p}, \mathsf{q}) \mapsto \Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}$ is sensitive to the choice of scaling cosets Σ_p and Σ_q, to the extent that a different choice will replace $\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}$ with a set of the form $T^\alpha\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}T^\beta$ for some $\alpha, \beta \in \mathbb{Q}$.

In general there may be no canonical choice of scaling coset for a particular group at a particular cusp, but there are situations in which some choices might be preferred over others. For example, it is natural to take $\Sigma_{\Gamma\cdot\infty} = \Gamma$ in case Γ has width one at infinity, for we then have $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} = \Sigma_{\mathsf{p}}^{-1}$ when $\mathsf{q} = \Gamma\cdot\infty$, and $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} = \Sigma_{\mathsf{q}}$ when $\mathsf{p} = \Gamma\cdot\infty$, and $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} = \Gamma$ when $\mathsf{p} = \mathsf{q} = \Gamma\cdot\infty$. We shall always take the scaling coset $\Sigma_{\Gamma\cdot\infty}$, for Γ at the infinite cusp, to be of the form $\Gamma[\mu]$ for $\mu \in \mathbb{Q}^+$. This value μ is uniquely determined.

Observe that if Σ_{p} and Σ_{q} are scaling cosets for Γ at p and q, respectively, then the intersection $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} \cap B(\mathbb{Q}) = (\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}})_\infty$ can be non-empty only in the case that $\mathsf{p} = \mathsf{q}$. For p and q cusps for Γ we define $\delta_{\Gamma|\mathsf{p},\mathsf{q}}$ to be 1 or 0 according as $\mathsf{p} = \mathsf{q}$ or not.

Given a system $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ of scaling cosets for Γ, we write Γ^{p} as a shorthand for the group obtained as the conjugate of Γ by Σ_{p}.

$$\Gamma^{\mathsf{p}} = \Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}} \tag{2.6.8}$$

The notation (2.6.8) suppresses the dependence on the choice of scaling coset: a different choice will replace Γ^{p} with a group of the form $T^{-\alpha}\Gamma^{\mathsf{p}}T^{\alpha}$ for some $\alpha \in \mathbb{Q}$.

2.7 Integrals

Write $\mathcal{O}(\mathbb{H})$ for the ring of holomorphic functions on the upper half plane $\mathbb{H}$.

For $\kappa \in \mathbb{Z}$, we define the *weight 2κ (right) action of $G(\mathbb{Q})$ on $\mathcal{O}(\mathbb{H})$*, to be denoted $(f,\chi) \mapsto f|^{\kappa}\chi$, by setting

$$\left(f|^{\kappa}\chi\right)(z) = f(\chi\cdot z)\,\mathrm{jac}(\chi,z)^{\kappa} \tag{2.7.1}$$

for $f \in \mathcal{O}(\mathbb{H})$ and $\chi \in G(\mathbb{Q})$. For Γ a group commensurable with $G(\mathbb{Z})$ (and hence a subgroup of $G(\mathbb{Q})$), we call $f \in \mathcal{O}(\mathbb{H})$ an *unrestricted modular form of weight 2κ for* Γ in case it is a fixed point for the weight 2κ action of Γ. Suppose f is an unrestricted modular form of weight 2κ for Γ. Then for $X \in \Gamma\backslash G(\mathbb{Q})$ a right coset of Γ in $G(\mathbb{Q})$ we may define a function $(f\|^{\kappa}_{\Gamma}X)(z)$ by setting

$$f\|^{\kappa}_{\Gamma}X = f|^{\kappa}\chi \tag{2.7.2}$$

where χ is any representative for the coset $X \in \Gamma\backslash G(\mathbb{Q})$. Let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ and let $\Sigma_{\mathsf{p}} \in \Gamma\backslash G(\mathbb{Q})$ a scaling coset for Γ at p. Then for f an unrestricted modular form of weight 2κ for Γ we define $f_{|\mathsf{p}} \in \mathcal{O}(\mathbb{H})$ by setting $f_{|\mathsf{p}} = f\|^{\kappa}_{\Gamma}\Sigma_{\mathsf{p}}$. Then $f_{|\mathsf{p}}(z+1) = f_{|\mathsf{p}}(z)$ for all $z \in \mathbb{H}$, by the defining properties of Σ_{p} (cf. §2.6), so we have

$$f_{|\mathsf{p}}(z)=\sum_{n\in\mathbb{Z}}c_{|\mathsf{p}}(n)\,\mathrm{e}(nz) \tag{2.7.3}$$

for some $c_{|\mathsf{p}}(n)\in\mathbb{Z}$. We call the right hand side of (2.7.3) the *Fourier expansion of* f *at* p *with respect to* Σ_{p}, and we say that f is *meromorphic at* p if the right hand side of (2.7.3) is a meromorphic function of $q=\mathrm{e}(z)$ in a neighborhood of $q=0$. A different choice of scaling coset will replace $c_{|\mathsf{p}}(n)$ with $\mathrm{e}(n\alpha)c_{|\mathsf{p}}(n)$ for some $\alpha\in\mathbb{Q}$, so the notion of being meromorphic at p is independent of the choice of scaling coset at p.

We define $M_\kappa(\Gamma)$ to be the vector space consisting of unrestricted modular forms of weight 2κ for Γ that are meromorphic at the cusps of Γ. In a slight departure from standard convention we call $M_\kappa(\Gamma)$ the space of *modular forms of weight* 2κ *for* Γ. We define $S_\kappa(\Gamma)$ to be the vector space consisting of modular forms of weight 2κ for Γ that vanish at the cusps of Γ. We call $S_\kappa(\Gamma)$ the space of *cusp forms of weight* 2κ *for* Γ. The vector space $S_\kappa(\Gamma)$ is the zero vector space when $\kappa\leq 0$.

Let $\kappa\in\mathbb{Z}$ such that $\kappa\leq 0$, and let $w\in\mathbb{H}\cup\hat{\mathbb{Q}}$. Given a holomorphic function $g(z)$ on $\mathbb{H}$ with sufficiently rapid decay as the imaginary part of z tends to ∞ we define a function $I^\kappa_w g$ on $\mathbb{C}$ by setting $I^\kappa_\infty g$ to be the zero function and by setting

$$(I^\kappa_w g)(z)=2\pi\mathbf{i}\int_w^\infty g(\xi)(2\pi\mathbf{i}(\xi-z))^{(-2\kappa)}\mathrm{d}\xi \tag{2.7.4}$$

for $w\neq\infty$, where the integral is taken over the vertical line $\{w+\mathbf{i}t\mid t\in\mathbb{R}^+\}$. In our applications g will either be a cusp form (for some $\Gamma<PSL_2(\mathbb{R})$ commensurable with $PSL_2(\mathbb{Z})$) or will admit a finite power series expansion of the form $g(z)=\sum_{n=1}^N c(n)\,\mathrm{e}(nz)$. In these cases the convergence of the integral defining $I^\kappa_w g$ is clear.

We define a closely related operator $g\mapsto J^\kappa_w g$ by setting

$$(J^\kappa_w g)(z)=\overline{(I^\kappa_w g)(\bar{z})}. \tag{2.7.5}$$

Observe that when $\kappa\leq 0$, the functions $(I^\kappa_w g)(z)$ and $(J^\kappa_w g)(z)$ are polynomials of degree at most -2κ in z . For $\chi\in G(\mathbb{Q})$ we have

$$(I^\kappa_w g)|^\kappa\chi=I^\kappa_{w\cdot\chi}\left(g|^{1-\kappa}\chi\right)-I^\kappa_{\infty\cdot\chi}\left(g|^{1-\kappa}\chi\right) \tag{2.7.6}$$

where $w\cdot\chi=\chi^{-1}\cdot w$ denotes the natural right action of $G(\mathbb{Q})$ on $\mathbb{H}\cup\hat{\mathbb{Q}}$. In particular, if $g\in M_{1-\kappa}(\Gamma)$ for some group Γ then we have $(I^\kappa_w g)|^\kappa\gamma=I^\kappa_{w\cdot\gamma}g-I^\kappa_{\infty\cdot\gamma}g$ for $\gamma\in\Gamma$.

Lemma 2.7.1. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$*, let* $\kappa\in\mathbb{Z}$ *such that* $\kappa\leq 0$*, and let* $g\in S_{1-\kappa}(\Gamma)$*. Then we have* $I^\kappa_p g=0$ *for all* $p\in\hat{\mathbb{Q}}$ *if and only if* $g=0$*.*

Proof. Certainly $I_p^\kappa g = 0$ for all $p \in \hat{\mathbb{Q}}$ if $g = 0$, so let $g \in S_{1-\kappa}(\Gamma)$ such that $I_p^\kappa g = 0$ for all $p \in \hat{\mathbb{Q}}$. Following the proof of Lemma 3.2 in [Nie74] we define a function $f(z)$ by setting

$$f(z) = (I_z^\kappa g)(z) = 2\pi\mathbf{i}\int_z^\infty g(\xi)(2\pi\mathbf{i}(\xi - z))^{(-2\kappa)}\mathrm{d}\xi. \tag{2.7.7}$$

The identity (2.7.6) implies $f|^\kappa\gamma = f - I^\kappa_{\infty\cdot\gamma}g$ for $\gamma \in \Gamma$, so that f is an unrestricted modular form of weight 2κ for Γ. We should consider the behavior of f at the cusps of Γ. Let $\mathsf{p} \in \mathsf{P}_\Gamma$, and let Σ_p be a scaling coset for Γ at p. Then we have

$$g_{|\mathsf{p}}(\xi) = \sum_{n>0} b_{|\mathsf{p}}(n)\,\mathrm{e}(n\xi) \tag{2.7.8}$$

for some $b_{|\mathsf{p}}(n) \in \mathbb{C}$, where $g_{|\mathsf{p}} = g\|_\Gamma^{1-\kappa}\Sigma_\mathsf{p}$ (cf. (2.7.2)). In order to analyze $f_{|\mathsf{p}} = f\|_\Gamma^\kappa\Sigma_\mathsf{p}$ we choose $\sigma \in \Sigma_\mathsf{p}$ and compute

$$f|^\kappa\sigma = I_z^\kappa(g_{|\mathsf{p}}) - I^\kappa_{\infty\cdot\sigma}(g_{|\mathsf{p}}) \tag{2.7.9}$$

by (2.7.6). Now the term $I^\kappa_{\infty\cdot\sigma}(g_{|\mathsf{p}})$ vanishes, since we have

$$\begin{aligned}(I^\kappa_{\infty\cdot\sigma}(g_{|\mathsf{p}}))(z) &= 2\pi\mathbf{i}^{1-2\kappa}\int_{\sigma^{-1}\cdot\infty}^\infty g(\sigma\cdot\xi)\,\mathrm{jac}(\sigma,\xi)^{1-\kappa}(\xi - z)^{(-2\kappa)}\mathrm{d}\xi \\ &= 2\pi\mathbf{i}^{1-2\kappa}\int_{\sigma^{-1}\cdot\infty}^\infty g(\sigma\cdot\xi)(\sigma\cdot\xi - \sigma\cdot z)^{(-2\kappa)}\,\mathrm{jac}(\sigma,z)^\kappa\mathrm{d}(\sigma\cdot\xi) \\ &= -(I^\kappa_{\sigma\cdot\infty}g)\,\mathrm{jac}(\sigma,z)^\kappa,\end{aligned} \tag{2.7.10}$$

which vanishes by our hypothesis on g. So we have the Fourier expansion

$$f_{|\mathsf{p}}(z) = \sum_{n>0} c_{|\mathsf{p}}(n)\,\mathrm{e}(nz) \tag{2.7.11}$$

for f at p, where $c_{|\mathsf{p}}(n)$ is determined by $b_{|\mathsf{p}}(n)$ according to the formula

$$c_{|\mathsf{p}}(n) = b_{|\mathsf{p}}(n)2\pi\mathbf{i}(I_0^\kappa g)(0) = -n^{2\kappa-1}b_\mathsf{p}(n). \tag{2.7.12}$$

We conclude that f is a cusp form of weight κ. Since $\kappa \leq 0$ we have $S_\kappa(\Gamma) = 0$, and so $c_{|\mathsf{p}}(n) = 0$ for all $n \in \mathbb{Z}$ and all $\mathsf{p} \in \mathsf{P}_\Gamma$, and so $b_{|\mathsf{p}}(n) = 0$ for all $n \in \mathbb{Z}$ and all $\mathsf{p} \in \mathsf{P}_\Gamma$. That is to say, g vanishes identically, which is what we required to show. □

Let $\kappa \in \mathbb{Z}$ such that $\kappa \leq 0$. Following Niebur (cf. [Nie74]) we say that a holomorphic function $f \in \mathcal{O}(\mathbb{H})$ is an *unrestricted automorphic integral of weight* 2κ *for* Γ in case there exists a cusp form $g \in S_{1-\kappa}(\Gamma)$ such that

$$f|^{\kappa}\gamma = f - J^{\kappa}_{\infty\cdot\gamma}g \tag{2.7.13}$$

for each $\gamma \in \Gamma$. According to Lemma 2.7.1 the cusp form $g \in S_{1-\kappa}(\Gamma)$ satisfying (2.7.13) is uniquely determined. We call it the *cusp form associated to the unrestricted automorphic integral* f. The operator $f \mapsto f\|^{\kappa}_{\Gamma}X$, for X a right coset of Γ, may be extended to unrestricted automorphic integrals as follows. Suppose f is an unrestricted automorphic integral of weight 2κ for Γ with associated cusp form g. Then for $X \in \Gamma\backslash G(\mathbb{Q})$ we may define $f\|^{\kappa}_{\Gamma}X \in \mathcal{O}(\mathbb{H})$ by setting

$$f\|^{\kappa}_{\Gamma}X = (f - J^{\kappa}_{\chi\cdot\infty}g)|^{\kappa}\chi \tag{2.7.14}$$

where χ is any representative for the coset $X \in \Gamma\backslash G(\mathbb{Q})$. The transformation properties (2.7.6) and (2.7.13) confirm that the function $f\|^{\kappa}_{\Gamma}X$ is independent of the choice of coset representative χ. Let Σ_{p} be a scaling coset for Γ at a cusp $\mathsf{p} \in \mathsf{P}_{\Gamma}$, and define $f_{|\mathsf{p}}$ by setting

$$f_{|\mathsf{p}} = f\|^{\kappa}_{\Gamma}\Sigma_{\mathsf{p}}. \tag{2.7.15}$$

By the defining properties of scaling cosets we find that $f_{|\mathsf{p}}(z+1) = f_{|\mathsf{p}}(z)$ for all $z \in \mathbb{H}$, and so we have

$$f_{|\mathsf{p}}(z) = \sum_{n\in\mathbb{Z}} c_{|\mathsf{p}}(n)\,\mathrm{e}(nz) \tag{2.7.16}$$

for some $c_{|\mathsf{p}}(n) \in \mathbb{C}$. We call (2.7.16) the *Fourier expansion of* f *at* p *with respect to* Σ_{p}, and we say that f is *meromorphic at* p if the right hand side of (2.7.16) is a meromorphic function of $q = \mathrm{e}(z)$ in a neighborhood of $q = 0$.

We define $I_{\kappa}(\Gamma)$ to be the vector space consisting of unrestricted automorphic integrals of weight 2κ for Γ that are meromorphic at every cusp of Γ. We call $I_{\kappa}(\Gamma)$ the space of *automorphic integrals of weight* 2κ *for* Γ.

The space $M_{\kappa}(\Gamma)$ of modular forms of weight 2κ for Γ is a subspace of $I_{\kappa}(\Gamma)$ by definition. Lemma 2.7.1 may be regarded as stating that $M_{\kappa}(\Gamma)$ is the kernel of the map $I_{\kappa}(\Gamma) \to S_{1-\kappa}(\Gamma)$ which sends an automorphic integral f to its associated cusp form g (cf. (2.7.13)). We will see in §4.5 that the map $I_{\kappa}(\Gamma) \to S_{1-\kappa}(\Gamma)$ is surjective, so that we have an exact sequence of vector spaces

$$0 \to M_{\kappa}(\Gamma) \to I_{\kappa}(\Gamma) \to S_{1-\kappa}(\Gamma) \to 0. \tag{2.7.17}$$

The sequence (2.7.17) is trivially exact in case $\kappa > 0$, for then $S_{1-\kappa}(\Gamma) = 0$, so that an automorphic integral of weight 2κ is automatically a modular form. Indeed, and more generally, if $\kappa \in \mathbb{Z}$ is chosen so that $S_{1-\kappa}(\Gamma) = 0$, then the spaces $M_\kappa(\Gamma)$ and $I_\kappa(\Gamma)$ coincide by the definition (cf. (2.7.13)) of an automorphic integral.

3 Rademacher sums

In this section we associate Rademacher sums, and conjugate Rademacher sums (cf. §1.3), of arbitrary even integer weight to triples $(\Gamma, \mathsf{p}, \mathsf{q})$ where Γ is a group commensurable with the modular group and p and q are cusps for Γ. We derive explicit expressions for the Fourier expansions of these functions, and study how they transform under the action of Γ.

3.1 Construction

Given $\kappa, m \in \mathbb{Z}$ and $\llbracket \chi \in \llbracket G(\mathbb{Q})$, define a function $z \mapsto P^{\kappa(m)}_{\llbracket \chi}(z)$ on $\mathbb{H}$ by setting

$$P^{\kappa(m)}_{\llbracket \chi}(z) = \mathrm{e}(m \llbracket \chi \cdot z)\, \mathrm{jac}(\llbracket \chi\, , z)^{\kappa}. \tag{3.1.1}$$

Given $U \subset \llbracket G(\mathbb{Q})$, define the *holomorphic Poincaré series of weight 2κ and order m associated to U*, to be denoted $P^{\kappa(m)}_{U}(z)$, by setting

$$P^{\kappa(m)}_{U}(z) = \lim_{K\to\infty} \sum_{\llbracket \chi \in U_{\leq K}} P^{\kappa(m)}_{\llbracket \chi}(z) \tag{3.1.2}$$

where $U_{\leq K}$ is as in (2.4.6). Of course, the limit defining $P^{\kappa(m)}_{U}(z)$ may or may not converge depending on the choice of κ, m, and U. If $\kappa > 1$ and $m \geq 0$ then for $U = \llbracket \Gamma$ say, for Γ a group commensurable with $G(\mathbb{Z})$, the limiting sum in (3.1.2) converges absolutely and uniformly on compact subsets of $\mathbb{H}$ (cf. Lemma 3.4.2) and the symbols $\lim_{K\to\infty}$ and ${}_{\leq K}$ are unnecessary. If $\kappa \leq 0$ then even with the limit the expression on the right hand side of (3.1.2) fails to converge, and the Poincaré series $P^{\kappa(m)}_{U}(z)$ is not defined.

As was originally demonstrated by Rademacher in [Rad39], the non-convergence of the Poincaré series $P^{\kappa(m)}_{U}(z)$ when $\kappa = 0$ can be circumvented by replacing $P^{0(m)}_{\llbracket \chi}(z)$ with $P^{0(m)}_{\llbracket \chi}(z) - P^{0(m)}_{0,\llbracket \chi}$ in the right-hand side of (3.1.2) where

$$P^{0(m)}_{\llbracket \chi}(z) - P^{0(m)}_{0,\llbracket \chi} = \mathrm{e}(m \llbracket \chi \cdot z) - \mathrm{e}(m \llbracket \chi \cdot \infty) \tag{3.1.3}$$

in case $\llbracket \chi \in \llbracket G(\mathbb{Q})^{\times}$, and $P^{0(m)}_{0,\llbracket \chi} = 0$ otherwise. Rademacher showed for $m = -1$ (cf. loc. cit.) that the resulting expression is a (conditionally) convergent series which recovers a function invariant for the modular group $G(\mathbb{Z})$ in the case that $U = \llbracket G(\mathbb{Z})$. Generalizations of

Rademacher's construction were given by Knopp (cf. [Kno62a]) and Niebur (cf. [Nie74]) so as to obtain conditionally convergent Poincaré series for arbitrary real non-positive weights, for various subgroups of $G(\mathbb{R}) = PSL_2(\mathbb{R})$.

With the constructions of Rademacher, Knopp and Niebur in mind, we introduce the *Rademacher component function of weight* 2κ *and order* m *associated to* $\llbracket\chi$, denoted $z \mapsto R^{\kappa(m)}_{\llbracket\chi}(z)$ and defined for $\kappa, m \in \mathbb{Z}$ and $\llbracket\chi \in \llbracket G(\mathbb{Q})$, by setting

$$R^{\kappa(m)}_{\llbracket\chi}(z) = \mathrm{e}(m\llbracket\chi\cdot z)\,\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z)\,\mathrm{jac}(\llbracket\chi\,,z)^{\kappa}, \tag{3.1.4}$$

where $\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z)$ is the *Rademacher regularization factor of weight* 2κ, given by

$$\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z) = \Phi(1-2\kappa, 2-2\kappa, m\llbracket\chi\cdot\infty - m\llbracket\chi\cdot z)(2\pi\mathbf{i}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty))^{1-2\kappa} \tag{3.1.5}$$

in case $\chi \in G(\mathbb{Q})^{\times}$, and $\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z) = 1$ otherwise (cf. (2.1.3)). The function $R^{\kappa(m)}_{\llbracket\chi}(z)$ is entire in case $\chi \in B(\mathbb{Q})$, and is otherwise holomorphic away from $z = \chi^{-1}\cdot\infty$. For $U \subset \llbracket G(\mathbb{Q})$ we define the *classical Rademacher sum of weight* 2κ *and order* m *associated to* U, to be denoted $R^{\kappa(m)}_{U}(z)$, by setting

$$R^{\kappa(m)}_{U}(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} R^{\kappa(m)}_{\llbracket\chi}(z). \tag{3.1.6}$$

Again, the expression defining $R^{\kappa(m)}_{U}(z)$ will not converge for all choices of κ, m and U. Employing the Kummer transformation (2.1.4) we may rewrite the Rademacher component function $R^{\kappa(m)}_{\llbracket\chi}(z)$ as

$$R^{\kappa(m)}_{\llbracket\chi}(z) = \mathrm{e}(m\llbracket\chi\cdot\infty)\,\mathrm{e}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty, 1-2\kappa)\,\mathrm{jac}(\llbracket\chi\,,z)^{\kappa} \tag{3.1.7}$$

in case $\llbracket\chi \in \llbracket G(\mathbb{Q})^{\times}$, where $\mathrm{e}(z,s)$ is the generalized exponential function of (2.1.6). Since we restrict attention to the case that κ is an integer (cf. [Nie74] for non-integral weights), the generalized exponential in (3.1.7) may in turn be written in terms of the partial exponential function $\mathrm{e}(z)_{<K}$ (cf. §2.1). We thus obtain the identity

$$\mathrm{e}(m\llbracket\chi\cdot z)\,\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z) = \mathrm{e}(m\llbracket\chi\cdot z) - \mathrm{e}(m\llbracket\chi\cdot\infty)\,\mathrm{e}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty)_{<1-2\kappa} \tag{3.1.8}$$

when $\chi \in G(\mathbb{Q})^{\times}$. In particular, we have $\mathrm{r}^{\kappa}(m,\llbracket\chi\,,z) = 1$ when κ is positive, so that the Rademacher sum $R^{\kappa(m)}_{U}(z)$ is exactly (albeit formally) the Poincaré series $P^{\kappa(m)}_{U}(z)$ when $\kappa > 0$.

The case that $\kappa = 0$ is special, for the corresponding Poincaré series, if it were to converge, would define a Γ-invariant function on $\mathbb{H}$ for any group Γ satisfying $U\Gamma = U$. With $\kappa = 0$ we have $\mathrm{r}^0(m, \llbracket\chi\,, z) = 1 - \mathrm{e}(m \llbracket\chi \cdot \infty - m \llbracket\chi \cdot z)$ when $\chi \in G(\mathbb{Q})^\times$, and hence

$$R^{0(m)}_{\llbracket\chi}(z) = P^{0(m)}_{\llbracket\chi}(z) - P^{0(m)}_{0,\llbracket\chi} \tag{3.1.9}$$

for all $\llbracket\chi \in \llbracket G(\mathbb{Q})^\times$. In other words, the Rademacher sum $R^{0(m)}_U(z)$ is given by

$$\begin{aligned} R^{0(m)}_U(z) &= \lim_{K\to\infty} \sum_{\llbracket\chi \in U^\times_{\leq K}} P^{0(m)}_{\llbracket\chi}(z) - P^{0(m)}_{0,\llbracket\chi} \\ &= \sum_{\llbracket\chi \in U_\infty} \mathrm{e}(m \llbracket\chi \cdot z) + \lim_{K\to\infty} \sum_{\llbracket\chi \in U^\times_{\leq K}} \mathrm{e}(m \llbracket\chi \cdot z) - \mathrm{e}(m \llbracket\chi \cdot \infty), \end{aligned} \tag{3.1.10}$$

with the latter expression holding at least when there are only finitely many cosets of $B(\mathbb{Z})$ in U_∞. This expression (3.1.10), with $m = -1$ and $U = \llbracket G(\mathbb{Z})$, is the series originally considered by Rademacher in [Rad39].

It is interesting to consider the function obtained by substituting $\bar{z}$ for z in the right hand side of (3.1.6). We define the *conjugate Rademacher sum of weight 2κ and order m associated to U*, to be denoted $\bar{R}^{\kappa(m)}_U(z)$, by setting

$$\bar{R}^{\kappa(m)}_U(z) = \lim_{K\to\infty} \sum_{\llbracket\chi \in U_{\leq K}} \bar{R}^{\kappa(m)}_{\llbracket\chi}(z), \tag{3.1.11}$$

where $\bar{R}^{\kappa(m)}_{\llbracket\chi}(z) = R^{\kappa(m)}_{\llbracket\chi}(\bar{z})$ by definition. Evidently, the conjugate Rademacher sum $\bar{R}^{\kappa(m)}_U(z)$ is an anti-holomorphic function on $\mathbb{H}$ whenever U, κ and m are such that the limit in (3.1.11) converges locally uniformly in z. At first glance it appears that we should recover the classical Rademacher sum $R^{\kappa(m)}_U(z)$ from the conjugate Rademacher sum according to the identity $R^{\kappa(m)}_U(z) = \bar{R}^{\kappa(m)}_U(\bar{z})$, but as we shall see in §3.4 the relationship between the holomorphic functions $R^{\kappa(m)}_U(z)$ and $\bar{R}^{\kappa(m)}_U(\bar{z})$ is generally more interesting that this.

We typically take U to be of the form $U = \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ where $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ is a system of scaling cosets (cf. §2.6) for some group Γ commensurable with the modular group, and $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ are cusps of Γ. In this case we write $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for $R^{\kappa(m)}_U(z)$, and similarly for the holomorphic Poincaré series, suppressing the choice of scaling cosets from notation. A change in the choice of Σ_{p} and Σ_{q} replaces $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ with a function of the form $\mathrm{e}(\alpha)R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z+\beta)$ for some $\alpha, \beta \in \mathbb{Q}$, and similarly for the holomorphic Poincaré series $P^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$.

In the case that p or q is the *infinite cusp* $\Gamma \cdot \infty$ we omit it from notation, writing $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ for $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\Gamma\cdot\infty}(z)$, and $R^{\kappa(m)}_{\Gamma|\mathsf{q}}(z)$ for $R^{\kappa(m)}_{\Gamma,\Gamma\cdot\infty|\mathsf{q}}(z)$, and similarly for the holomorphic Poincaré series. The functions $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ are, in a sense, the most important, for we shall see in §3.4 that $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is, up to addition by a certain constant function, an automorphic integral of weight 2κ for Γ with a single pole at the cusp p in case Γ has width one at infinity (cf. §2.6) and $\kappa \leq 0$ and $m < 0$. We shall see also in §3.4 (cf. Theorems 3.4.3 and 3.4.4) that the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$, once corrected by adding a certain constant function in case $\kappa \leq 0$, is the expansion (of the correction by addition of a certain constant) of $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ at the cusp q in the sense of §2.7.

To further emphasize the importance of the functions $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ we observe that every Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is of the form $R^{\kappa(m)}_{\Gamma',\mathsf{p}'}(z)$ for some group Γ' with width one at infinity, and some cusp p' of Γ'. For if Σ_{p} and Σ_{q} are the chosen scaling sets for Γ at p and q, respectively, then we have $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = R^{\kappa(m)}_{U}(z)$ for $U = \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$. Recall (cf. (2.6.8)) that Γ^{q} is a shorthand for the group $\Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{q}}$, and this group Γ^{q} has width one at infinity by the defining properties of scaling cosets. If we define $\mathsf{p}^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1} \cdot \mathsf{p} \subset \hat{\mathbb{Q}}$ then p^{q} is a cusp of Γ^{q}, and $\Sigma_{\mathsf{p}^{\mathsf{q}}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}$ is a scaling coset for Γ^{q} at p^{q}. We now have $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} = \Sigma_{\mathsf{p}^{\mathsf{q}}}^{-1}$, so that $U = \llbracket\Sigma_{\mathsf{p}^{\mathsf{q}}}^{-1}$. Since Γ^{q} has width one at infinity we may take it to be a scaling coset for itself at the infinite cusp, and we thus have

$$R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = R^{\kappa(m)}_{\Gamma^{\mathsf{q}},\mathsf{p}^{\mathsf{q}}}(z) \tag{3.1.12}$$

subject to a consistent choice of scaling cosets for Γ and Γ^{q}. More explicitly, the equality in (3.1.12) holds in case $\Gamma^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{q}}$ and $\mathsf{p}^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1} \cdot \mathsf{p}$ and $\Sigma_{\mathsf{p}^{\mathsf{q}}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}$.

Our primary interest in this article is in the distinguished case that $\kappa = 0$. In order to simplify notation, and maintain consistency with the notation of §1, we write $R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ as a shorthand for $R^{0(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$.

We conclude this section with a result which expresses the Rademacher component function $R^{\kappa(m)}_{\llbracket\chi}(z)$ in terms of the functions $P^{\kappa(m)}_{\llbracket\chi}(z)$ of (3.1.1) and the integral operator J^{κ}_{w} of §2.7.

Lemma 3.1.1. *Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$, and let $\llbracket\chi \in \llbracket G(\mathbb{Q})$. Then we have*

$$R^{\kappa(m)}_{\llbracket\chi}(z) = P^{\kappa(m)}_{\llbracket\chi}(z) - m^{1-2\kappa}\left(J^{\kappa}_{\infty\cdot\llbracket\chi}P^{1-\kappa(-m)}_{\llbracket\chi}\right)(z). \tag{3.1.13}$$

Proof. In case $\llbracket\chi \in \llbracket G(\mathbb{Q})_{\infty}$ the second term in the right hand side of (3.1.13) vanishes (cf. (3.1.15)), and the identity (3.1.13) then holds by the definition of $R^{\kappa(m)}_{\llbracket\chi}(z)$, so we assume henceforth that $\llbracket\chi \in \llbracket G(\mathbb{Q})^{\times}$. By (3.1.8) we may write the Rademacher component function $R^{\kappa(m)}_{\llbracket\chi}(z)$ as

$$\mathrm{e}(m\llbracket\chi\cdot z)\,\mathrm{jac}(\llbracket\chi, z)^{\kappa} - \mathrm{e}(m\llbracket\chi\cdot\infty)\,\mathrm{e}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty)_{<1-2\kappa}\,\mathrm{jac}(\llbracket\chi, z)^{\kappa}. \tag{3.1.14}$$

The first term in (3.1.14) is just $P^{\kappa(m)}_{\llbracket\chi}(z)$, and a contour integral calculation confirms that the second term in (3.1.14) is $m^{1-2\kappa}$ times the image of $P^{1-\kappa(-m)}_{\llbracket\chi}(z)$ under $J^{\kappa}_{\infty\cdot\llbracket\chi}$. The details of this contour integral calculation are as follows. We have

$$\overline{\left(J^{\kappa}_{\infty\cdot\llbracket\chi}P^{1-\kappa(-m)}_{\llbracket\chi}\right)}(z) = (2\pi\mathbf{i})^{1-2\kappa}\int_{\chi^{-1}\rrbracket\cdot\infty}^{\infty}\mathrm{e}(-m\llbracket\chi\cdot\xi)\,\mathrm{jac}(\llbracket\chi, \xi)^{1-\kappa}(\xi - \bar{z})^{(-2\kappa)}\mathrm{d}\xi \tag{3.1.15}$$

by the definition of J_w^κ (cf. §2.7). Choosing a representative χ for the coset $\llbracket\chi$ we compute

$$\begin{aligned}
&\int_{\chi^{-1}\rrbracket\cdot\infty}^{\infty} \mathrm{e}(-m\llbracket\chi\cdot\xi)\,\mathrm{jac}(\llbracket\chi\,,\xi)^{1-\kappa}(\xi-\bar{z})^{(-2\kappa)}\mathrm{d}\xi \\
&= \mathrm{e}(-m\chi\cdot\infty)\int_{\infty}^{\chi\cdot\infty} \mathrm{e}(m\chi\cdot\infty-m\chi\cdot\xi)(\chi\cdot\xi-\chi\cdot\bar{z})^{(-2\kappa)}\mathrm{d}(\chi\cdot\xi)\,\mathrm{jac}(\chi,\bar{z})^{\kappa} \\
&= -\,\mathrm{e}(-m\chi\cdot\infty)\int_{\chi\cdot\infty}^{\infty} \mathrm{e}(m\chi\cdot\infty-m\xi)(\xi-\chi\cdot\bar{z})^{(-2\kappa)}\mathrm{d}\xi\,\mathrm{jac}(\chi,\bar{z})^{\kappa} \\
&= -\,\mathrm{e}(-m\chi\cdot\infty)\int_{0}^{\infty} \mathrm{e}(-m\xi)(\xi+\chi\cdot\infty-\chi\cdot\bar{z})^{(-2\kappa)}\mathrm{d}\xi\,\mathrm{jac}(\chi,\bar{z})^{\kappa}
\end{aligned} \tag{3.1.16}$$

where the last integral in (3.1.16) is taken over the vertical line $\{\mathbf{i}t \mid t\in\mathbb{R}^+\}$. Thus, making the substitution $2\pi\mathbf{i}m\xi=t$, we find that

$$\begin{aligned}
&\int_{\chi^{-1}\rrbracket\cdot\infty}^{\infty} \mathrm{e}(-m\llbracket\chi\cdot\xi)\,\mathrm{jac}(\llbracket\chi\,,\xi)^{1-\kappa}(\xi-\bar{z})^{(-2\kappa)}\mathrm{d}\xi \\
&= -\,\mathrm{e}(-m\chi\cdot\infty)(2\pi\mathbf{i}m)^{-1}\int_{0}^{\infty} e^{-t}((2\pi\mathbf{i}m)^{-1}t+\chi\cdot\infty-\chi\cdot\bar{z})^{(-2\kappa)}\mathrm{d}t\,\mathrm{jac}(\chi,\bar{z})^{\kappa} \\
&= -\,\mathrm{e}(-m\chi\cdot\infty)\sum_{k=0}^{-2\kappa}(2\pi\mathbf{i}m)^{2\kappa-1}(2\pi\mathbf{i}(m\chi\cdot\infty-m\chi\cdot\bar{z}))^{(k)}\,\mathrm{jac}(\chi,\bar{z})^{\kappa},
\end{aligned} \tag{3.1.17}$$

and from this we deduce that

$$\left(J^{\kappa}_{\infty\cdot\llbracket\chi}P^{1-\kappa(-m)}_{\llbracket\chi}\right)(z) = m^{2\kappa-1}\,\mathrm{e}(m\chi\cdot\infty)\,\mathrm{e}(m\chi\cdot z-m\chi\cdot\infty)_{<1-2\kappa}\,\mathrm{jac}(\chi,z)^{\kappa}. \tag{3.1.18}$$

Upon comparison with (3.1.14) we obtain the required identity (3.1.13). This completes the proof. □

3.2 Coefficients

For $\llbracket\chi\rrbracket\in\llbracket G(\mathbb{Q})\rrbracket^{\times}$ and $m,n\in\mathbb{Z}$ we define a holomorphic function $s\mapsto \mathrm{Kl}^s_{\llbracket\chi\rrbracket}(m,n)$ on $\mathbb{C}$ by setting

$$\mathrm{Kl}^s_{\llbracket\chi\rrbracket}(m,n) = \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\,\mathrm{e}(-n\left\llbracket\chi^{-1}\right\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket^{s}\,. \tag{3.2.1}$$

Here $\varrho\llbracket\chi\rrbracket$ denotes the scaling factor of (2.3.11) (cf. Lemma 2.4.1). If $\chi\in G(\mathbb{Q})^{\times}$ has a preferred representative $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)$ with $c>0$, then we have

$$\mathrm{Kl}^s_{\llbracket\chi\rrbracket}(m,n) = \mathrm{e}\left(\frac{ma+nd}{c}\right)\frac{(ad-bc)^s}{c^{2s}}, \tag{3.2.2}$$

so that sums of the $\mathrm{Kl}^s_{[\![\chi]\!]}(m,n)$ over suitable subsets of $[\![G(\mathbb{Q})]\!]^\times$ recover zeta functions of various kinds, as we shall see presently. With this in mind consider the series $\mathrm{Kl}^s_S(m,n)$ defined for S a subset of $[\![G(\mathbb{Q})]\!]^\times$ by setting

$$\mathrm{Kl}^s_S(m,n) = \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \mathrm{Kl}^s_{[\![\chi]\!]}(m,n) \tag{3.2.3}$$

where $S_{\leq K}$ is as in (2.4.7). Write $\mathrm{Kl}^s_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)$ for $\mathrm{Kl}^s_S(m,n)$ in the case that $S = \left[\!\left[\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\right]\!\right]^\times$ for Γ a subgroup of $G(\mathbb{Q})$ that is commensurable with $G(\mathbb{Z})$ and $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ is a system of scaling cosets for Γ. We will verify presently (cf. Proposition 3.2.1) that the Dirichlet series $s \mapsto \mathrm{Kl}^s_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)$ converges absolutely for $\Re(s) > 1$ (so that the limit is unnecessary there) and therefore defines a holomorphic function in this region; these functions $\mathrm{Kl}^s_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)$ are among the *Selberg–Kloosterman zeta functions* introduced by Selberg in [Sel65] and shown there to admit meromorphic continuation to the entire complex plane. Selberg demonstrated further in loc. cit. that the eigenfunctions of the hyperbolic Laplacian $\Delta = (z-\bar{z})^2\partial_z\partial_{\bar{z}}$ on $\Gamma\backslash\mathbb{H}$ determine the poles of $\mathrm{Kl}^s_S(m,n)$ in such a way that a pole at s corresponds to an eigenfunction with eigenvalue $\lambda = s(1-s)$. The convergence of expressions very similar to (3.2.3) in certain regions $\Re(s) \geq \sigma$ with $\sigma \leq 1$ was considered by Knopp in [Kno86] and [Kno89][1].

Proposition 3.2.1. *Let $\Gamma < G(\mathbb{Q})$ be a group commensurable with $G(\mathbb{Z})$, let $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ be a system of scaling cosets for Γ and set $S = \left[\!\left[\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\right]\!\right]^\times$ for some $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$. Then the series (3.2.3) defining $\mathrm{Kl}^s_S(m,n)$ converges for $s = 1$ when m and n are not both zero, and converges absolutely and locally uniformly in $\Re(s) > 1$ for any $m,n \in \mathbb{Z}$.*

Proof. For positive integers r and c let S^r_c denote the subset of S consisting of double cosets $[\![\chi]\!] \in [\![G(\mathbb{Q})]\!]^\times$ with $P\det(\chi) = r$ and $c(\chi) = c$, so that $\varrho(\chi) = r/c^2$ (cf. (2.3.6)) for $[\![\chi]\!] \in S^r_c$. Observe that there are at most c elements in S^r_c so we have

$$|\,\mathrm{Kl}^s_{S^r_c}(m,n)| \leq \sum_{[\![\chi]\!]\in S^r_c} |\,\mathrm{Kl}^s_{[\![\chi]\!]}(m,n)| \leq r^s c^{1-2s} \tag{3.2.4}$$

for $s \in \mathbb{C}$. Now $S = \bigcup_{r,c>0} S^r_c$ and there are only finitely many r for which $S^r = \bigcup_{c>0} S^r_c$ is non-empty since Γ is commensurable with $G(\mathbb{Z})$, so (3.2.4) and the identity $\mathrm{Kl}^s_S(m,n) = \sum_{c>0}\sum_{r>0} \mathrm{Kl}^s_{S^r_c}(m,n)$ implies that the series of absolute values obtained from (3.2.3) is bounded above by a constant independent of m and n so long as $\Re(s) > 1$. Indeed, we have

$$|\,\mathrm{Kl}^s_S(m,n)| \leq \sum_{c>0} \sum_{r\in P\det(S)} r^\sigma c^{1-2\sigma} \leq \#P\det(S) r^\sigma_{\max} \frac{1}{2\sigma-2} \tag{3.2.5}$$

---

[1] Please note that the latter of these references contains important corrections to the former.

where $\#P\mathrm{det}(S)$ is the number of values of r for which S^r is non-empty, $r_{\max}$ is the maximum r for which S^r is non-empty, and $\sigma = \Re(s)$. This proves the required convergence of (3.2.3) in the region $\Re(s) > 1$.

We now consider convergence at $s = 1$. As mentioned above, Selberg demonstrated the meromorphic continuation of the Selberg–Kloosterman zeta function $s \to \mathrm{Kl}_S^s(m,n)$ and related its poles to the spectrum of the Laplacian on $\Gamma\backslash\mathbb{H}$ in [Sel65]. It turns out that those poles in $\Re(s) > 1/2$ are finite in number and are confined to the real line segment $(1/2, 1)$ in the case that m and n are not both zero, and the absence of a pole at $s = 1$ derives from the fact that the eigenfunctions for Δ with eigenvalue 0 are harmonic, and thus constant. (See [Iwa02], and Chapter 9 especially, for a thorough development of these ideas.) In particular, if we write $Z_{m,n}(s)$ for Selberg's meromorphic continuation of $\mathrm{Kl}_S^s(m,n)$, then $Z_{m,n}(s)$ is holomorphic at s when $\Re(s) = 1$ and m and n are not both zero, and the only pole of $Z_{0,0}(s)$ on the line $\Re(s) = 1$ is at $s = 1$. On the other hand Goldfeld–Sarnak determined the estimate

$$|Z_{m,n}(s)| = O\left(|m||n|\frac{|s|^{1/2}}{\Re(s) - 1/2}\right) \tag{3.2.6}$$

for $mn \neq 0$ as $\Im(s) \to \infty$ with $\Re(s) > 1/2$ in [GS83]. (Loc. cit. considers the case that $m, n > 0$. See [Pri00] for the extension to $mn \neq 0$, and an improvement upon (3.2.6).) Armed with this bound and the holomorphy of $Z_{m,n}(s)$ in $\Re(s) > 1 - a$ for some $a > 0$ we can deduce the convergence of (3.2.3) at $s = 1$ in the following way, which is an adaptation of the argument presented in §2 of [Kno86]. Note that we can choose $a > 0$ such that $Z_{m,n}(s)$ has no poles in $(1-a, 1)$ for all $m, n \in \mathbb{Z}$ since the values of s such that $\Re(s) > 1/2$ and $s(1-s)$ is an eigenvalue of Δ are finite in number. For such a the estimate (3.2.6) holds uniformly in s for $\Re(s) > 1 - a$.

Let $a > 0$ such that the interval $(1-a, 1)$ contains no poles of $Z_{m,n}(s)$ for any $m, n \in \mathbb{Z}$, let $T > 0$ and set C to be the positively oriented rectangular contour with corners $\pm a \pm \mathbf{i}T$. Consider the contour integral

$$I = \frac{1}{2\pi\mathbf{i}} \int_C Z_{m,n}\left(\frac{t}{2} + 1\right) x^t \frac{\mathrm{d}t}{t} \tag{3.2.7}$$

where $x > 0$. By our choice of a the integrand has a unique simple pole inside C and the residue there is $Z_{m,n}(1)$, so $I = Z_{m,n}(1)$. On the other hand the integral over the right most vertical segment of C contributes $\Sigma_T(x)$ where

$$\Sigma_T(x) = \frac{1}{2\pi\mathbf{i}} \int_{a-\mathbf{i}T}^{a+\mathbf{i}T} Z_{m,n}\left(\frac{t}{2} + 1\right) x^t \frac{\mathrm{d}t}{t}. \tag{3.2.8}$$

Observe that in the limit as $T \to \infty$ we obtain the function

$$\Sigma(x) = \lim_{T\to\infty} \Sigma_T(x) = \sum_{r>0} \sum_{0<c<x\sqrt{r}} \mathrm{Kl}^1_{S^r_c}(m,n) \tag{3.2.9}$$

(so long as x does not coincide with $c/\sqrt{r}$ for some $c, r > 0$ with S^r_c non-empty) and the difference $|\Sigma(x) - \Sigma_T(x)|$ is $O(x^a T^{-1})$ where the implied constant is independent of m and n. The estimate (3.2.6) implies that the contribution to I of the left most vertical segment of C is $O(|m||n|x^{-a}T^{1/2})$, and we may show that the contributions of the two horizontal components of C are $O(|m||n|x^a T^{1/4-1/4a})$ so long as $T < x^{4a}$ by applying the Phragmén–Lindelöf theorem (as stated in Theorem 14 of [HR64]) to the estimates $|Z_{m,n}(t/2+1)| = O(|m||n||\Im(t)|^{1/2})$ for $\Re(t) = -a$ and $|Z_{m,n}(t/2+1)| = O(1)$ for $\Re(t) = a$ (where the former of these is another application of (3.2.6) and the constant implied by the latter is independent of both m and n according to Proposition 3.2.1). Setting $T = x^{3a/2}$ we obtain

$$|\Sigma(x) - Z_{m,n}(1)| = O(|m||n|x^{-a/4}) \tag{3.2.10}$$

under the condition that $a < 3/13$, and in the limit as $x \to \infty$ we arrive at the convergence of the sum (3.2.3) at $s = 1$ in the case that $mn \neq 0$.

For the case that $mn = 0$ but $m + n \neq 0$ we note that a similar estimate to (3.2.6)

$$|Z_{m,n}(s)| = O\left(|s|^{1/2}\right) \tag{3.2.11}$$

holds uniformly in s for $\Re(s) > 1 - a$, with the implied constant independent of m and n, as a consequence of the boundedness of Fourier coefficients of non-analytic Eisenstein series in this region (cf. [Kub73]). Now the argument of the preceding paragraph goes through with (3.2.11) used in place of (3.2.6) and we obtain the desired convergence of $\mathrm{Kl}^s_S(m,n)$ at $s = 1$ for all $m, n \in \mathbb{Z}$ such that m and n are not both zero. This completes the proof of the proposition. □

Remark 3.2.2. Consider the case that $S = [\![G(\mathbb{Z})]\!]^\times$. Then the function $\mathrm{Kl}^s_S(m,n)$ is closely related to the Riemann zeta function $\zeta(s)$, for we have

$$\mathrm{Kl}^s_S(m,0) = \sum_{c\in\mathbb{Z}^+} \sum_{a\in(\mathbb{Z}/c)^*} \frac{\mathrm{e}(ma/c)}{c^{2s}} = \frac{\sigma(|m|, 1-2s)}{\zeta(2s)} \tag{3.2.12}$$

for $\Re(s) > 1$ in the case that $m < 0$, where $\sigma(n,s)$ is the divisor function of (2.2.1). In particular, the function $s \mapsto \mathrm{Kl}^{s/2}_S(1,0)$ is just the reciprocal of the Riemann zeta function when $S = [\![G(\mathbb{Z})]\!]^\times$. When $m = n = 0$ we have $\mathrm{Kl}^s_S(0,0) = \sum_{c>0} \phi(c)c^{-2s}$ where ϕ is Euler's totient function so clearly the sum diverges at $s = 1$ in this case. In general the residue of $\mathrm{Kl}^s_S(0,0)$ at $s = 1$ is the reciprocal of the hyperbolic area of the quotient $\Gamma\backslash\mathbb{H}$ when $S = [\![\Gamma]\!]^\times$ for some group Γ. (Cf. [Iwa02, §6.4].)

The following result is evident from the definition of $\mathrm{Kl}^{s}_{[\![\chi]\!]}(m,n)$, and the definition of the conjugation $\chi \mapsto \bar{\chi}$ (cf. §2.3).

Lemma 3.2.3. *For any $\chi \in G(\mathbb{Q})^{\times}$, $m,n \in \mathbb{Z}$, and $s \in \mathbb{C}$, we have*

$$\mathrm{Kl}^{s}_{[\![\chi]\!]}(m,n) = \mathrm{Kl}^{s}_{[\![\chi^{-1}]\!]}(n,m) = \mathrm{Kl}^{s}_{[\![\bar{\chi}]\!]}(-m,-n), \tag{3.2.13}$$

$$\mathrm{Kl}^{s}_{[\![\chi]\!]}(m,n)\varrho\,[\![\chi]\!]^{1-s} = \mathrm{Kl}^{1-s}_{[\![\chi]\!]}(m,n)\varrho\,[\![\chi]\!]^{s}. \tag{3.2.14}$$

For a continuous analogue of the function $\mathrm{Kl}^{s}_{[\![\chi]\!]}(m,n)$ we define $\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z)$, for $\chi \in G(\mathbb{Q})^{\times}$, $w,z \in \mathbb{C}$ and $\kappa \in \mathbb{Z}$, by setting

$$\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z) = 2\pi\mathbf{i}\,\mathrm{Res}_{\xi=0}\,\mathrm{e}\left(\frac{w\varrho\,[\![\chi]\!]}{\xi}\right)\mathrm{e}(z\xi)\,\frac{1}{\xi^{2\kappa}}\,\mathrm{d}\xi. \tag{3.2.15}$$

Lemma 3.2.4. *The function $\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z)$ admits the following series representations.*

$$\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z) = \sum_{k\geq 0}(2\pi\mathbf{i})^{2k+2\kappa}\varrho\,[\![\chi]\!]^{k}\,w^{(k)}z^{(k+2\kappa-1)} \tag{3.2.16}$$

$$\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z) = \sum_{k\geq 0}(2\pi\mathbf{i})^{2k+2-2\kappa}\varrho\,[\![\chi]\!]^{k+1-2\kappa}\,w^{(k+1-2\kappa)}z^{(k)} \tag{3.2.17}$$

The first expression (3.2.16) holds for $\kappa > 0$. The second expression (3.2.17) holds for $\kappa \leq 0$.

Lemma 3.2.5. *For any $\chi \in G(\mathbb{Q})^{\times}$ and $w,z \in \mathbb{C}$ and $\kappa \in \mathbb{Z}$ we have*

$$\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(w,z)\varrho\,[\![\chi]\!]^{\kappa} = -\,\mathrm{Bl}^{1-\kappa}_{[\![\chi]\!]}(z,w)\varrho\,[\![\chi]\!]^{1-\kappa} = -\,\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(-w,-z)\varrho\,[\![\chi]\!]^{\kappa}. \tag{3.2.18}$$

The main construction of this section is the following. Given a subset $S \subset [\![G(\mathbb{Q})]\!]^{\times}$ and $\kappa \in \mathbb{Z}$, we define the *coefficient function*, denoted $(m,n) \mapsto \mathrm{c}^{\kappa}_{S}(m,n)$, by setting

$$\mathrm{c}^{\kappa}_{S}(m,n) = \lim_{K\to\infty}\sum_{[\![\chi]\!]\in S_{\leq K}}\mathrm{Kl}^{\kappa}_{[\![\chi]\!]}(m,n)\,\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n) \tag{3.2.19}$$

(cf. (2.4.7)) whenever this limit converges. In applications we take S to be of the form $S = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ where Σ_{p} and Σ_{q} are scaling cosets for a group Γ at cusps $\mathsf{p},\mathsf{q} \in \mathsf{P}_{\Gamma}$ where Γ is commensurable with $G(\mathbb{Z})$. We will see presently that $\mathrm{c}^{\kappa}_{S}(m,n)$ converges for any such S. We obtain the following formulas by combining (3.2.1) and Lemma 3.2.4.

Lemma 3.2.6. *The coefficient functions* $\mathrm{c}^{\kappa}_{S}(m,n)$ *admit the following series representations.*

$$\mathrm{c}^{\kappa}_{S}(m,n) = \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \sum_{k\geq 0} \mathrm{e}(m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}(-n\,[\![\chi^{-1}]\!]\cdot\infty)(-4\pi^2\varrho\,[\![\chi]\!])^{k+\kappa} m^{(k)} n^{(k+2\kappa-1)} \tag{3.2.20}$$

$$\mathrm{c}^{\kappa}_{S}(m,n) = \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \sum_{k\geq 0} \mathrm{e}(m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}(-n\,[\![\chi^{-1}]\!]\cdot\infty)(-4\pi^2\varrho\,[\![\chi]\!])^{k+1-\kappa} m^{(k+1-2\kappa)} n^{(k)} \tag{3.2.21}$$

The expression (3.2.20) holds for $\kappa > 0$. *The expression (3.2.21) holds for* $\kappa \leq 0$.

Proposition 3.2.7. *For* $S \subset [\![G(\mathbb{Q})]\!]^{\times}$ *and* $m,n,\kappa\in\mathbb{Z}$ *we have*

$$\mathrm{c}^{\kappa}_{S}(m,n) = -\mathrm{c}^{1-\kappa}_{S^{-1}}(n,m) = -\mathrm{c}^{\kappa}_{\bar{S}}(-m,-n). \tag{3.2.22}$$

Proof. These identities follow directly from Lemma 3.2.6, and the observation that the values $\varrho\,[\![\chi]\!]$, $\varrho\,[\![\chi^{-1}]\!]$ and $\varrho\,[\![\bar{\chi}]\!]$ all coincide for any $\chi\in G(\mathbb{Q})^{\times}$. ☐

Proposition 3.2.8. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$ *and let* $\mathsf{p},\mathsf{q}\in\mathsf{P}_{\Gamma}$ *be cusps of* Γ. *Then the expression (3.2.19) defining the coefficient function* $\mathrm{c}^{\kappa}_{S}(m,n)$ *converges for* $S = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ *and any* $\kappa,m,n\in\mathbb{Z}$, *and further, we have*

$$|\mathrm{c}^{\kappa}_{S}(m,n)| = O\left(|m|^{1/2-\kappa}|n|^{\kappa-1/2}e^{C|mn|^{1/2}}\right) \tag{3.2.23}$$

as $|n|\to\infty$ *where* C *depends only on* S *and the implied constant depends only on* S *and* κ.

Proof. Observe that according to the $\kappa\mapsto 1-\kappa$ symmetry of Proposition 3.2.7 it suffices to consider the case that $\kappa > 0$. Observe also that for $\kappa > 0$ the coefficient function $\mathrm{c}^{\kappa}_{S}(m,n)$ vanishes for all m when $n = 0$, and when $m = 0$ we have

$$\mathrm{c}^{\kappa}_{S}(0,n) = (-4\pi^2)^{\kappa} n^{(2\kappa-1)}\,\mathrm{Kl}^{\kappa}_{S}(0,n) \tag{3.2.24}$$

according to (3.2.20), so the convergence in case $mn = 0$ is either trivial or follows from the convergence of the Selberg–Kloosterman zeta function $\mathrm{Kl}^{\kappa}_{S}(m,n)$ which is established in Proposition 3.2.1. Assume then that $mn\neq 0$. By (3.2.20) we have

$$\mathrm{c}^{\kappa}_{S}(m,n) = (-4\pi^2)^{\kappa}\sum_{c>0}\sum_{r>0}\sum_{k\geq 0}\mathrm{Kl}^{\kappa+k}_{S^{r}_{c}}(m,n)(-4\pi^2 m)^{(k)} n^{(k+2\kappa-1)} \tag{3.2.25}$$

where S^{r}_{c} is defined as in the proof of Proposition 3.2.1 and the sum over r is finite. In case

$\kappa > 1$ we can reorder the summation over k in (3.2.25) past the other two since the sum

$$\mathrm{c}^{\kappa}_{S}(m,n) = (-4\pi^2)^{\kappa} \sum_{k\geq 0} (-4\pi^2 m)^{(k)} n^{(k+2\kappa-1)} \operatorname{Kl}^{\kappa+k}_{S}(m,n) \tag{3.2.26}$$

so obtained is absolutely convergent according to the estimate (3.2.5). In detail,

$$\begin{aligned} |\mathrm{c}^{\kappa}_{S}(m,n)| &\leq (4\pi^2)^{\kappa} \sum_{k\geq 0} (4\pi^2|m|)^{(k)} |n|^{(k+2\kappa-1)} \#P\det(S) r_{\max}^{\kappa+k} \frac{1}{2\kappa-2+2k} \\ &\leq \#P\det(S)(4\pi^2 r_{\max})^{\kappa} \sum_{k\geq 0} (4\pi^2 r_{\max}|m|)^{(k)} |n|^{(k+2\kappa-1)} < \infty. \end{aligned} \tag{3.2.27}$$

Now for A and B non-negative we have

$$\sum_{k\geq 0} A^{(k)} B^{(k+2\kappa-1)} \leq A^{1/2-\kappa} B^{\kappa-1/2} \sum_{k\geq 0} (2(AB)^{1/2})^{(2k+2\kappa-1)} \tag{3.2.28}$$

so that setting $A = 4\pi^2 r_{\max}|m|$ and $B = |n|$ in (3.2.28) we obtain the required estimate (3.2.23) from (3.2.27) with $C = 4\pi r_{\max}^{1/2}$.

It remains to establish the estimate (3.2.23) in case $\kappa = 1$. For this we write

$$\mathrm{c}^{\kappa}_{S}(m,n) = (-4\pi^2)^{\kappa} n^{(2\kappa-1)} \operatorname{Kl}^{\kappa}_{S}(m,n) + \mathrm{c}^{\kappa}_{S}(m,n)_{+} \tag{3.2.29}$$

where

$$\mathrm{c}^{\kappa}_{S}(m,n)_{+} = (-4\pi^2)^{\kappa} \sum_{k>0} (-4\pi^2 m)^{(k)} n^{(k+2\kappa-1)} \operatorname{Kl}^{\kappa+k}_{S}(m,n) \tag{3.2.30}$$

is an absolutely convergent sum (cf. (3.2.26)) and we have

$$|\mathrm{c}^{\kappa}_{S}(m,n)_{+}| = O\left(|m|^{1/2-\kappa}|n|^{\kappa-1/2} e^{C|mn|^{1/2}}\right) \tag{3.2.31}$$

with $C = 4\pi r_{\max}^{1/2}$ according to the estimates (3.2.27) and (3.2.28). Now we see from (3.2.29) that the estimate (3.2.31) also holds for $\mathrm{c}^{\kappa}_{S}(m,n)$ since (3.2.6) (or (3.2.11) in case $m = 0$) implies that $\operatorname{Kl}^{\kappa}_{S}(m,n)$ has at most polynomial growth in n as $|n| \to \infty$ when $\kappa = 1$. This completes the proof. □

We write $\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)$ for $\mathrm{c}^{\kappa}_{S}(m,n)$ in the case that $S = \left[\!\left[\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\right]\!\right]^{\times}$. This notation suppresses the dependence on the choice of scaling cosets; the following lemma describes this dependence explicitly.

Lemma 3.2.9. *Let* $\mathsf{p},\mathsf{q} \in \mathsf{P}_{\Gamma}$*, let* Σ_{p} *and* Σ'_{p} *be scaling cosets for* Γ *at* p *and let* Σ_{q} *and* Σ'_{q} *be scaling cosets for* Γ *at* q*. Set* $S = \left[\!\left[\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\right]\!\right]^{\times}$ *and* $S' = \left[\!\left[(\Sigma'_{\mathsf{p}})^{-1}\Sigma'_{\mathsf{q}}\right]\!\right]^{\times}$*. Then we have* $\Sigma'_{\mathsf{p}} = \Sigma_{\mathsf{p}} T^{\alpha}$

and $\Sigma'_{\mathsf{q}} = \Sigma_{\mathsf{q}} T^{\beta}$ *and* $\mathrm{c}^{\kappa}_{S'}(m,n) = \mathrm{e}(m\alpha + n\beta)\mathrm{c}^{\kappa}_{S}(m,n)$ *for some* $\alpha, \beta \in \mathbb{Q}$.

With a fixed choice of subset $S \subset [\![G(\mathbb{Q})]\!]^{\times}$ and integer $\kappa \in \mathbb{Z}$, we assemble the coefficient functions $\mathrm{c}^{\kappa}_{S}(m,n)$ into a formal series $\tilde{F}^{\kappa}_{S}(p,q)$ by setting

$$\tilde{F}^{\kappa}_{S}(p,q) = \sum_{m,n\in\mathbb{Z}} \mathrm{c}^{\kappa}_{S}(m,n)p^m q^n. \tag{3.2.32}$$

The formal Fourier coefficients of the formal series $\tilde{F}^{\kappa}_{S}(p,q)$ with respect to the variable p are of particular importance. For fixed $S \subset [\![G(\mathbb{Q})]\!]^{\times}$ and $\kappa \in \mathbb{Z}$ we define formal series $\tilde{F}^{\kappa(m)}_{S}(q)$ by requiring that

$$\tilde{F}^{\kappa}_{S}(p,q) = \sum_{m\in\mathbb{Z}} \tilde{F}^{\kappa(m)}_{S}(q)p^m. \tag{3.2.33}$$

We define the *singular* and *regular part of* $\tilde{F}^{\kappa(m)}_{S}(q)$, to be denoted $\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{sing}}$ and $\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{reg}}$, respectively, by setting

$$\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{sing}} = \sum_{n\geq 0} \mathrm{c}^{\kappa}_{S}(m,-n-1)q^{-n-1}, \quad \tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{reg}} = \sum_{n\geq 0} \mathrm{c}^{\kappa}_{S}(m,n)q^{n}. \tag{3.2.34}$$

We define $\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{van}}$ to be the series obtained by removing the constant term from $\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{reg}}$.

$$\tilde{F}^{\kappa(m)}_{S}(q)_{\mathrm{van}} = \sum_{n>0} \mathrm{c}^{\kappa}_{S}(m,n)q^{n} \tag{3.2.35}$$

Given the formal series $\tilde{F}^{\kappa}_{S}(p,q)$ for some S and κ, one may ask if the coefficient series $\tilde{F}^{\kappa(m)}_{S}(q)$ define holomorphic functions on $\mathbb{H}$ upon the substitution of $\mathrm{e}(z)$ for q. Supposing this to be the case, we define $F^{\kappa(m)}_{S}(z)$ by setting

$$F^{\kappa(m)}_{S}(z) = \tilde{F}^{\kappa(m)}_{S}(\mathrm{e}(z)) = \sum_{n\in\mathbb{Z}} \mathrm{c}^{\kappa}_{S}(m,n)\,\mathrm{e}(nz), \tag{3.2.36}$$

and we define $F^{\kappa(m)}_{S}(z)_{\mathrm{sing}}$, $F^{\kappa(m)}_{S}(z)_{\mathrm{reg}}$ and $F^{\kappa(m)}_{S}(z)_{\mathrm{van}}$ in the analogous way.

We write $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for $F^{\kappa(m)}_{S}(z)$ in the case that $S = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ for Γ a group commensurable with $G(\mathbb{Z})$ and for $\Sigma_{\mathsf{p}}, \Sigma_{\mathsf{q}} \in \Gamma\backslash G(\mathbb{Q})$ scaling cosets for Γ at cusps $\mathsf{p}, \mathsf{q} \in \mathsf{P}_{\Gamma}$. We write $F^{(m)}_{S}(z)$ as a shorthand for $F^{0(m)}_{S}(z)$, and interpret the notation $F^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$, &c., similarly.

The regular part of the formal series $\tilde{F}^{\kappa(m)}_{S}(q)$ indeed defines a holomorphic function on $\mathbb{H}$, for suitable $\kappa, m \in \mathbb{Z}$, in the case that S is of the form $[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$.

Proposition 3.2.10. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$*, let* $\mathsf{p}, \mathsf{q} \in \mathsf{P}_{\Gamma}$ *be cusps of* Γ

and let $\kappa, m \in \mathbb{Z}$. Then the series

$$F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}} = \sum_{n>0} \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)\,\mathrm{e}(nz) \tag{3.2.37}$$

converges absolutely and locally uniformly for $z \in \mathbb{H}$. In particular, $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}$ is a holomorphic function on $\mathbb{H}$ for any $\kappa, m \in \mathbb{Z}$.

Proof. For $m \neq 0$ the claim follows directly from the estimate (3.2.23). If $m = 0$ and $\kappa \leq 0$ then $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}$ vanishes identically according to (3.2.21). For $m = 0$ and $\kappa > 0$ the required convergence of (3.2.37) follows from (3.2.24) since $\mathrm{Kl}^{\kappa}_{S}(0,n)$ has at most polynomial growth in n according to the proof of Proposition 3.2.1. □

By a similar argument to that just given we see that the singular part of the formal series $\tilde{F}^{\kappa(m)}_{S}(q)$ defines an anti-holomorphic function on $\mathbb{H}$ when S is of the form $[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$.

Proposition 3.2.11. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_{\Gamma}$ be cusps of Γ and let $\kappa, m \in \mathbb{Z}$. Then the series*

$$F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(\bar{z})_{\mathrm{sing}} = \sum_{n>0} \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,-n)\,\mathrm{e}(-n\bar{z}) \tag{3.2.38}$$

converges absolutely and locally uniformly for $z \in \mathbb{H}$. In particular, $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(\bar{z})_{\mathrm{sing}}$ is an anti-holomorphic function on $\mathbb{H}$ for any $\kappa, m \in \mathbb{Z}$.

The notation $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}$ suppresses the dependence upon the choice of scaling cosets Σ_{p} and Σ_{q}. The next result encodes this dependence precisely.

Proposition 3.2.12. *Let Γ be a group commensurable with $G(\mathbb{Z})$, and let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_{\Gamma}$. Let Σ_{p} and Σ'_{p} be scaling cosets for Γ at p and let Σ_{q} and Σ'_{q} be scaling cosets for Γ at q. Set $S = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ and $S' = [\![(\Sigma'_{\mathsf{p}})^{-1}\Sigma'_{\mathsf{q}}]\!]^{\times}$. Then we have $\Sigma'_{\mathsf{p}} = \Sigma_{\mathsf{p}}T^{\alpha}$ and $\Sigma'_{\mathsf{q}} = \Sigma_{\mathsf{q}}T^{\beta}$ and $F^{\kappa(m)}_{S'}(z) = \mathrm{e}(m\alpha)F^{\kappa(m)}_{S}(z+\beta)$ for some $\alpha, \beta \in \mathbb{Q}$.*

3.3 Convergence

Our main goal in this section is to establish the convergence, and Fourier series expansion, of the Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ (cf. §3.1), attached to a group Γ commensurable with $G(\mathbb{Z})$, and cusps p and q for Γ. We will require mostly minor modifications of the arguments furnished by Niebur in [Nie74]. An important technical tool in these arguments is the identity

$$\sum_{n>0} n^{(s-1)}\,\mathrm{e}(nz) = \sum_{n\in\mathbb{Z}} (-2\pi\mathbf{i})^{-s}(z+n)^{-s}, \tag{3.3.1}$$

valid for $\Re(s) > 1$, in which both sums converge absolutely and uniformly in z on compact subsets of $\mathbb{H}$. A nice proof of (3.3.1) appears in [KR01]. This identity can be extended to $s = 1$ at the expense of absolute convergence.

Lemma 3.3.1. *Let $z \in \mathbb{H}$ and let $K \in \mathbb{Z}^+$ such that $K + 1/2 > \Re(z)$. Then we have*

$$\sum_{n>0} \mathrm{e}(nz) = \sum_{\substack{n\in\mathbb{Z} \\ -K\leq n\leq K}} (-2\pi\mathbf{i})^{-1}(z+n)^{-1} + \lambda_K(z) \tag{3.3.2}$$

where the error term $\lambda_K(z)$ is given by

$$\lambda_K(z) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\frac{1}{z+\mathbf{i}v-K-1/2} - \frac{1}{z+\mathbf{i}v+K+1/2}\right)\frac{1}{1+e^{-2\pi v}}\mathrm{d}v. \tag{3.3.3}$$

Proof. The proof follows that of (the more general) Lemma 4.1 in [Nie74]. Define a function $f(\xi)$ by setting $f(\xi) = (2\pi\mathbf{i}\xi)^{-1}(\mathrm{e}(\xi - z) - 1)^{-1}$. Then $f(\xi)$ has a pole at $\xi = 0$ and a pole also at $\xi = z + n$ for each $n \in \mathbb{Z}$. For the residue of $f(\xi)\mathrm{d}\xi$ at $\xi = 0$ we have

$$\mathrm{Res}_{\xi=0}\, f(\xi)\mathrm{d}\xi = \frac{1}{2\pi\mathbf{i}}\frac{1}{\mathrm{e}(-z)-1} = \frac{1}{2\pi\mathbf{i}}\sum_{n>0}\mathrm{e}(nz), \tag{3.3.4}$$

which is $1/2\pi\mathbf{i}$ times the left hand side of (3.3.2), while the residue at $\xi = z+n$ is $(2\pi\mathbf{i})^{-2}(z+n)^{-1}$. Let K be a positive integer such that $K + 1/2 > \Re(z)$ and set $Q = K + 1/2$ for convenience. Let γ be the positively oriented boundary of the rectangle with corners $\Re(z) \pm Q \pm \mathbf{i}L$ where $L > \Im(z)$. Then by the residue theorem we have

$$\int_\gamma f(\xi)\mathrm{d}\xi = \sum_{n>0}\mathrm{e}(nz) + \sum_{-K\leq n\leq K}(2\pi\mathbf{i})^{-1}(z+n)^{-1}. \tag{3.3.5}$$

On the other hand, the contributions of the horizontal edges of γ to $\int_\gamma f(\xi)\mathrm{d}\xi$ tend to 0 as $L \to \infty$ since $f(\xi)$ decays exponentially as $\Im(\xi) \to \infty$. The residues are independent of L for L sufficiently large so taking the limit as $L \to \infty$ we obtain

$$\sum_{n>0}\mathrm{e}(nz) + \sum_{-K\leq n\leq K}(2\pi\mathbf{i})^{-1}(z+n)^{-1} = \lambda_K(z) \tag{3.3.6}$$

where $\lambda_K(z)$ is the limit as $L \to \infty$ of the contributions of the vertical edges of γ. Setting $x = \Re(z)$ we have

$$\lambda_K(z) = \mathbf{i}\int_{-\infty}^{\infty}(f(x+Q+\mathbf{i}v) - f(x-Q+\mathbf{i}v))\mathrm{d}v. \tag{3.3.7}$$

After replacing v with $v + \Im(z)$ and observing that $\mathrm{e}(Q) = \mathrm{e}(-Q) = -1$ since K is an integer we obtain the expression

$$\lambda_K(z) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\frac{1}{z+\mathbf{i}v-Q}-\frac{1}{z+\mathbf{i}v+Q}\right)\frac{1}{1+\mathrm{e}(\mathbf{i}v)}\mathrm{d}v \tag{3.3.8}$$

and combining this with (3.3.6) recovers the required identity. □

Setting $Q = K + 1/2$ and substituting Qv for v in (3.3.3) we find that

$$\begin{aligned}\lambda_K(z) &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\frac{1}{z/Q+\mathbf{i}v-1}-\frac{1}{z/Q+\mathbf{i}v+1}\right)\frac{1}{1+\mathrm{e}(\mathbf{i}Qv)}\mathrm{d}v\\ &= \frac{1}{\pi}\int_{-\infty}^{\infty}\frac{1}{((z/Q+\mathbf{i}v)^2-1)}\frac{1}{1+e^{-2\pi Qv}}\mathrm{d}v\end{aligned} \tag{3.3.9}$$

which demonstrates that $\lambda_K(z)$ tends to $-1/\pi$ times $\int_0^\infty(1+v^2)^{-1}\mathrm{d}v = \pi/2$ as $K\to\infty$. We thus obtain

$$\sum_{n>0}\mathrm{e}(nz) = -\frac{1}{2} + \lim_{K\to\infty}\sum_{-K<n<K}(-2\pi\mathbf{i})^{-1}(z+n)^{-1}. \tag{3.3.10}$$

The formulas (3.3.1) and (3.3.10) are collectively known as the *Lipschitz summation formula*.

Theorem 3.3.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$, and let $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m\in\mathbb{Z}$ such that $\kappa\le 0$ and $m<0$. Then the limit defining the classical Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ converges locally uniformly to a holomorphic function on $\mathbb{H}$, and we have*

$$R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + \frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0) + F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}. \tag{3.3.11}$$

Proof. Set $U = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ and $S = [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$. For $\kappa<0$ the result follows from Lemmas 4.2 and 4.3 of [Nie74]. Indeed, using Lemma 3.1.1 we may identify the Rademacher component function $R^{\kappa(m)}_{[\![\chi}(z)$ with the function $s_{[\![\chi}(z)+t_{[\![\chi}(z)$ defined on page 376 of [Nie74]. Then the expression

$$\sum_{c\in\mathbb{Z}^+}\lim_{K\to\infty}\sum_{\substack{[\![\chi\in U_{\le K}\\ c(\chi)=c}}R^{\kappa(m)}_{[\![\chi}(z) \tag{3.3.12}$$

is, up to addition by a certain constant function, the definition of Rademacher sum used by Niebur in loc. cit. The Lipschitz summation formula(s) (3.3.1) and (3.3.10) are the main tools used in equating (3.3.12) with the right hand side of (3.3.11).

In case $\kappa=0$ we require to reinforce the argument of [Nie74] with a non-trivial estimate for the Selberg–Kloosterman zeta function $\mathrm{Kl}^s_S(m,n)$ at $s=1$; we will apply the result (3.2.6) of

Goldfeld–Sarnark to this purpose. Assume then that $\kappa = 0$ and observe that we have

$$\begin{aligned} R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) &= \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + \lim_{K\to\infty} \sum_{\llbracket\chi\in U^{\times}_{\leq K}} \mathrm{e}(m\llbracket\chi\cdot\infty)\,\mathrm{e}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty, 1) \\ &= \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + \lim_{K\to\infty} \sum_{\llbracket\chi\in U^{\times}_{\leq K}} \mathrm{e}(m\llbracket\chi\cdot\infty)\sum_{k\geq 0}(-2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket)^{k+1}m^{(k+1)}(z-\chi^{-1}\rrbracket\cdot\infty)^{-k-1} \end{aligned} \tag{3.3.13}$$

according to (3.1.7), the definition (2.1.6) of the generalized exponential $\mathrm{e}(z,s)$, and the identity (2.4.4). We write $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = \mathrm{e}(mz) + R_0 + R_+$ where

$$R_0 = \lim_{K\to\infty} \sum_{\llbracket\chi\in U^{\times}_{\leq K}} \mathrm{e}(m\llbracket\chi\cdot\infty)(-2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket)m(z-\chi^{-1}\rrbracket\cdot\infty)^{-1}, \tag{3.3.14}$$

$$R_+ = \sum_{\llbracket\chi\in U^{\times}} \mathrm{e}(m\llbracket\chi\cdot\infty)\sum_{k>0}(-2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket)^{k+1}m^{(k+1)}(z-\chi^{-1}\rrbracket\cdot\infty)^{-k-1}, \tag{3.3.15}$$

and the second sum R_+ is absolutely convergent, locally uniformly for $z \in \mathbb{H}$. After choosing a representative χ for each double coset $\llbracket\chi\rrbracket$ in S we may rewrite R_+ as

$$R_+ = \sum_{\llbracket\chi\rrbracket\in S} \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\sum_{k>0}(-2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket)^{k+1}m^{(k+1)}\sum_{n\in\mathbb{Z}}(z-\chi^{-1}\rrbracket\cdot\infty+n)^{-k-1}, \tag{3.3.16}$$

and applying the Lipschitz summation formula (3.3.1) to this we obtain

$$\begin{aligned} R_+ &= \sum_{n>0}\sum_{\llbracket\chi\rrbracket\in S} \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\,\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)\sum_{k>0}(-4\pi^2\varrho\llbracket\chi\rrbracket)^{k+1}m^{(k+1)}n^{(k)}\,\mathrm{e}(nz) \\ &= \sum_{n>0}\mathrm{c}^{\kappa}_{S}(m,n)_+\,\mathrm{e}(nz) \end{aligned} \tag{3.3.17}$$

where $\mathrm{c}^{\kappa}_{S}(m,n)_+$ satisfies $\mathrm{c}^{\kappa}_{S}(m,n) = (-4\pi^2)m\,\mathrm{Kl}^{1}_{S}(m,n) + \mathrm{c}^{\kappa}_{S}(m,n)_+$ according to (3.2.21). For K a positive integer set

$$R_0(K) = (-2\pi\mathbf{i})m\sum_{U^{\times}_{\leq K}} \mathrm{e}(m\llbracket\chi\cdot\infty)\varrho\llbracket\chi\rrbracket\,(z-\chi^{-1}\rrbracket\cdot\infty)^{-1} \tag{3.3.18}$$

so that $R_0 = \lim_{K\to\infty} R_0(K)$. Then choosing as above a representative χ for each $\llbracket\chi\rrbracket \in S$ we have

$$\begin{aligned}R_0(K) &= (-2\pi\mathbf{i})m \sum_{\llbracket\chi\rrbracket\in S_{\leq K}} \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket \sum_{\substack{n\in\mathbb{Z}\\ -K^2\leq d(\chi)+nc(\chi)\leq K^2}} (z-\chi^{-1}\rrbracket\cdot\infty+n)^{-1}\\ &= (-2\pi\mathbf{i})m\sum_{0<c<K}\sum_{\llbracket\chi\rrbracket\in S_c}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket\left(\sum_{|n|\leq K^2/c}(z-\chi^{-1}\rrbracket\cdot\infty+n)^{-1}+O(c/K^2)\right)\end{aligned} \tag{3.3.19}$$

where the term $O(c/K^2)$ accounts for the discrepency between the two summations over n. Applying the Lipschitz summation formula (3.3.6) to the second line of (3.3.19) we obtain

$$R_0(K) = (-4\pi^2)m\sum_{0<c<K}\sum_{\llbracket\chi\rrbracket\in S_c}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket\left(\frac{1}{2}+\sum_{n>0}\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)\,\mathrm{e}(nz)+O(c/K^2)\right) \tag{3.3.20}$$

since the error term $\lambda_X(z)$ appearing in (3.3.6) satisfies $\lambda_X(z)+1/2=O(1/X)$. We conclude from this that

$$R_0 = \lim_{K\to\infty}\sum_{\llbracket\chi\rrbracket\in S_{\leq K}}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)(-4\pi^2)\varrho\llbracket\chi\rrbracket\, m\left(\frac{1}{2}+\sum_{n>0}\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)\,\mathrm{e}(nz)\right). \tag{3.3.21}$$

We claim now that $R_0 = \mathrm{c}^{\kappa}_S(m,0)/2+\sum_{n>0}\mathrm{c}^{\kappa}_S(m,n)_0\,\mathrm{e}(nz)$ where $\mathrm{c}^{\kappa}_S(m,n)_0 = \mathrm{c}^{\kappa}_S(m,n) - \mathrm{c}^{\kappa}_S(m,n)_+ = (-4\pi^2)m\,\mathrm{Kl}^1_S(m,n)$. To see this observe that for fixed positive K we have

$$\sum_{\llbracket\chi\rrbracket\in S_{\leq K}}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket\sum_{n>0}\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)\,\mathrm{e}(nz) = \sum_{n>0}\mathrm{Kl}^1_{S_{\leq K}}(m,n)\,\mathrm{e}(nz) \tag{3.3.22}$$

since the left hand side converges absolutely. Now $\mathrm{Kl}^1_{S_{\leq K}}(m,n) = \mathrm{Kl}^1_S(m,n)+O(n)$ as $K\to\infty$ according to (3.2.10) since the $\Sigma(x)$ there is just $\mathrm{Kl}^1_{S_{\leq x}}(m,n)$ (cf. (3.2.9)). Then (3.2.6) implies $\mathrm{Kl}^1_{S_{\leq K}}(m,n) = O(n)$ uniformly in K and n and we conclude that the limit as $K\to\infty$ of the right hand side of (3.3.22) is $\sum_{n>0}\mathrm{Kl}^1_S(m,n)\,\mathrm{e}(nz)$, and thus

$$R_0 = \mathrm{c}^{\kappa}_S(m,0)/2+\sum_{n>0}\mathrm{c}^{\kappa}_S(m,n)_0\,\mathrm{e}(nz) \tag{3.3.23}$$

as was claimed. Taking (3.3.23) together with (3.3.17) we arrive at the required identity (3.3.11) in case $\kappa=0$. The proof is complete. □

The next result identifies the Fourier series expansion of the conjugate Rademacher sum $\bar{R}^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$. As such it is a natural counterpart to Theorem 3.3.2. The method of proof is directly analogous to that of Theorem 3.3.2.

Theorem 3.3.3. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$*, and let* $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ *be cusps of* Γ*. Let* $\kappa, m\in\mathbb{Z}$ *such that* $\kappa\leq 0$ *and* $m<0$*. Then the limit defining the conjugate Rademacher sum* $\bar{R}^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ *converges locally uniformly to an anti-holomorphic function on* $\mathbb{H}$*, and we have*

$$\bar{R}^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)=\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(m\bar{z})-\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0)-F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(\bar{z})_{\mathrm{sing}}. \tag{3.3.24}$$

Theorems 3.3.2 and 3.3.3 furnish the Fourier expansions of the classical and conjugate Rademacher sums of non-positive weight. Directly analogous methods can be used to determine expressions for the Fourier coefficients of the Rademacher sums of positive weight, which are, after all, just the holomorphic Poincaré series (cf. §3.1). Indeed, there are fewer technical difficulties in the case of positive weight, since the sum appearing in the definition (3.1.2) of the Poincaré series $P^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}$ is absolutely and locally uniformly convergent (at least when $\kappa>1$). For completeness we state an analogue of Theorem 3.3.2 for $\kappa>0$. The result is standard (cf. [Iwa02]).

Theorem 3.3.4. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$*, and let* $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ *be cusps of* Γ*. Let* $\kappa,m\in\mathbb{Z}$ *such that* $\kappa>0$ *and* $m\geq 0$*. Then for* $z\in\mathbb{H}$ *we have*

$$R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)=\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz)+F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}. \tag{3.3.25}$$

Recall from §3.1 that we write $R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for $R^{0(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ and interpret $\bar{R}^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ similarly. To conclude this section we consider the difference $R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)-\bar{R}^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$. Combining Theorems 3.3.2 and 3.3.3 we obtain the following identification of the Fourier expansion of this function in terms of the exponential function $\mathrm{e}(z)$ and its conjugate $\mathrm{e}(-\bar{z})$.

Theorem 3.3.5. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$*, let* $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ *be cusps of* Γ*, and let* $m<0$*. Then we have*

$$\begin{aligned}R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)-\bar{R}^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)&=\delta_{\Gamma,\mathsf{p}|\mathsf{q}}(\mathrm{e}(mz)-\mathrm{e}(m\bar{z}))\\&\quad+F^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(\bar{z})_{\mathrm{sing}}+\mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0)+F^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}\end{aligned} \tag{3.3.26}$$

for $z\in\mathbb{H}$*.*

3.4 Variance

Recall from §3.1 that we write $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ for $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ in case q is the infinite cusp $\Gamma\cdot\infty$. Suppose that Γ is commensurable with the modular group and has width one at infinity (cf. §2.6). We will establish in this section that the Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$, once corrected by the addition of a certain constant function, is an automorphic integral of weight 2κ for Γ whenever $\kappa=1$

and $m > 0$ or $\kappa > 1$ and $m \geq 0$ or $\kappa \leq 0$ and $m < 0$. This is quite general since, according to the discussion of §3.1, any Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ can be expressed in the form $R^{\kappa(m)}_{\Gamma',\mathsf{p}'}(z)$ for some group Γ' having width one at infinity (cf. (3.1.12)).

Let us begin by considering the weight 2κ action of $G(\mathbb{Q})$ on the Rademacher component function $R^{\kappa(m)}_{\llbracket\chi}(z)$ of (3.1.4).

Lemma 3.4.1. *Let* $\llbracket\chi \in \llbracket G(\mathbb{Q})^{\times}$ *and* $\sigma \in G(\mathbb{Q})$, *and let* $\kappa, m \in \mathbb{Z}$. *In case* $\kappa > 0$ *and* $m \geq 0$ *we have*

$$\left(R^{\kappa(m)}_{\llbracket\chi} \Big|^{\kappa} \sigma \right)(z) = R^{\kappa(m)}_{\llbracket\chi\sigma}(z), \tag{3.4.1}$$

and in case $\kappa \leq 0$ *and* $m < 0$ *we have*

$$\left(R^{\kappa(m)}_{\llbracket\chi} \Big|^{\kappa} \sigma \right)(z) = R^{\kappa(m)}_{\llbracket\chi\sigma}(z) + m^{1-2\kappa} \left(J^{\kappa}_{\infty\cdot\llbracket\sigma} P^{1-\kappa(-m)}_{\llbracket\chi\sigma} \right)(z). \tag{3.4.2}$$

Proof. Note that we have

$$\left(P^{\kappa(m)}_{\llbracket\chi} |^{\kappa} \sigma \right)(z) = P^{\kappa(m)}_{\llbracket\chi\sigma}(z) \tag{3.4.3}$$

for all $\kappa, m \in \mathbb{Z}$, where $P^{\kappa(m)}_{\llbracket\chi}(z) = \mathrm{e}(m \llbracket\chi \cdot z)\,\mathrm{jac}(\llbracket\chi\,, z)^{\kappa}$ (cf. (3.1.1)), so the identity (3.4.1) follows from (3.4.3) and the fact that $R^{\kappa(m)}_{\llbracket\chi}(z) = P^{\kappa(m)}_{\llbracket\chi}(z)$ in case $\kappa > 0$, by the definition of $R^{\kappa(m)}_{\llbracket\chi}(z)$ (cf. §3.1). For (3.4.2) we suppose $\kappa \leq 0$ and $m < 0$ and use Lemma 3.1.1 to write the Rademacher component function $R^{\kappa(m)}_{\llbracket\chi}(z)$ in terms of the functions $P^{\kappa(m)}_{\llbracket\chi}(z)$ and the integral operator J^{κ}_{w}. Then, employing (3.4.3) and the identity (2.7.6), we compute

$$\begin{aligned}\left(R^{\kappa(m)}_{\llbracket\chi} \Big|^{\kappa} \sigma \right)(z) &= \left(P^{\kappa(m)}_{\llbracket\chi} \Big|^{\kappa} \sigma \right)(z) - m^{1-2\kappa} \left(\left(J^{\kappa}_{\infty\cdot\llbracket\chi} P^{1-\kappa(-m)}_{\llbracket\chi} \right) \Big|^{\kappa} \sigma \right)(z) \\ &= P^{\kappa(m)}_{\llbracket\chi\sigma}(z) - m^{1-2\kappa} \left(J^{\kappa}_{\infty\cdot\llbracket\chi\sigma} P^{1-\kappa(-m)}_{\llbracket\chi\sigma} \right)(z) + m^{1-2\kappa} \left(J^{\kappa}_{\infty\cdot\llbracket\sigma} P^{1-\kappa(-m)}_{\llbracket\chi\sigma} \right)(z).\end{aligned} \tag{3.4.4}$$

Applying Lemma 3.1.1 once again we recognize the first two terms on the right hand side (of the second line) of (3.4.4) to be $R^{\kappa(m)}_{\llbracket\chi\sigma}(z)$. We thus obtain the required identity (3.4.2). □

As for technical tools, in addition to Lemma 3.3.1, we also use the following result which shows that there is some flexibility in the convergence of the limit (3.1.6) defining the classical Rademacher sum.

Lemma 3.4.2. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$, *let* $\mathsf{p} \in \mathsf{P}_{\Gamma}$ *be a cusp of* Γ *and let* $\sigma \in G(\mathbb{Q})$. *Let* $\kappa, m \in \mathbb{Z}$ *such that either* $\kappa = 1$ *and* $m > 0$ *or* $\kappa > 1$ *and* $m \geq 0$ *or* $\kappa \leq 0$ *and*

$m < 0$. Then we have

$$\lim_{K\to\infty} \sum_{\llbracket\chi\in(U_{\leq K})\sigma} R^{\kappa(m)}_{\llbracket\chi}(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in(U\sigma)_{\leq K}} R^{\kappa(m)}_{\llbracket\chi}(z) \tag{3.4.5}$$

for $U = \llbracket\Sigma_{\mathsf{p}}^{-1}$ and $z \in \mathbb{H}$.

Proof. For $\kappa > 1$ and $m \geq 0$ both sums in (3.4.5) are absolutely convergent, and the identity certainly holds. In case $\kappa = 1$ and $m > 0$, or $\kappa \leq 0$ and $m < 0$, the identity (3.4.5) is established via the argument of Lemma 4.3 in [Nie74]. Note that this argument fails in the case that $\kappa = 1$ and $m = 0$, and indeed, the identity (3.4.5) does not hold in general when $\kappa = 1$ and $m = 0$. ☐

Theorem 3.4.3. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa > 1$ and $m \geq 0$ or $\kappa = 1$ and $m > 0$. Then the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is a modular form of weight 2κ for Γ, and is a cusp form in case $m > 0$. Further, for $\mathsf{q} \in \mathsf{P}_\Gamma$ another cusp of Γ the Fourier expansion of the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is the expansion of $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ at the cusp q.*

Proof. Let κ and m be as in the statement of the proposition. Since Γ has width one at infinity we may take Γ to be the scaling coset for Γ at the infinite cusp. Let Σ_{p} be a scaling coset for Γ at p and set $U = \llbracket\Sigma_{\mathsf{p}}^{-1}$. Then in the case that $\kappa > 1$ we have

$$R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z) = \sum_{\llbracket\chi\in U} R^{\kappa(m)}_{\llbracket\chi}(z) = \sum_{\llbracket\chi\in U} \mathrm{e}(m\,\llbracket\chi\cdot z)\,\mathrm{jac}(\llbracket\chi\,,z)^{\kappa}, \tag{3.4.6}$$

with the sum(s) in (3.4.6) converging absolutely for $z \in \mathbb{H}$. Let $\sigma \in G(\mathbb{Q})$. Then we have

$$\left(R^{\kappa(m)}_{\Gamma,\mathsf{p}}\Big|^{\kappa}\sigma\right)(z) = \sum_{\llbracket\chi\in U} \left(R^{\kappa(m)}_{\llbracket\chi}\Big|^{\kappa}\sigma\right)(z) = \sum_{\llbracket\chi\in U} R^{\kappa(m)}_{\llbracket\chi\sigma}(z) = \sum_{\llbracket\chi\in U\sigma} R^{\kappa(m)}_{\llbracket\chi}(z) \tag{3.4.7}$$

by Lemma 3.4.1, with all sums absolutely convergent, locally uniformly in z. Taking $\sigma \in \Gamma$ we see that $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is an unrestricted modular form of weight 2κ for Γ since $\Sigma_{\mathsf{p}}^{-1}\sigma = \Sigma_{\mathsf{p}}^{-1}$ for $\sigma \in \Gamma$. Taking $\mathsf{q} \in \mathsf{P}_\Gamma$ and $\sigma \in \Sigma_{\mathsf{q}}$ we see that Theorem 3.3.4 gives the Fourier expansion of $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ at q, in the sense of §2.7, since $\Sigma_{\mathsf{p}}^{-1}\sigma = \Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ for any $\sigma \in \Sigma_{\mathsf{q}}$. We conclude that the (a priori unrestricted) modular form $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is vanishing at every cusp $\mathsf{q} \in \mathsf{P}_\Gamma$, except possibly for $\mathsf{q} = \mathsf{p}$, and vanishes even there just when $m > 0$, and thus the claim is verified for $\kappa > 1$.

Consider now the case that $\kappa = 1$. We have

$$R^{1(m)}_{\Gamma,\mathsf{p}}(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} R^{1(m)}_{\llbracket\chi}(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} \mathrm{e}(m\,\llbracket\chi\cdot z)\,\mathrm{jac}(\llbracket\chi\,,z), \tag{3.4.8}$$

and it is necessary to consider (some kind of) a limit since the convergence is not absolute in this case. Let $\sigma \in G(\mathbb{Q})$ and consider the weight 2 action of σ on $R^{1(m)}_{\Gamma,\mathsf{p}}(z)$.

$$\left(R^{1(m)}_{\Gamma,\mathsf{p}}\Big|_1 \sigma\right)(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} \left(R^{1(m)}_{\llbracket\chi}\Big|_1 \sigma\right)(z) = \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} R^{1(m)}_{\llbracket\chi\sigma}(z). \tag{3.4.9}$$

Taking $\sigma \in \Gamma$ and applying Lemma 3.4.2 we see that $R^{1(m)}_{\Gamma,\mathsf{p}}(z)$ is a(n unrestricted) modular form for Γ. Applying Lemma 3.4.2 in the case that $\sigma \in \Sigma_{\mathsf{q}}$ for some cusp $\mathsf{q} \in \mathsf{P}_\Gamma$, we see that the Fourier expansion of the function $R^{1(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is the expansion of $R^{1(m)}_{\Gamma,\mathsf{p}}(z)$ at q in the sense of §2.7, so Theorem 3.3.4 applies also when $\kappa = 1$, and thus $R^{1(m)}_{\Gamma,\mathsf{p}}(z)$ is a modular form of weight 2 for Γ and even a cusp form since $m > 0$. This completes the proof. ☐

We now present an analogue of Theorem 3.4.3 for the case that $\kappa \leq 0$.

Theorem 3.4.4. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z) + \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)/2$ is an automorphic integral of weight 2κ for Γ, and for $\mathsf{q} \in \mathsf{P}_\Gamma$ another cusp of Γ the Fourier expansion of the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) + \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0)/2$ is the expansion of $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z) + \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)/2$ at the cusp q.*

Proof. Let κ and m be as in the statement of the theorem. Since Γ has width one at infinity we take Γ to be the scaling coset for Γ at the infinite cusp. Let Σ_{p} be a scaling coset for Γ at p and set $U = \llbracket\Sigma_{\mathsf{p}}^{-1}$. Let $\sigma \in G(\mathbb{Q})$. Using Lemma 3.4.1 we compute

$$\begin{aligned}\left(R^{\kappa(m)}_U\Big|^{\kappa}\sigma\right)(z) &= \lim_{K\to\infty} \sum_{\llbracket\chi\in U_{\leq K}} R^{\kappa(m)}_{\llbracket\chi\sigma}(z) + m^{1-2\kappa}\left(J^{\kappa}_{\infty\cdot\llbracket\sigma} P^{1-\kappa(-m)}_{\llbracket\chi\sigma}\right)(z)\\ &= \lim_{K\to\infty} \sum_{\llbracket\chi\in (U_{\leq K})\sigma} R^{\kappa(m)}_{\llbracket\chi}(z) + m^{1-2\kappa}\left(J^{\kappa}_{\infty\cdot\llbracket\sigma} P^{1-\kappa(-m)}_{\llbracket\chi}\right)(z)\end{aligned} \tag{3.4.10}$$

for the weight 2κ action of σ on $R^{\kappa(m)}_U(z) = R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$. Now Lemma 3.4.2 shows that

$$\left(R^{\kappa(m)}_U\Big|^{\kappa}\sigma\right)(z) = R^{\kappa(m)}_{U\sigma}(z) + m^{1-2\kappa} \lim_{K\to\infty} \sum_{\llbracket\chi\in (U_{\leq K})\sigma} \left(J^{\kappa}_{\infty\cdot\llbracket\sigma} P^{1-\kappa(-m)}_{\llbracket\chi}\right)(z), \tag{3.4.11}$$

suggesting that $R^{\kappa(m)}_U(z)$ might be an automorphic integral of weight 2κ for Γ with associated cusp form $-m^{1-2\kappa}P^{1-\kappa(-m)}_U(z)$ (cf. §2.7). This is not accurate, however, since the limit in (3.4.11) does not in general commute with the integral operator $J^{\kappa}_{\infty\cdot\llbracket\sigma}$. Rather, by the argument of Lemma 4.4. in [Nie74], we have the identity

$$\begin{aligned}\lim_{K\to\infty}\left(J^{\kappa}_{\infty\cdot[\![\sigma}\left(\sum_{[\![\chi\in(U_{\leq K})\sigma}P^{1-\kappa(-m)}_{[\![\chi}\right)\right)(z)-\left(J^{\kappa}_{\infty\cdot[\![\sigma}\left(\lim_{K\to\infty}\sum_{[\![\chi\in(U_{\leq K})\sigma}P^{1-\kappa(-m)}_{[\![\chi}\right)\right)(z)\\ =-\frac{m^{2\kappa-1}}{2}\left(\mathrm{c}^{\kappa}_{S}(m,0)\,\mathrm{jac}(\sigma,z)^{\kappa}-\mathrm{c}^{\kappa}_{S'}(m,0)\right)\end{aligned} \tag{3.4.12}$$

where $S=\{[\![\chi]\!]\mid[\![\chi\in U^{\times}\}$ and $S'=\{[\![\chi]\!]\mid[\![\chi\in(U\sigma)^{\times}\}$. Lemma 3.3.1 plays a crucial rôle in the verification of (3.4.12). Applying (3.4.12) to (3.4.11) we find that

$$\left(R^{\kappa(m)}_{U}+\frac{1}{2}\mathrm{c}^{\kappa}_{S}(m,0)\right)\Big|^{\kappa}\sigma=R^{\kappa(m)}_{U'}+\frac{1}{2}\mathrm{c}^{\kappa}_{S'}(m,0)+m^{1-2\kappa}J^{\kappa}_{\infty\cdot[\![\sigma}P^{1-\kappa(-m)}_{U'} \tag{3.4.13}$$

for $U'=U\sigma$. Taking $\sigma\in\Gamma$ and applying the identity (4.4.29) we obtain

$$\left(R^{\kappa(m)}_{\Gamma,\mathsf{p}}+\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)\right)\Big|^{\kappa}\sigma=R^{\kappa(m)}_{\Gamma,\mathsf{p}}+\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)+m^{1-2\kappa}J^{\kappa}_{\infty\cdot[\![\sigma}P^{1-\kappa(-m)}_{\Gamma,\mathsf{p}} \tag{3.4.14}$$

from (3.4.13), demonstrating that the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)+\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)/2$ is an unrestricted automorphic integral of weight 2κ for Γ with associated cusp form $-m^{1-2\kappa}P^{1-\kappa(-m)}_{\Gamma,\mathsf{p}}(z)$. Letting $\mathsf{q}\in\mathsf{P}_{\Gamma}$ and applying (3.4.13) with $\sigma\in\Sigma_{\mathsf{q}}$ we obtain

$$\begin{aligned}R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}+\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0)&=\left(R^{\kappa(m)}_{\Gamma,\mathsf{p}}+\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)\right)\Big|^{\kappa}\sigma-m^{1-2\kappa}J^{\kappa}_{\infty\cdot[\![\sigma}P^{1-\kappa(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}\\&=\left(R^{\kappa(m)}_{\Gamma,\mathsf{p}}+\frac{1}{2}\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)+m^{1-2\kappa}J^{\kappa}_{\sigma\cdot\infty}P^{1-\kappa(-m)}_{\Gamma,\mathsf{p}}\right)\Big|^{\kappa}\sigma,\end{aligned} \tag{3.4.15}$$

demonstrating that the Fourier expansion of the function $R^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)+\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0)/2$ is the expansion at q of the automorphic integral $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)+\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)/2$ in the sense of §2.7. Now Theorem 3.3.2 confirms that $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)+\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}}(m,0)/2$ is meromorphic at the cusps of Γ, and is thus an automorphic integral of weight 2κ for Γ. This completes the proof of the proposition. □

We now specialize to the case that $\kappa=0$. Our final goal in this section is to establish the Γ-invariance of the harmonic function $R^{(m)}_{\Gamma,\mathsf{p}}(z)-\bar{R}^{(m)}_{\Gamma,\mathsf{p}}(z)$ for $m<0$ in case Γ has width one at infinity. For this we utilize the spectral theory of the hyperbolic Laplacian $\Delta=(z-\bar{z})^{2}\partial_{z}\partial_{\bar{z}}$.

Consider the *Whittaker functions* $V(z,s)$ and $W(z,s)$, defined for $z,s\in\mathbb{C}$ with $z\notin\mathbb{R}$ by setting

$$V(z,s) = \mathrm{e}(z)\Gamma(s)\Phi(s,2s,z-\bar{z})(2\pi\mathbf{i}(\bar{z}-z))^s, \tag{3.4.16}$$

$$W(z,s) = \frac{\sin(\pi s)}{\sin(2\pi s)}\left(V(z,s) - V(z,1-s)\right), \tag{3.4.17}$$

in case $\Im(z) > 0$ where the function Φ is defined in (2.1.3). The values $V(z,s)$ for $\Im(z) < 0$ are obtained by imposing the symmetry $V(z,s) = V(\bar{z},s)$ and similarly for $W(z,s)$. Then $V(z,s)$ and $W(z,s)$ are eigenfunctions for Δ with eigenvalue $s(1-s)$, and the identity $V(z,1) = \mathrm{e}(\bar{z}) - \mathrm{e}(z)$ hints at a connection with the right hand side of (3.3.26). Define the *free space Green's function* $G(w,z,s)$, for $w,z \in \mathbb{H}$ with $w \neq z$ and $s \in \mathbb{C}$ such that $\Re(s) > 1$, by setting

$$G(w,z,s) = \frac{\Gamma(s)^2}{\Gamma(2s)}\,{}_2F_1\left(s,s;2s;h\right)h^s = \sum_{k\geq 0}\frac{\Gamma(k+s)^2}{\Gamma(k+2s)\Gamma(k+1)}h^{k+s}, \tag{3.4.18}$$

where ${}_2F_1(a,b;c;x)$ denotes the Gauss hypergeometric function and $h = h(w,z)$ is given as follows and depends only on the hyperbolic distance between w and z.

$$h(w,z) = \frac{(w-\bar{w})(z-\bar{z})}{(w-z)(\bar{w}-\bar{z})} = \frac{4\Im(w)\Im(z)}{|w-z|^2} \tag{3.4.19}$$

Then the function $z \mapsto G(w,z,s)$ satisfies $\Delta G(w,z,s) = s(1-s)G(w,z,s)$ and the integral operator with kernel $G(w,z,s)$ furnishes a right-inverse to the differential operator $f \mapsto (\Delta - \lambda)f$ when $\lambda = s(1-s)$.

Let Γ be a group commensurable with $G(\mathbb{Z})$, let p and q be cusps of Γ, and let Σ_{p} and Σ_{q} be scaling cosets for Γ at p and q, respectively. Define $G_{\Gamma,\mathsf{p}|\mathsf{q}}(w,z,s)$ for $w,z \in \mathbb{H}$ such that $\Gamma \cdot w \neq \Gamma \cdot z$ by setting

$$G_{\Gamma,\mathsf{p}|\mathsf{q}}(w,z,s) = \sum_{\chi \in \Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} G(w,\chi\cdot z,s). \tag{3.4.20}$$

The series (3.4.20) converges absolutely and locally uniformly when $\Re(s) > 1$ and the functions $w \mapsto G_{\Gamma,\mathsf{p}|\mathsf{q}}(w,z,s)$ and $z \mapsto G_{\Gamma,\mathsf{p}|\mathsf{q}}(w,z,s)$ are invariant for the actions of Γ^{p} and Γ^{q}, respectively. According to [Hej83] (see also [Iwa02]) we have the Fourier–Whittaker series expansion

$$\begin{split} G_{\Gamma,\mathsf{p}|\mathsf{q}}(w,z,s) = \\ \sum_{m\in\mathbb{Z}^+} G^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)W(-m\bar{w},s) + G^{(0)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)\Im(w)^{1-s} + \sum_{m\in\mathbb{Z}^+} G^{(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)W(mw,s), \end{split} \tag{3.4.21}$$

converging absolutely and locally uniformly when $\Re(s) > 1$ so long as $\Im(w) > \Im(z)$ and $\Im(z)\Im(w) > \varrho_{\Gamma,\mathsf{p}|\mathsf{q}}$, for a certain constant $\varrho_{\Gamma,\mathsf{p}|\mathsf{q}}$ depending only on Γ and p and q, where the coefficient functions $G^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ are Γ^{q}-invariant, and themselves admit the following series expansions of Poincaré type, converging absolutely for $\Re(s) > 1$ and locally uniformly for $\Im(z) > 0$.

$$G^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \frac{1}{m} \sum_{[\![\chi \in [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} V(m\,[\![\chi \cdot z, s) \tag{3.4.22}$$

$$G^{(0)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \frac{4\pi}{2s-1} \sum_{[\![\chi \in [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} \Im([\![\chi \cdot z)^{s} \tag{3.4.23}$$

$$G^{(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \frac{1}{m} \sum_{[\![\chi \in [\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} V(-m\,[\![\chi \cdot \bar{z}, s) \tag{3.4.24}$$

Let $m > 0$. Then we have the following analogue of (3.4.21) for the Green's function coefficient $G^{(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ which is again reminiscent of the right hand side of (3.3.26).

$$\begin{gathered} G^{(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\frac{1}{m}V(-m\bar{z},s) + \\ \sum_{n>0} \mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,-n,s)W(-n\bar{z},s) + \mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,0,s)\Im(z)^{1-s} + \sum_{n>0} \mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,n,s)W(nz,s) \end{gathered} \tag{3.4.25}$$

The coefficients in (3.4.25) may be defined via the following formulas, in which we assume $m, n > 0$.

$$\begin{gathered} \mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,-n,s) = \\ \frac{1}{m^{1-s}n^{s}} \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \sum_{k\geq 0} \mathrm{e}(-m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}(-n\,[\![\chi^{-1}]\!]\cdot\infty)(4\pi^2\varrho\,[\![\chi]\!])^{k+s} m^{(k)} n^{(k+2s-1)} \end{gathered} \tag{3.4.26}$$

$$\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,0,s) = \frac{1}{m^{1-s}}\frac{4\pi}{2s-1} \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \sum_{k\geq 0} \mathrm{e}(-m\,[\![\chi]\!]\cdot\infty)\varrho\,[\![\chi]\!]^{s}\,\frac{\pi^{s}}{\Gamma(s)} \tag{3.4.27}$$

$$\begin{gathered} \mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(-m,n,s) = \\ \frac{1}{m^{1-s}n^{s}} \lim_{K\to\infty} \sum_{[\![\chi]\!]\in S_{\leq K}} \sum_{k\geq 0} \mathrm{e}(-m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}(n\,[\![\chi^{-1}]\!]\cdot\infty)(-1)^{k}(4\pi^2\varrho\,[\![\chi]\!])^{k+s} m^{(k)} n^{(k+2s-1)} \end{gathered} \tag{3.4.28}$$

Comparing with Lemma (3.2.6) we obtain a direct relationship between the coefficient functions $\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n,s)$ arising from the Green's function, and the coefficient functions $\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n)$ of §3.2 which arise from the Rademacher sums.

Proposition 3.4.5. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\mathsf{p},\mathsf{q} \in \mathsf{P}_{\Gamma}$, and let $\kappa > 0$*

and $m < 0$. *Then we have the following identities for* $n > 0$.

$$\mathrm{c}^{1-\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,-n) = -m^{\kappa}n^{1-\kappa}\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,-n,\kappa) \tag{3.4.29}$$

$$\mathrm{c}^{1-\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0) = -m^{\kappa}\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,0,\kappa) \tag{3.4.30}$$

$$\mathrm{c}^{1-\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n) = -m^{\kappa}n^{1-\kappa}\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n,\kappa) \tag{3.4.31}$$

Taking $\kappa = 1$ in Proposition 3.4.5 we obtain the identity $\mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n) = -m\mathrm{g}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n,1)$ for $m < 0$, which, by Theorem 3.3.5, the series expansion (3.4.25) and the identity $W(z,1) = \mathrm{e}(z)$, may be reformulated as

$$R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) - \bar{R}^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = -mG^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,1) \tag{3.4.32}$$

for $m < 0$. The Γ^{q}-invariance of the difference $R^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) - \bar{R}^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ of classical and conjugate Rademacher sums of weight 0 now follows from the Γ^{q}-invariance of the Green's function coefficient $G^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ at $s = 1$ (cf. [Nie73]). In particular, we have the following result.

Theorem 3.4.6. *Let* Γ *be a group commensurable with* $G(\mathbb{Z})$ *that has width one at infinity, let* $\mathsf{p} \in \mathsf{P}_{\Gamma}$ *be a cusp of* Γ, *and let* $m < 0$. *Then the harmonic function* $R^{(m)}_{\Gamma,\mathsf{p}}(z) - \bar{R}^{(m)}_{\Gamma,\mathsf{p}}(z)$ *is* Γ*-invariant.*

4 Modified Rademacher sums

We have seen in §3.4 that the classical Rademacher sum $R^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ of §3 is an automorphic integral for Γ only after the addition of a particular constant function, which does not generally vanish. In this section we introduce a modification of Rademacher's construction via which the correct constant term appears naturally. Our approach employs an analytic continuation of the component functions defining the classical Rademacher sums, and entails the assignment of a Dirichlet series to each triple $(\Gamma,\mathsf{p},\mathsf{q})$ where Γ is a group commensurable with the modular group and $\mathsf{p},\mathsf{q} \in \mathsf{P}_{\Gamma}$ are cusps for Γ.

4.1 Construction

For $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$, and for $\llbracket\chi \in \llbracket G(\mathbb{Q})^{\times}$ we define the *continued Rademacher component function*, denoted $(z,s) \mapsto T^{\kappa(m)}_{\llbracket\chi}(z,s)$, by setting

$$T^{\kappa(m)}_{\llbracket\chi}(z,s) = \mathrm{e}(m\llbracket\chi\cdot z)\,\mathrm{t}^{\kappa}(m,\llbracket\chi,z,s)\,\mathrm{jac}(\llbracket\chi,z)^{\kappa} \tag{4.1.1}$$

for $z \in \mathbb{H}$ and $s \in \mathbb{C}$ such that $\Re(s) > 1$ where $\mathrm{t}^{\kappa}(m, [\![\chi\,, z, s)$ is the *continued Rademacher regularization factor of weight* 2κ which is in turn given by

$$\mathrm{t}^{\kappa}(m, [\![\chi\,, z, s) = \Phi(s - 2\kappa, 1 + s - 2\kappa, m\,[\![\chi \cdot \infty - m\,[\![\chi \cdot z)(2\pi\mathbf{i}(m\,[\![\chi \cdot z - m\,[\![\chi \cdot \infty))^{s-2\kappa} \tag{4.1.2}$$

in case $[\![\chi \in [\![G(\mathbb{Q})^{\times}$ and $\mathrm{t}^{\kappa}(m, [\![\chi\,, z, s) = 1$ otherwise. We also define a function $s \mapsto T^{\kappa(m)}_{0,[\![\chi}(s)$ by setting

$$\begin{aligned} T^{\kappa(m)}_{0,[\![\chi}(s) =\, & \mathrm{e}(m\,[\![\chi \cdot \infty)\,(2\pi\mathbf{i}(m\,[\![\chi \cdot 0 - m\,[\![\chi \cdot \infty))^{(s-2\kappa)}\,\mathrm{jac}([\![\chi\,, 0)^{\kappa} \\ & - \mathrm{e}(s/2)\,\mathrm{e}(m\,[\![\chi \cdot \infty)\,(2\pi\mathbf{i}(m\,[\![\chi \cdot \infty - m\,[\![\chi \cdot 0))^{(s-2\kappa)}\,\mathrm{jac}([\![\chi\,, 0)^{\kappa} \end{aligned} \tag{4.1.3}$$

in case $[\![\chi \in [\![G(\mathbb{Q})^{\times\times}$, and by setting $T^{\kappa(m)}_{0,[\![\chi}(s) = 0$ otherwise, and we define the *modified continued Rademacher component function*, denoted $(z, s) \mapsto Q^{\kappa(m)}_{[\![\chi}(z, s)$, by subtracting $T^{\kappa(m)}_{0,[\![\chi}(z, s)$ from $T^{\kappa(m)}_{[\![\chi}(z, s)$.

$$Q^{\kappa(m)}_{[\![\chi}(z, s) = T^{\kappa(m)}_{[\![\chi}(z, s) - T^{\kappa(m)}_{0,[\![\chi}(z, s) \tag{4.1.4}$$

Now for $U \subset [\![G(\mathbb{Q})$, and for $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$, we define the *continued Rademacher sum* $T^{\kappa(m)}_{U}(z, s)$, and the *modified continued Rademacher sum* $Q^{\kappa(m)}_{U}(z, s)$, by setting

$$T^{\kappa(m)}_{U}(z, s) = \sum_{[\![\chi \in U} T^{\kappa(m)}_{[\![\chi}(z, s), \tag{4.1.5}$$

$$Q^{\kappa(m)}_{U}(z, s) = \sum_{[\![\chi \in U} Q^{\kappa(m)}_{[\![\chi}(z, s), \tag{4.1.6}$$

and we define $T^{\kappa(m)}_{U}(z)$ and $Q^{\kappa(m)}_{U}(z)$ by taking the limit as s tends to 1 through the region $\Re(s) > 1$ in $T^{\kappa(m)}_{U}(z, s)$ and $Q^{\kappa(m)}_{U}(z, s)$, respectively, so long as these limits exist.

$$T^{\kappa(m)}_{U}(z) = \lim_{s\to 1^+} T^{\kappa(m)}_{U}(z, s) \tag{4.1.7}$$

$$Q^{\kappa(m)}_{U}(z) = \lim_{s\to 1^+} Q^{\kappa(m)}_{U}(z, s) \tag{4.1.8}$$

The function $Q^{\kappa(m)}_{U}(z)$ is the most important from the point of view of automorphy for subgroups of $G(\mathbb{Q})$, while the function $T^{\kappa(m)}_{U}(z)$ plays a special rôle in the critical case that $\kappa = 0$. We call $Q^{\kappa(m)}_{U}(z)$ the *modified Rademacher sum of weight* 2κ *and order* m *associated to* U, and we call $T^{\kappa(m)}_{U}(z)$ the *normalized Rademacher sum of weight* 2κ *and order* m *associated to* U.

Observe that we recover the Rademacher component function $R^{\kappa(m)}_{[\![\chi}(z)$ by taking $s = 1$

in either the continued Rademacher component function $T^{\kappa(m)}_{\llbracket\chi}(z,s)$ or the modified continued Rademacher component function $Q^{\kappa(m)}_{\llbracket\chi}(z,s)$.

Lemma 4.1.1. *Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$, and let $\llbracket\chi \in \llbracket G(\mathbb{Q})$. Then we have $T^{\kappa(m)}_{\llbracket\chi}(z,1) = R^{\kappa(m)}_{\llbracket\chi}(z)$ and $T^{\kappa(m)}_{0,\llbracket\chi}(1) = 0$, and hence $Q^{\kappa(m)}_{\llbracket\chi}(z,1) = R^{\kappa(m)}_{\llbracket\chi}(z)$.*

Despite the result of Lemma 4.1.1, it is generally not the case that the modified Rademacher sum $Q^{\kappa(m)}_{U}(z)$ and the classical Rademacher sum $R^{\kappa(m)}_{U}(z)$ coincide (cf. Proposition 4.4.10).

We typically take U to be of the form $U = \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ where $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ is a system of scaling cosets (cf. §2.6) for some group Γ commensurable with the modular group, and $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ are cusps of Γ. In this case we write $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for $Q^{\kappa(m)}_{U}(z)$ and $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for $T^{\kappa(m)}_{U}(z)$, suppressing the choice of scaling cosets from notation. A change in the choice of scaling cosets Σ_{p} and Σ_{q} replaces $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ with a function of the form $\mathrm{e}(\alpha)Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z+\beta)$ for some $\alpha, \beta \in \mathbb{Q}$, and similarly for $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$.

In the case that p or q is the *infinite cusp* $\Gamma\cdot\infty$ we omit it from notation, writing $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ for $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\Gamma\cdot\infty}(z)$, and $Q^{\kappa(m)}_{\Gamma|\mathsf{q}}(z)$ for $Q^{\kappa(m)}_{\Gamma,\Gamma\cdot\infty|\mathsf{q}}(z)$, and similarly for the functions $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$. The functions $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ and $T^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ are the most important, for we shall see in §4.5 that $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is an automorphic integral of weight 2κ for Γ with a single pole at the cusp p in case Γ has width one at infinity, and we will see in §4.4 that $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ and $T^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ differ only by a constant function. We call $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ the *modified Rademacher sum of weight 2κ and order m associated to Γ at the cusp* p, and we call $T^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ the *normalized Rademacher sum of weight 2κ and order m associated to Γ at the cusp* p. We shall see also in §4.5 that the Fourier expansion of the function $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is the expansion of $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ at the cusp q, in the sense of §2.7.

Just as for the classical Rademacher sums (cf. §3.1) we have the result that every modified Rademacher sum $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ may be expressed in the form $Q^{\kappa(m)}_{\Gamma',\mathsf{p}'}(z)$ for some group Γ' with width one at infinity, and some cusp p' of Γ', and similarly for the normalized Rademacher sums $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$. Precisely, we have

$$Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = Q^{\kappa(m)}_{\Gamma^{\mathsf{q}},\mathsf{p}^{\mathsf{q}}}(z) \tag{4.1.9}$$

$$T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = T^{\kappa(m)}_{\Gamma^{\mathsf{q}},\mathsf{p}^{\mathsf{q}}}(z) \tag{4.1.10}$$

subject to the understanding that the data defining the right hand sides of (4.1.9) and (4.1.10) is related to the data defining the left hand sides of (4.1.9) and (4.1.10) by $\Gamma^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{q}}$ and $\mathsf{p}^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1}\cdot\mathsf{p}$ and $\Sigma_{\mathsf{p}^{\mathsf{q}}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}$.

Our primary interest in this article is in the distinguished case that $\kappa = 0$. In order to simplify notation, and maintain consistency with the notation of §1, we write $Q^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ as a shorthand for $Q^{0(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$, and we write $T^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ as a shorthand for $T^{0(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$.

4.2 Coefficients

In order to recover explicit expressions of the Fourier coefficients of the modified Rademacher sums we employ the following generalizations of $\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n)$ and $\mathrm{c}^{\kappa}_{S}(m,n)$ for $\kappa,m,n\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0<n$. For $\kappa\leq 0$ and $m<0<n$ we define the entire function $s\mapsto \mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n,s)$ by setting

$$\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n,s)=(-1)^{\kappa}\sum_{k\geq 0}(4\pi^2)^{k-\kappa+s}\varrho\,[\![\chi]\!]^{k-2\kappa+s}\,(-m)^{(k-2\kappa+s)}n^{(k+s-1)}, \tag{4.2.1}$$

so that $\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n,1)=\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n)$. We then define the *continued coefficient function* $s\mapsto \mathrm{c}^{\kappa}_{S}(m,n,s)$ for $\kappa\leq 0$ and $m<0<n$ by setting

$$\mathrm{c}^{\kappa}_{S}(m,n,s)=\sum_{[\![\chi]\!]\in S}\mathrm{Kl}^{\kappa}_{[\![\chi]\!]}(m,n)\,\mathrm{Bl}^{\kappa}_{[\![\chi]\!]}(m,n,s). \tag{4.2.2}$$

Lemma 4.2.1. *The functions $s\mapsto \mathrm{c}^{\kappa}_{S}(m,n,s)$ admit the following series representation.*

$$\begin{aligned}&\mathrm{c}^{\kappa}_{S}(m,n,s)\\&=(-1)^{\kappa}\lim_{K\to\infty}\sum_{[\![\chi]\!]\in S_{\leq K}}\sum_{k\geq 0}\mathrm{e}(m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}(-n\,[\![\chi^{-1}]\!]\cdot\infty)(4\pi^2\varrho\,[\![\chi]\!])^{k-\kappa+s}(-m)^{(k-2\kappa+s)}n^{(k+s-1)}\end{aligned} \tag{4.2.3}$$

We have $\mathrm{c}^{\kappa}_{S}(m,n,1)=\mathrm{c}^{\kappa}_{S}(m,n)$.

We usually take S to be of the form $S=[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ where Σ_{p} and Σ_{q} are scaling cosets (cf. §2.6) for a group Γ commensurable with $G(\mathbb{Z})$ at cusps $\mathsf{p},\mathsf{q}\in\mathsf{P}_{\Gamma}$. We write $\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n,s)$ for $\mathrm{c}^{\kappa}_{S}(m,n,s)$ in the case that $S=[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$.

Utilizing the continued coefficient functions $s\mapsto \mathrm{c}^{\kappa}_{S}(m,n,s)$ we generalize the function $F^{\kappa(m)}_{S}(z)_{\mathrm{van}}$ in case $\kappa\leq 0$ and $m<0$ by setting

$$F^{\kappa(m)}_{S}(z,s)_{\mathrm{van}}=\sum_{n>0}\mathrm{c}^{\kappa}_{S}(m,n,s)\,\mathrm{e}(nz). \tag{4.2.4}$$

We write $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}}$ for $F^{\kappa(m)}_{S}(z,s)_{\mathrm{van}}$ in the case that $S=[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$ for Γ a group commensurable with $G(\mathbb{Z})$ and for $\Sigma_{\mathsf{p}},\Sigma_{\mathsf{q}}\in\Gamma\backslash G(\mathbb{Q})$ scaling cosets for Γ at cusps $\mathsf{p},\mathsf{q}\in\mathsf{P}_{\Gamma}$. We write $F^{(m)}_{S}(z,s)_{\mathrm{van}}$ as a shorthand for $F^{0(m)}_{S}(z,s)_{\mathrm{van}}$, and interpret the notation $F^{(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}}$ similarly.

We have the following analogue of Proposition 3.2.10 for the functions $F^{\kappa(m)}_{S}(z,s)_{\mathrm{van}}$ in case S is of the form $[\![\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}]\!]^{\times}$.

Proposition 4.2.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$, and let $\mathsf{p},\mathsf{q}\in\mathsf{P}_{\Gamma}$ be cusps of*

Γ. *Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the series*

$$F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}} = \sum_{n>0} \mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n,s)\,\mathrm{e}(nz) \tag{4.2.5}$$

converges absolutely and locally uniformly in z and s for $z \in \mathbb{H}$ and $\Re(s) \geq 1$. In particular, the assignment $z \mapsto F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}}$ is a holomorphic function on $\mathbb{H}$ whenever $\kappa \leq 0$ and $m < 0$ and $\Re(s) \geq 1$.

4.3 Dirichlet series

Given $[\![\chi]\!] \in [\![G(\mathbb{Q})]\!]^{\times}$, and $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$, we define a Dirichlet series $Z^{\kappa(m)}_{[\![\chi]\!]}(s)$ by setting

$$\begin{aligned} Z^{\kappa(m)}_{[\![\chi]\!]}(s) &= (-1)^{1-\kappa} \sum_{n \in \mathbb{Z}^{\times}} \mathrm{e}(m\,[\![\chi]\!] \cdot \infty)\,\mathrm{e}(-n\,[\![\chi^{-1}]\!] \cdot \infty)(4\pi^2 \varrho\,[\![\chi]\!])^{1-s-\kappa} |m|^{(1-s-2\kappa)} n^{(-s)} \\ &= (-1)^{1-\kappa}\,\mathrm{e}(m\,[\![\chi]\!] \cdot \infty)(4\pi^2 \varrho\,[\![\chi]\!])^{1-s-\kappa} |m|^{(1-s-2\kappa)} \sum_{n \in \mathbb{Z}^{\times}} \mathrm{e}(-n\,[\![\chi^{-1}]\!] \cdot \infty) n^{(-s)}. \end{aligned} \tag{4.3.1}$$

(Recall that $\mathbb{Z}^{\times}$ denotes the non-zero elements of $\mathbb{Z}$.) This series (4.3.1) converges absolutely and locally uniformly in the half plane $\Re(s) > 1$, and admits a meromorphic continuation to all of $\mathbb{C}$. Given $S \subset [\![G(\mathbb{Q})]\!]^{\times}$ we define the *zeta function of weight 2κ and order m associated to S*, to be denoted $Z^{\kappa(m)}_{S}(s)$, by setting

$$Z^{\kappa(m)}_{S}(s) = \sum_{[\![\chi]\!] \in S} Z^{\kappa(m)}_{[\![\chi]\!]}(s). \tag{4.3.2}$$

As it is defined here $Z^{\kappa(m)}_{S}$ is only a formal sum but it will be shown to converge, and admit an analytic continuation, for various choices of S in §4.4 (cf. Proposition 4.4.4, Theorem 4.4.5). In order to describe the analytic continuation of the zeta function $s \mapsto Z^{\kappa(m)}_{S}(s)$ explicitly, we formulate an identity which expresses it in terms of the Hurwitz zeta function. In preparation for this we define a function $s \mapsto \tilde{Z}^{\kappa(m)}_{[\![\chi]\!]}(s)$, for each $[\![\chi]\!] \in [\![G(\mathbb{Q})]\!]^{\times}$, by setting

$$\tilde{Z}^{\kappa(m)}_{[\![\chi]\!]}(s) = \mathrm{e}(m\,[\![\chi]\!] \cdot \infty)\varrho\,[\![\chi]\!]^{s-\kappa}\,(-2\pi\mathbf{i}m)^{(s-2\kappa)}(\mathrm{e}(s/2) - \mathrm{e}(-s/2))\zeta(1 - \alpha_{[\![\chi]\!]}, s) \tag{4.3.3}$$

where $\zeta(\alpha, s)$ is defined by $\zeta(\alpha, s) = \sum_{n \geq 0}(n+\alpha)^{-s}$ for $\Re(\alpha) > 0$ and $\Re(s) > 1$, and $\alpha_{[\![\chi]\!]} \in \mathbb{Q}$ is chosen so that

$$0 \leq \alpha_{[\![\chi]\!]} < 1, \quad \alpha_{[\![\chi]\!]} + \mathbb{Z} = -\chi^{-1} \cdot \infty + \mathbb{Z}. \tag{4.3.4}$$

We then define $\tilde{Z}^{\kappa(m)}_S(s)$ by setting $\tilde{Z}^{\kappa(m)}_S(s)=\sum_{[\![\chi]\!]\in S}\tilde{Z}^{\kappa(m)}_{[\![\chi]\!]}(s)$.

Lemma 4.3.1. *We have* $Z^{\kappa(m)}_S(1-s)=\tilde{Z}^{\kappa(m)}_S(s)$.

Proof. Let $[\![\chi]\!]\in[\![G(\mathbb{Q})]\!]^\times$ and choose $\alpha_{[\![\chi]\!]}\in\mathbb{Q}$ such that $0\leq\alpha_{[\![\chi]\!]}<1$ and $\alpha_{[\![\chi]\!]}+\mathbb{Z}=-\chi^{-1}\cdot\infty+\mathbb{Z}$ for any $\chi\in[\![\chi]\!]$. We will show that $Z^{\kappa(m)}_{[\![\chi]\!]}(s)=\tilde{Z}^{\kappa(m)}_{[\![\chi]\!]}(1-s)$. Observe that we have

$$\sum_{n\in\mathbb{Z}^\times}\mathrm{e}(-n\left[\!\left[\chi^{-1}\right]\!\right]\cdot\infty)n^{(-s)}=\frac{1}{\Gamma(1-s)}\left(F\left(-\left[\!\left[\chi^{-1}\right]\!\right]\cdot\infty,s\right)+\mathrm{e}(-s/2)F\left(\left[\!\left[\chi^{-1}\right]\!\right]\cdot\infty,s\right)\right),\tag{4.3.5}$$

where $F(\alpha,s)$ denotes the periodic zeta function, defined by $F(\alpha,s)=\sum_{n>0}\mathrm{e}(n\alpha)n^{-s}$ for $\Re(s)>1$. The *Hurwitz relation*, which may be stated in the form

$$F(\alpha,s)+\mathrm{e}(-s/2)F(-\alpha,s)=\frac{(-2\pi\mathbf{i})^s}{\Gamma(s)}\zeta(1-\alpha,1-s)\tag{4.3.6}$$

(cf. [KR01]) implies the identity

$$\sum_{n\in\mathbb{Z}^\times}\mathrm{e}(-n\left[\!\left[\chi^{-1}\right]\!\right]\cdot\infty)n^{(-s)}=\frac{(-2\pi\mathbf{i})^s}{\Gamma(1-s)\Gamma(s)}\zeta(1-\alpha_{[\![\chi]\!]},1-s),\tag{4.3.7}$$

so the expression (4.3.1) may be reformulated as

$$Z^{\kappa(m)}_{[\![\chi]\!]}(s)=(-1)^{1-\kappa}\,\mathrm{e}(m\,[\![\chi]\!]\cdot\infty)(4\pi^2\varrho\,[\![\chi]\!])^{1-s-\kappa}|m|^{(1-s-2\kappa)}\frac{(-2\pi\mathbf{i})^s}{\Gamma(1-s)\Gamma(s)}\zeta(1-\alpha_{[\![\chi]\!]},1-s).\tag{4.3.8}$$

We obtain the coincidence of the right hand side of (4.3.8) with $\tilde{Z}^{\kappa(m)}_{[\![\chi]\!]}(1-s)$ by applying the functional equation for the Gamma function, which may be expressed as

$$(\mathrm{e}(s/2)-\mathrm{e}(-s/2))\Gamma(s)\Gamma(1-s)=2\pi\mathbf{i}\tag{4.3.9}$$

This completes the proof of the claim. □

We write $Z^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(s)$ for $Z^{\kappa(m)}_S(s)$ in the case that $S=\left[\!\left[\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\right]\!\right]^\times$ for Γ a group commensurable with $G(\mathbb{Z})$ and for $\Sigma_{\mathsf{p}},\Sigma_{\mathsf{q}}\in\Gamma\backslash G(\mathbb{Q})$ scaling cosets for Γ at cusps $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$.

4.4 Convergence

Our main objective in this section is to furnish explicit expressions for the Fourier expansions of the functions $z\mapsto T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ and $z\mapsto Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$, defined by the continued Rademacher sums and modified continued Rademacher sums, respectively. This will yield the Fourier expansions of the modified Rademacher sums $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ and the normalized Rademacher sums $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$. In preparation for the derivation of these expansions we verify the absolute and locally uniform convergence of the series defining $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ and $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ in case $\Re(s) > 1$.

Proposition 4.4.1. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the continued Rademacher sum*

$$T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \sum_{\llbracket\chi \in \llbracket\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}} T^{\kappa(m)}_{\llbracket\chi}(z,s) \tag{4.4.1}$$

is absolutely convergent, locally uniformly in z and s, for $z \in \mathbb{H}$ and $\Re(s) > 1$.

Proof. We begin by observing that we have

$$T^{\kappa(m)}_{\llbracket\chi}(z,s) = \mathrm{e}(m\llbracket\chi\cdot\infty)\,\mathrm{e}(m\llbracket\chi\cdot z - m\llbracket\chi\cdot\infty, s-2\kappa)\,\mathrm{jac}(\llbracket\chi\,,z)^\kappa \tag{4.4.2}$$

in case $\llbracket\chi \in \llbracket G(\mathbb{Q})^\times$, and $T^{\kappa(m)}_{\llbracket\chi}(z,s) = \mathrm{e}(m\llbracket\chi\cdot z)\,\mathrm{jac}(\llbracket\chi\,,z)^\kappa$ otherwise, where $\mathrm{e}(z,s)$ denotes the generalized exponential function of (2.1.6). This identity (4.4.2) follows from an application of the *Kummer transformation* $\Phi(a,b,z) = \mathrm{e}(z)\Phi(b-a,b,-z)$ to the expression (4.1.1) defining $T^{\kappa(m)}_{\llbracket\chi}(z,s)$. The absolute and locally uniform convergence of (4.4.1) can be established by implementing methods present in the proofs of Proposition 3.2.8 and Theorem 3.3.2. Namely, the right hand side of (4.4.1) is very similar to the quantity R_+ defined in (3.3.15) and we can rewrite it so as to arrive at an analogue of (3.3.17). Then the coefficients of $\mathrm{e}(nz)$ in the resulting sum can be estimated just as the values $\mathrm{c}^\kappa_S(m,n)$ are in (3.2.27) for $\kappa > 1$. □

Proposition 4.4.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the sum*

$$\sum_{\llbracket\chi \in \llbracket\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{q}} T^{\kappa(m)}_{0,\llbracket\chi}(s) \tag{4.4.3}$$

is absolutely convergent, locally uniformly in s, for $\Re(s) > 1$.

Propositions 4.4.1 and 4.4.2 imply the absolute and locally uniform convergence of the expression defining the modified continued Rademacher sum $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ for $z \in \mathbb{H}$ and $\Re(s) > 1$.

Proposition 4.4.3. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ, and let Σ_p and Σ_q be scaling cosets for Γ at p and q, respectively. Let $\kappa \in \mathbb{Z}$ such that $\kappa \leq 0$,* *and let $m \in \mathbb{Z}^+$. Then the modified Rademacher sum*

$$Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \sum_{\llbracket\chi \in \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} T^{\kappa(m)}_{\llbracket\chi}(z,s) - T^{\kappa(m)}_{0,\llbracket\chi}(s) \tag{4.4.4}$$

converges absolutely, and locally uniformly in z and s, for $z \in \mathbb{H}$ and $\Re(s) > 1$.

We next seek to relate the modified Rademacher sums $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ to the functions $F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$ and $Z^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(s)$ of §4.2 and §4.3, respectively.

Proposition 4.4.4. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ, with scaling matrices Σ_{p} and Σ_{q}, respectively. Let $\kappa \in \mathbb{Z}$ such that $\kappa \leq 0$ and let $m \in \mathbb{Z}^+$. Then we have*

$$\sum_{\llbracket\chi \in \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}} T^{\kappa(m)}_{0,\llbracket\chi}(s) = -Z^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(1-s) \tag{4.4.5}$$

for $\Re(s) > 1$ where the convergence is absolute and locally uniform.

Proof. Set $U = \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ and $S = \llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\rrbracket^{\times}$. Recall that $T^{\kappa(m)}_{0,\llbracket\chi}(s) = 0$ when $\llbracket\chi \notin \llbracket G(\mathbb{Q})^{\times\times}$, and otherwise

$$\begin{aligned} T^{\kappa(m)}_{0,\llbracket\chi}(s) = {}& \mathrm{e}(m\llbracket\chi\cdot\infty)\,(2\pi\mathbf{i}(m\llbracket\chi\cdot 0 - m\llbracket\chi\cdot\infty))^{(s-2\kappa)}\,\mathrm{jac}(\llbracket\chi\,,0)^{\kappa} \\ & - \mathrm{e}(s/2)\,\mathrm{e}(m\llbracket\chi\cdot\infty)\,(2\pi\mathbf{i}(m\llbracket\chi\cdot\infty - m\llbracket\chi\cdot 0))^{(s-2\kappa)}\,\mathrm{jac}(\llbracket\chi\,,0)^{\kappa}, \end{aligned} \tag{4.4.6}$$

by the definition (cf. §4.1) of $T^{\kappa(m)}_{0,\llbracket\chi}(s)$. We apply the identities $\chi\cdot\infty - \chi\cdot 0 = \varrho(\chi)/(-\chi^{-1}\cdot\infty)$ and $\mathrm{jac}(\llbracket\chi\,,0) = \varrho(\chi)/(-\chi^{-1}\cdot\infty)^2$ (cf. §2.4) so as to write

$$T^{\kappa(m)}_{0,\llbracket\chi}(s) = \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket^{s-\kappa}(-2\pi\mathbf{i}m)^{(s-2\kappa)}((-\chi^{-1}\rrbracket\cdot\infty)^{-s} - \mathrm{e}(s/2)(\chi^{-1}\rrbracket\cdot\infty)^{-s}). \tag{4.4.7}$$

Let $\llbracket\chi\rrbracket \in \llbracket G(\mathbb{Q})\rrbracket^{\times}$. Then we have

$$\sum_{\llbracket\chi \in \llbracket\chi\rrbracket} T^{\kappa(m)}_{0,\llbracket\chi}(s) = \mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket^{s-\kappa}(-2\pi\mathbf{i}m)^{(s-2\kappa)}\sideset{}{^*}\sum_{n\in\mathbb{Z}}((n+\alpha_{\llbracket\chi\rrbracket})^{-s} - \mathrm{e}(s/2)(n-\alpha_{\llbracket\chi\rrbracket})^{-s}) \tag{4.4.8}$$

where $\alpha_{\llbracket\chi\rrbracket} \in \mathbb{Q}$ is chosen so that $0 \leq \alpha_{\llbracket\chi\rrbracket} < 1$ and $\alpha_{\llbracket\chi\rrbracket} + \mathbb{Z} = -\chi^{-1}\cdot\infty + \mathbb{Z}$, and the superscript in the summation $\sum^*_{n\in\mathbb{Z}}$ indicates to omit the term corresponding to $n = 0$ in case $\alpha_{\llbracket\chi\rrbracket} = 0$.

We compute

$$\sum_{n\in\mathbb{Z}}^{*}((n+\alpha_{\llbracket\chi\rrbracket})^{-s}-\mathrm{e}(s/2)(n-\alpha_{\llbracket\chi\rrbracket})^{-s})=(\mathrm{e}(-s/2)-\mathrm{e}(s/2))\zeta(1-\alpha_{\llbracket\chi\rrbracket},s) \tag{4.4.9}$$

where $\zeta(\alpha,s)$ denotes the Hurwitz zeta function (cf. §4.3), so we have

$$\sum_{\llbracket\chi\in U^{\times\times}}T^{\kappa(m)}_{0,\llbracket\chi}(s)=\sum_{\llbracket\chi\rrbracket\in S^{\times}}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\varrho\llbracket\chi\rrbracket^{s-\kappa}(-2\pi\mathbf{i}m)^{(s-2\kappa)}(\mathrm{e}(-s/2)-\mathrm{e}(s/2))\zeta(1-\alpha_{\llbracket\chi\rrbracket},s). \tag{4.4.10}$$

Comparing with the expression (4.3.3) defining $Z^{\kappa(m)}_{\llbracket\chi\rrbracket}(s)'$ we see that the right hand side of (4.4.10) coincides with $-Z^{\kappa(m)}_{S^{\times}}(s)'$. Now Lemma 4.3.1 yields the required identity (4.4.5). This completes the proof. ☐

Theorem 4.4.5. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p},\mathsf{q}\in\mathsf{P}_{\Gamma}$ be cusps of Γ. Let $\kappa,m\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0$. Then we have*

$$Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)=\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(-mz)+Z^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(1-s)+F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}} \tag{4.4.11}$$

for $z\in\mathbb{H}$ and $\Re(s)>1$.

Proof. Let $m<0<\kappa$, let $s\in\mathbb{C}$ with $\Re(s)>1$, set $U=\llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ and set $S=\llbracket\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}\rrbracket^{\times}$. By the defining properties of scaling cosets (cf. §2.6) and by the definition (4.1.1) of the continued Rademacher component function $T^{1-\kappa(m)}_{\llbracket\chi}(z,s)$ we have

$$\sum_{\llbracket\chi\in U}T^{1-\kappa(m)}_{\llbracket\chi}(z,s)=\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz)+\sum_{\llbracket\chi\in U^{\times}}T^{1-\kappa(m)}_{\llbracket\chi}(z,s) \tag{4.4.12}$$

so by Proposition 4.4.4, and the definition of the modified continued Rademacher component function $Q^{1-\kappa(m)}_{\llbracket\chi}(z,s)$, it suffices for us to show that

$$\sum_{\llbracket\chi\in U^{\times}}T^{1-\kappa(m)}_{\llbracket\chi}(z,s)=F^{1-\kappa(m)}_{S}(z,s)_{\mathrm{van}}. \tag{4.4.13}$$

We will verify the equality of (4.4.13) by using the Lipschitz summation formula (3.3.1) to transform the expression on the right hand side of (4.4.13) into that on the left. This is essentially the approach employed originally by Rademacher in [Rad39], and the reverse of that employed by Niebur in Lemma 4.2 of [Nie74], except that we can avoid the technical difficulties of [Rad39] and [Nie74], such as the need to employ the identity (3.3.10), by working only with the versions of the Lipschitz summation formula (viz., $\Re(s)>1$) in which both sides of the identity are absolutely and locally uniformly convergent series.

We begin by inspecting Lemma 4.2.1 to find that

$$\begin{aligned}&(-1)^{1-\kappa}\mathrm{c}_S^{1-\kappa}(m,n,s)\\&=\sum_{\llbracket\chi\rrbracket\in S}\sum_{k\geq 0}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\,\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)(4\pi^2\varrho\llbracket\chi\rrbracket)^{k+\kappa+s-1}|m|^{(k+2\kappa+s-2)}n^{(k+s-1)},\end{aligned}\tag{4.4.14}$$

As a shorthand let us set $F_{\mathrm{van}}=F_S^{1-\kappa(m)}(z,s)_{\mathrm{van}}$. Then we have the following expression for F_{van} as a triple sum

$$\begin{aligned}&(-1)^{1-\kappa}F_{\mathrm{van}}=\\&\sum_{n>0}\sum_{\llbracket\chi\rrbracket\in S}^{\lim}\sum_{k\geq 0}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\,\mathrm{e}(-n\llbracket\chi^{-1}\rrbracket\cdot\infty)(4\pi^2\varrho\llbracket\chi\rrbracket)^{k+\kappa+s-1}|m|^{(k+2\kappa+s-2)}n^{(k+s-1)}\,\mathrm{e}(nz)\end{aligned}\tag{4.4.15}$$

where $\sum_{\llbracket\chi\rrbracket\in S}^{\lim}$ is a shorthand for $\lim_{K\to\infty}\sum_{\llbracket\chi\rrbracket\in S_{\leq K}}$. We now move the summation over n past the other two summations, simultaneously pulling the terms $\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)$ outside the summation over k, and combining the exponents involving n. We thus obtain

$$\begin{aligned}&(-1)^{1-\kappa}F_{\mathrm{van}}=\\&\sum_{\llbracket\chi\rrbracket\in S}^{\lim}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\sum_{k\geq 0}(4\pi^2\varrho\llbracket\chi\rrbracket)^{k+\kappa+s-1}|m|^{(k+2\kappa+s-2)}\sum_{n>0}n^{(k+s-1)}\,\mathrm{e}(n(z-\llbracket\chi^{-1}\rrbracket\cdot\infty)).\end{aligned}\tag{4.4.16}$$

Applying the Lipschitz summation formula (3.3.1) to each summation over n in (4.4.16) we find that

$$\begin{aligned}&(-1)^{1-\kappa}F_{\mathrm{van}}=\\&\sum_{\llbracket\chi\rrbracket\in S}^{\lim}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)\sum_{k\geq 0}(4\pi^2\varrho\llbracket\chi\rrbracket)^{\kappa-1}|m|^{(k+2\kappa+s-2)}\sum_{n\in\mathbb{Z}}(2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket)^{k+s}(z+n-\chi^{-1}\rrbracket\cdot\infty)^{-k-s}\end{aligned}\tag{4.4.17}$$

where $\chi^{-1}\rrbracket$ is any (left) coset of $B(\mathbb{Z})$ in the double coset $\llbracket\chi^{-1}\rrbracket$, for each $\llbracket\chi\rrbracket\in S$. Using the identity (2.4.5) we write F_{van} as $F_{\mathrm{van}}=\sum_{\llbracket\chi\rrbracket\in S}^{\lim}\mathrm{e}(m\llbracket\chi\rrbracket\cdot\infty)F_{\mathrm{van},\llbracket\chi\rrbracket}$ where

$$F_{\mathrm{van},\llbracket\chi\rrbracket}=\sum_{k\geq 0}\sum_{n\in\mathbb{Z}}(-2\pi\mathbf{i}\varrho\llbracket\chi\rrbracket\,m)^{k+2\kappa+s-2}(z+n-\chi^{-1}\rrbracket\cdot\infty)^{-k-2\kappa-s+2}\,\mathrm{jac}(\llbracket\chi\,,z+n)^{1-\kappa}.\tag{4.4.18}$$

Recalling the definition of the generalized exponential function $\mathrm{e}(z,s)$ from (2.1.6) we see that

$$F_{\mathrm{van}} = \sum_{[\![\chi \in U^{\times}} \mathrm{e}(m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}\left(\frac{-\varrho\,[\![\chi]\!]\,m}{z-\chi^{-1}]\!]\cdot\infty}, s-2(1-\kappa)\right)\mathrm{jac}([\![\chi\ , z)^{1-\kappa}. \tag{4.4.19}$$

According to (2.4.4) we have $\varrho\,[\![\chi]\!]\,/(z-\chi^{-1}\cdot\infty) = \chi\cdot\infty - \chi\cdot z$. Using this identity together with the Kummer transformation $\Phi(a,b,z) = \mathrm{e}(z)\Phi(b-a,b,-z)$ (cf. (2.1.3)) we readily find that

$$\mathrm{e}(m\,[\![\chi]\!]\cdot\infty)\,\mathrm{e}\left(\frac{-\varrho\,[\![\chi]\!]\,m}{z-\chi^{-1}]\!]\cdot\infty}, s-2(1-\kappa)\right) = \mathrm{e}(m\,[\![\chi]\!]\cdot z)\,\mathrm{t}^{1-\kappa}(m,[\![\chi\ ,z,s), \tag{4.4.20}$$

so that we have

$$F_{\mathrm{van}} = \sum_{[\![\chi\in U^{\times}} T^{1-\kappa(m)}_{[\![\chi}(z,s). \tag{4.4.21}$$

This establishes the required identity (4.4.13). □

In the course of proving Theorem 4.4.5 we have also established the Fourier expansion of the continued Rademacher sums $T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$. We record the result as follows.

Theorem 4.4.6. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0$. Then we have*

$$T^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + F^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)_{\mathrm{van}} \tag{4.4.22}$$

for $z\in\mathbb{H}$ and $\Re(s)>1$.

Theorem 4.4.5 will facilitate the identification of the Fourier expansion of the modified Rademacher sum $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ obtained by sending s to 1 in $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z,s)$. Indeed, we will see presently (cf. Proposition 4.4.8) that the series $\tilde{F}^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(q)_{\mathrm{reg}}$ encodes the regular part of the fourier series expansion of $Q^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ precisely, in the case that $\kappa\leq 0$. In preparation for this we state the following result which identifies the value of the zeta function $Z^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(s)$ at $s=0$.

Proposition 4.4.7. *Let $S\subset[\![G(\mathbb{Q})]\!]^{\times}$, let $\kappa,m\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0$. Then we have*

$$Z^{\kappa(m)}_{S}(0) = \mathrm{c}^{\kappa}_{S}(m,0). \tag{4.4.23}$$

Proof. According to the proof of Lemma 4.3.1 the function $\Gamma(s)Z^{\kappa(m)}_{[\![\chi]\!]}(s)$ coincides with

$$(-1)^{1-\kappa}\,\mathrm{e}(m\,[\![\chi]\!]\cdot\infty)(4\pi^2\varrho\,[\![\chi]\!])^{1-s-\kappa}|m|^{(1-s-2\kappa)}(F(\alpha_{[\![\chi]\!]},s)+\mathrm{e}(-s/2)F(-\alpha_{[\![\chi]\!]},s)) \tag{4.4.24}$$

where $0 \leq \alpha_{[\![\chi]\!]} < 1$ and $\alpha_{[\![\chi]\!]} + \mathbb{Z} = -\chi^{-1} \cdot \infty + \mathbb{Z}$. We have $F(\alpha, 0) + F(-\alpha, 0) = -1$ for $\alpha \in \mathbb{R}$ (cf. [KR01]), so taking $s = 0$ in (4.4.24) we obtain

$$Z_{[\![\chi]\!]}^{\kappa(m)}(0) = \mathrm{e}(m\,[\![\chi]\!] \cdot \infty)(-4\pi^2 \varrho\,[\![\chi]\!])^{1-\kappa} m^{(1-2\kappa)}. \tag{4.4.25}$$

Upon inspection of (3.2.21) we see that

$$\mathrm{c}_S^{\kappa}(m, 0) = \sum_{[\![\chi]\!] \in S} \mathrm{e}(m\,[\![\chi]\!] \cdot \infty)(-4\pi^2 \varrho\,[\![\chi]\!])^{1-\kappa} m^{(1-2\kappa)} \tag{4.4.26}$$

for $\kappa \leq 0$, and the claim now follows since $Z_S^{\kappa(m)}(s) = \sum_{[\![\chi]\!] \in S} Z_{[\![\chi]\!]}^{\kappa(m)}(s)$ by definition. □

Proposition 4.4.8. *Let Γ be a group commensurable with $G(\mathbb{Z})$, and let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then we have*

$$Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)_{\mathrm{reg}} \tag{4.4.27}$$

for $z \in \mathbb{H}$.

Proof. We take the limit as s tends to 1 in the right hand side of the identity (4.4.11). We have $F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z, 1)_{\mathrm{van}} = F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)_{\mathrm{van}}$ by definition (cf. §4.2), and we have $Z_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(0) = \mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa}(m, 0)$ by Proposition 4.4.7. The required identity (4.4.27) now follows from the fact that $F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)_{\mathrm{reg}} = \mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa}(m, 0) + F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)_{\mathrm{van}}$, also by definition (cf. §3.2). □

The proof of Proposition 4.4.8 implies a result analogous to (4.4.27) for the normalized Rademacher sum $T_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$.

Proposition 4.4.9. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then we have*

$$T_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(mz) + F_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)_{\mathrm{van}} \tag{4.4.28}$$

for $z \in \mathbb{H}$.

We may compare the functions $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ and $R_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ defined by the modified and classical Rademacher sums, respectively. Inspecting Theorem 3.3.2 and Proposition 4.4.8 we obtain the precise relationship, which we record in the following proposition.

Proposition 4.4.10. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then we have*

$$Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z) = R_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z) + \frac{1}{2}\mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa}(m, 0). \tag{4.4.29}$$

According to Propositions 4.4.8 and 4.4.9 the modified Rademacher sum $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ and the normalized Rademacher sum $T_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ also differ only by a constant function.

Proposition 4.4.11. *Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ be cusps of Γ. Let $\kappa,m\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0$. Then we have*

$$Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)=T_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)+\mathrm{c}_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa}(m,0). \tag{4.4.30}$$

4.5 Variance

In this section we examine how the modified Rademacher sum $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ transforms under the weight 2κ action of Γ. Combining Theorem 3.4.4 and Proposition 4.4.10 we obtain the result that the modified Rademacher sum $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ is an automorphic integral of weight 2κ for Γ in case Γ has width one at infinity.

Theorem 4.5.1. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p}\in\mathsf{P}_\Gamma$ be a cusp of Γ. Let $\kappa,m\in\mathbb{Z}$ such that $\kappa\leq 0$ and $m<0$. Then the modified Rademacher sum $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ is an automorphic integral of weight 2κ for Γ, and for $\mathsf{q}\in\mathsf{P}_\Gamma$ another cusp of Γ the Fourier expansion of the function $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z)$ is the expansion of $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ at the cusp q.*

The proof of Theorem 3.4.4 yields the following explicit description of the associated cusp form map $I_\kappa(\Gamma)\to S_{1-\kappa}(\Gamma)$ on the subspace of $I_\kappa(\Gamma)$ spanned by the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$.

Proposition 4.5.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p}\in\mathsf{P}_\Gamma$ be a cusp of Γ. Let $\kappa,m\in\mathbb{Z}$ such that $\kappa\leq 0<m$. Then*

$$m^{\kappa}Q_{\Gamma,\mathsf{p}}^{\kappa(-m)}\mapsto m^{1-\kappa}P_{\Gamma,\mathsf{p}}^{1-\kappa(m)}\mapsto 0, \tag{4.5.1}$$

under the maps $I_\kappa(\Gamma)\mapsto S_{1-\kappa}(\Gamma)$ of §2.7.

We next seek to establish the utility of Proposition 4.5.2 by identifying the subspace of $I_\kappa(\Gamma)$ that is spanned by the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$.

Theorem 4.5.3. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity, and let $\kappa\in\mathbb{Z}$ with $\kappa\leq 0$. Then the set $\{Q_{\Gamma,\mathsf{p}}^{\kappa(-m)}(z)\mid \mathsf{p}\in\mathsf{P}_\Gamma, m\in\mathbb{Z}^+\}$ is a basis for the space of automorphic integrals of weight 2κ for Γ in case $\kappa<0$. When $\kappa=0$ the set $\{Q_{\Gamma,\mathsf{p}}^{(-m)}(z)\mid \mathsf{p}\in\mathsf{P}_\Gamma, m\in\mathbb{Z}^+\}$ spans a subspace of $I_0(\Gamma)$ of codimension 1.*

Proof. For $m>0$ the function $Q_{\Gamma,\mathsf{p}}^{\kappa(-m)}(z)$ has principal part $\mathrm{e}(-mz)$ at the cusp p, and vanishes at all the other cusps, so the collection $\{Q_{\Gamma,\mathsf{p}}^{\kappa(-m)}(z)\mid \mathsf{p}\in\mathsf{P}_\Gamma, m\in\mathbb{Z}^+\}$ is linearly independent. To show that it furnishes a basis we follow Niebur's proof of Theorem 3.3 in [Nie74], employing

Petersson's generalized Riemann–Roch Theorem to show that the dimension of the subspace of $I_\kappa(\Gamma)$ containing automorphic integrals with poles of degree not more than m say at p is bounded above by m less the dimension of the space $S_{1-\kappa}(\Gamma)$, for m sufficiently large. □

We write $I_0'(\Gamma)$ for the subspace of $I_0(\Gamma)$ spanned by the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{(-m)}(z)$ of weight 0 for varying $\mathsf{p} \in \mathsf{P}_\Gamma$ and $m \in \mathbb{Z}^+$.

Theorem 4.5.4. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity. Then for any $\kappa \in \mathbb{Z}$ the sequence*

$$0 \to M_\kappa(\Gamma) \to I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma) \to 0 \tag{4.5.2}$$

is exact.

Proof. The second map of (4.5.2) is an inclusion by definition, and we observed already in §2.7 that $M_\kappa(\Gamma)$ is the kernel of the associated cusp form map $I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma)$ (cf. Lemma 2.7.1), so we require to show only that the second to last map of (4.5.2) is surjective. For this we recall the fact (cf. [Iwa97]) that the holomorphic Poincaré series $P_{\Gamma,\mathsf{p}}^{1-\kappa(m)}(z)$, with varying $m \in \mathbb{Z}^+$, span the space $S_{1-\kappa}(\Gamma)$ of cusp forms of weight $2-2\kappa$ for Γ whenever $\kappa \leq 0$. Indeed, one need not vary the cusp p in order to obtain a spanning set. Given an arbitrary cusp form $g \in S_{1-\kappa}(\Gamma)$ we may then write

$$g = \sum_{n>0} a_n P_\Gamma^{1-\kappa(n)} \tag{4.5.3}$$

for some $a_n \in \mathbb{C}$, with only finitely many a_n non-zero. Employing Proposition 4.5.2 we see that the automorphic integral

$$f = \sum_{n>0} n^{2\kappa-1} a_n Q_\Gamma^{\kappa(-n)} \tag{4.5.4}$$

is mapped to g by the associated cusp form map. We conclude that the associated cusp form map is surjective. This completes the proof. □

Theorem 4.5.3 and Proposition 4.5.2 together describe the associated cusp form map $I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma)$ explicitly, and thus we obtain a powerful criterion for determining when an automorphic integral $f \in I_\kappa(\Gamma)$ lies in the subspace $M_\kappa(\Gamma)$ of modular forms. For example, we have the following corollary, indicating exactly when the modified Rademacher sum $Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z)$ is a modular form for Γ in the sense of §2.7.

Corollary 4.5.5. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the modified*

Rademacher sum $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ *is a modular form of weight* 2κ *for* Γ *if and only if the cusp form* $P^{1-\kappa(-m)}_{\Gamma,\mathsf{p}}(z)$ *vanishes identically.*

5 Structural applications

We have seen already in §4 various applications of the modified Rademacher sums, and the continuation procedure introduced in §4.1, such as the basis theorem (Theorem 4.5.3) for automorphic integrals, and the explicit description (cf. Proposition 4.5.2) of the associated cusp form map $I_\kappa(\Gamma) \to S_{1-\kappa}(\Gamma)$. In this section we explore further consequences of the modified Rademacher sum construction for the structure of the spaces of automorphic integrals associated to groups commensurable with the modular group. Applications of the modified Rademacher sums to monstrous moonshine and quantum gravity will be developed in §§6,7.

5.1 Constants

Perhaps the most striking application of the continuation procedure of §4.1 is the correction of the constant terms appearing in the classical Rademacher sums. For negative weights, the constant term in the Fourier expansion of an automorphic integral $f \in I_\kappa(\Gamma)$ is determined by the automorphy condition (2.7.13). At weight 0 constant functions are themselves automorphic integrals, so the classical Rademacher sums $R^{(m)}_{\Gamma,\mathsf{p}}(z)$ of weight 0 do not fail to be automorphic, and it is natural then to wonder about the significance of the constant term $\mathrm{c}_{\Gamma,\mathsf{p}}(m,0)$ appearing in the Fourier expansion of the modified Rademacher sum $Q^{(m)}_{\Gamma,\mathsf{p}}(z)$ of weight 0 associated to a group Γ at a cusp $\mathsf{p} \in \mathsf{P}_\Gamma$.

Let $\mathfrak{G}$ denote the set of subgroups of $G(\mathbb{Q})$ that are commensurable with $G(\mathbb{Z})$. Recall from §2.7 that for $\Gamma \in \mathfrak{G}$ we write $M_0(\Gamma)$ for the space of holomorphic functions on $\mathbb{H}$ that are invariant for the natural action of Γ and are meromorphic at the cusps of Γ. Let $\mathfrak{M}_0$ be the union of the spaces $M_0(\Gamma)$ for $\Gamma \in \mathfrak{G}$.

$$\mathfrak{M}_0 = \bigcup_{\Gamma \in \mathfrak{G}} M_0(\Gamma) \tag{5.1.1}$$

Since $\mathfrak{G}$ is closed under intersections, the set $\mathfrak{M}_0$ is in fact a subalgebra of the space $\mathcal{O}(\mathbb{H})$ of holomorphic functions on $\mathbb{H}$. Since $G(\mathbb{Q})$ is the commensurator of $G(\mathbb{Z})$, the algebra $\mathfrak{M}_0$ is $G(\mathbb{Q})$-invariant. The constant functions evidently constitute a $G(\mathbb{Q})$-invariant subspace $\mathbb{C}1 \subset \mathfrak{M}_0$. We may enquire as to the $G(\mathbb{Q})$-module structure of the quotient $\mathfrak{M}_0/\mathbb{C}1$. According to [Nor84] this quotient is irreducible, and the natural map $\mathfrak{M}_0 \to \mathfrak{M}_0/\mathbb{C}1$ admits a section.

Theorem 5.1.1 ([Nor84]). *There exists a unique* $G(\mathbb{Q})$*-submodule* $\mathfrak{M}_0' \subset \mathfrak{M}_0$ *with the property* *that the natural inclusions* $\mathbb{C}1, \mathfrak{M}_0' \subset \mathfrak{M}_0$ *induce an isomorphism*

$$\mathfrak{M}_0 \cong \mathbb{C}1 \oplus \mathfrak{M}_0' \tag{5.1.2}$$

of $G(\mathbb{Q})$*-modules.*

According to Theorem 5.1.1, for each $f \in \mathfrak{M}_0$ there is a unique $c(f) \in \mathbb{C}$ with the property that $f + c(f) \in \mathfrak{M}_0'$. The value $c(f)$ is called the *Rademacher constant of* f. The assignment $f \mapsto c(f)$ defines a linear function on $\mathfrak{M}_0$ with kernel $\mathfrak{M}_0'$ which we call the *Rademacher constant function*. We suggest that the Rademacher constant function may be generalized to automorphic integrals of weight 0 in the following way. Let $\mathfrak{I}_0$ be the union of the spaces $I_0(\Gamma)$ for $\Gamma \in \mathfrak{G}$.

$$\mathfrak{I}_0 = \bigcup_{\Gamma \in \mathfrak{G}} I_0(\Gamma) \tag{5.1.3}$$

Since $\mathfrak{G}$ is closed under intersections, the set $\mathfrak{I}_0$ is also a subalgebra of $\mathcal{O}(\mathbb{H})$, and since $G(\mathbb{Q})$ is the commensurator of $G(\mathbb{Z})$, the algebra $\mathfrak{I}_0$ is also stable under the action of $G(\mathbb{Q})$. The constant functions again constitute a $G(\mathbb{Q})$-invariant subspace $\mathbb{C}1 \subset \mathfrak{I}_0$. We conjecture that the natural analogue of Theorem 5.1.1 holds for $\mathfrak{I}_0$. Precisely, we conjecture that there is a unique $G(\mathbb{Q})$-submodule $\mathfrak{I}_0' \subset \mathfrak{I}_0$ with the property that the natural inclusions induce an isomorphism

$$\mathfrak{I}_0 \cong \mathbb{C}1 \oplus \mathfrak{I}_0' \tag{5.1.4}$$

of $G(\mathbb{Q})$-modules. Further, we conjecture that $\mathfrak{I}_0'$ is just the space spanned by the modified Rademacher sums $Q_{\Gamma,\mathsf{p}}^{\kappa(-m)}(z)$ for $\Gamma \in \mathfrak{G}$ and $\mathsf{p} \in \mathsf{P}_\Gamma$ and $m \in \mathbb{Z}^+$.

5.2 Inner products

Let Γ be a group commensurable with $G(\mathbb{Z})$ and let $\kappa \in \mathbb{Z}^+$. Then the space $S_\kappa(\Gamma)$ of cusp forms of weight 2κ for Γ becomes a Hilbert space when equipped with the *Petersson inner product*, defined by setting

$$\langle f, g \rangle = \int_{\mathfrak{F}_\Gamma} f(z)\overline{g(z)}\Im(z)^{2\kappa} \mathrm{d}\mu(z) \tag{5.2.1}$$

for $f, g \in S_\kappa(\Gamma)$, where $\mathfrak{F}_\Gamma$ is a fundamental domain for Γ. Let us define a *normalized Petersson inner product of weight* 2κ *for* Γ, to be denoted $\langle \cdot\,, \cdot \rangle_\Gamma^\kappa$, by setting

$$\langle f, g \rangle_\Gamma^\kappa = (4\pi)^{(2\kappa-2)} \int_{\mathfrak{F}_\Gamma} f(z)\overline{g(z)}\Im(z)^{2\kappa} \mathrm{d}\mu(z) \tag{5.2.2}$$

for $f,g\in S_\kappa(\Gamma)$. It is well known (and follows from Theorem 3.4.3), that for $\kappa,m\in\mathbb{Z}^+$ and p a cusp for Γ, the holomorphic Poincaré series $P^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ is a cusp form of weight 2κ for Γ in case Γ has width one at infinity. A standard calculation (cf. [Iwa97]) shows that we have

$$\left\langle P^{\kappa(m)}_{\Gamma,\mathsf{p}},P^{\kappa(n)}_{\Gamma,\mathsf{q}}\right\rangle^{\kappa}_{\Gamma}=n^{2-2\kappa}(\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\delta_{m,n}+\mathrm{c}^{\kappa}_{\Gamma,\mathsf{p}|\mathsf{q}}(m,n))\tag{5.2.3}$$

for $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ and $m,n\in\mathbb{Z}^+$. According to Theorem 3.4.3 the right hand side of (5.2.3) is, up to the scalar factor $n^{2-2\kappa}$, the coefficient of $\mathrm{e}(nz)$ in the expansion $P^{\kappa(m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ of the Poincaré series $P^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ at q. Now the modified Rademacher sums $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$, for $-\kappa,-m\in\mathbb{Z}^+$, span the space $I_\kappa(\Gamma)$ of automorphic integrals for weight 2κ for Γ, according to Theorem 4.5.3, and thus serve an analogous rôle for the spaces $I_\kappa(\Gamma)$ as the Poincaré series $P^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ do for the spaces $S_\kappa(\Gamma)$. It is natural then to use the right hand side of (5.2.3) to extend the normalized Petersson inner product to negative weights. In light of the fact, established in Proposition 4.4.8, that the coefficient of $\mathrm{e}(-nz)$ in the expansion $Q^{\kappa(-m)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ of the modified Rademacher sum $Q^{\kappa(-m)}_{\Gamma,\mathsf{p}}(z)$ at q is $\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\delta_{m,n}$ for $m,n\in\mathbb{Z}^+$, we define an inner product $\langle\cdot\,,\cdot\rangle^{\kappa}_{\Gamma}$ on $I_\kappa(\Gamma)$ by setting

$$\left\langle Q^{\kappa(-m)}_{\Gamma,\mathsf{p}},Q^{\kappa(-n)}_{\Gamma,\mathsf{q}}\right\rangle^{\kappa}_{\Gamma}=n^{2-2\kappa}\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\delta_{m,n}\tag{5.2.4}$$

for $\mathsf{p},\mathsf{q}\in\mathsf{P}_\Gamma$ and $m,n\in\mathbb{Z}^+$, when $\kappa<0$. In case $\kappa=0$ the modified Rademacher sums $Q^{\kappa(-m)}_{\Gamma,\mathsf{p}}(z)$ span a subspace $I_0'(\Gamma)$ of $I_0(\Gamma)$ of codimension 1 (cf. Theorem 4.5.3 and §5.1) and we may use the formula (5.2.4) to define an inner product on this subspace $I_0'(\Gamma)$.

$$\left\langle Q^{(-m)}_{\Gamma,\mathsf{p}},Q^{(-n)}_{\Gamma,\mathsf{q}}\right\rangle^{0}_{\Gamma}=n^{2}\delta_{\Gamma,\mathsf{p}|\mathsf{q}}\delta_{m,n}\tag{5.2.5}$$

A complement to $I_0'(\Gamma)$ in $I_0(\Gamma)$ is spanned by the constant functions. We extend the inner product $\langle\cdot\,,\cdot\rangle^{0}_{\Gamma}$ to all of $I_0(\Gamma)$ by adopting the convention that

$$\left\langle Q^{(-m)}_{\Gamma,\mathsf{p}},f\right\rangle^{0}_{\Gamma}=0\tag{5.2.6}$$

for all $\mathsf{p}\in\mathsf{P}_\Gamma$ and $m\in\mathbb{Z}^+$ whenever f is identically constant.

5.3 Branching

Let Δ and Γ be groups commensurable with $G(\mathbb{Z})$ and suppose that Δ is a subgroup of Γ. Then an automorphic integral for Γ is also an automorphic integral for Δ. By Theorem 4.5.3 the modified Rademacher sums span the spaces of automorphic integrals, so it is natural to consider the problem of expressing the modified Rademacher sums $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}$ associated to Γ in terms of the modified Rademacher sums $Q^{\kappa(n)}_{\Delta,\mathsf{r}}$ associated to Δ.

Suppose then that Δ and Γ are groups commensurable with $G(\mathbb{Z})$ and Δ is a subgroup of

Γ. Let p be a cusp for Γ, let Σ_{p} be a scaling coset for Γ at p, and choose a system $\{\Sigma_{\mathsf{r}} \mid \mathsf{r} \in \mathsf{P}_\Delta\}$ of scaling cosets for Δ. Suppose for now that κ is a negative integer. Then by Theorem 4.5.3 we have

$$Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z) = \sum_{\mathsf{r}\in\mathsf{P}_\Delta} b^n_{\mathsf{r}} Q^{\kappa(n)}_{\Delta,\mathsf{r}}(z) \tag{5.3.1}$$

for some $b^n_{\mathsf{r}} \in \mathbb{C}$, and these b^n_{r} are non-zero for only finitely many $n < 0$. Furthermore, since the modified Rademacher sum $Q^{\kappa(m)}_{\Gamma,\mathsf{p}}(z)$ has no poles away from p, the coefficient b^n_{r} can be non-zero only when r lies in the preimage of p under the natural map $\mathsf{X}_\Delta \to \mathsf{X}_\Gamma$, which is to say, b^n_{r} is non-zero only when $\mathsf{r} \in \Delta\backslash\mathsf{p}$. It is natural then to consider the map

$$\begin{aligned} \Delta\backslash\Sigma_{\mathsf{p}} &\to \Delta\backslash\mathsf{p} \\ \Delta\sigma &\mapsto \Delta\sigma\cdot\infty \end{aligned} \tag{5.3.2}$$

sending right cosets of Δ in Σ_{p} to cusps of Δ contained in $\mathsf{p} \subset \hat{\mathbb{Q}}$. The map (5.3.2) is always surjective. We may ask under what circumstances it is also injective.

Lemma 5.3.1. *Let Δ and Γ be groups commensurable with $G(\mathbb{Z})$ and suppose that Δ is a subgroup of Γ. Let p be a cusp for Γ and let Σ_{p} be a scaling coset for Γ at p. Then the map $\Delta\backslash\Sigma_{\mathsf{p}} \to \Delta\backslash\mathsf{p}$ of (5.3.2) is injective if and only if $\Delta\sigma$ is a scaling coset for Δ at $\Delta\sigma\cdot\infty$ for every $\Delta\sigma \in \Delta\backslash\Sigma_{\mathsf{p}}$.*

Proof. Suppose the map $\Delta\backslash\Sigma_{\mathsf{p}} \to \Delta\backslash\mathsf{p}$ of (5.3.2) is injective, and let $\sigma \in \Sigma_{\mathsf{p}}$. The forward implication of the lemma follows if we can show that $\Delta\sigma$ is a scaling coset for Δ at $\Delta\sigma\cdot\infty$. For this it suffices to show that $(\sigma^{-1}\Delta\sigma)_\infty = B(\mathbb{Z})$. Since $\sigma^{-1}\Delta\sigma$ is a subgroup of $\sigma^{-1}\Gamma\sigma$, and $(\sigma^{-1}\Gamma\sigma)_\infty = (\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}})_\infty = B(\mathbb{Z})$ by the defining properties of Σ_{p}, we have the inclusion $(\sigma^{-1}\Delta\sigma)_\infty \subset B(\mathbb{Z})$, so it suffices to show that the translation T belongs to $\sigma^{-1}\Delta\sigma$. Now $\Delta\sigma T$ is also a coset of Δ in Σ_{p}, since $\Gamma\sigma = \Sigma_{\mathsf{p}}$ is a union of left cosets of $B(\mathbb{Z})$. Since T fixes ∞ we have $\Delta\sigma T\cdot\infty = \Delta\sigma\cdot\infty$, and thus the cosets $\Delta\sigma T$ and $\Delta\sigma$ coincide by the assumed injectivity of the map (5.3.2). It follows that $T \in \sigma^{-1}\Delta\sigma$, so that $\Delta\sigma$ is indeed a scaling coset for Δ.

For the reverse implication suppose that $\Delta\sigma$ is a scaling coset for Δ for every $\sigma \in \Sigma_{\mathsf{p}}$. Let $\sigma, \sigma' \in \Sigma_{\mathsf{p}}$ and suppose that $\Delta\sigma\cdot\infty = \Delta\sigma'\cdot\infty$. Then $\sigma^{-1}\delta\sigma' \in (\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}})_\infty = B(\mathbb{Z})$ for some $\delta \in \Delta$, so $\sigma^{-1}\delta\sigma' = T^n$ for some $n \in \mathbb{Z}$, and this implies $\Delta\sigma' = \Delta\sigma T^n$. Now the assumption that $\Delta\sigma$ is a scaling coset for Δ implies that $\Delta\sigma$ is a union of left cosets of $B(\mathbb{Z})$, so $\Delta\sigma T^n = \Delta\sigma$. We conclude that $\Delta\sigma' = \Delta\sigma$, so that the map $\Delta\backslash\Sigma_{\mathsf{p}} \to \Delta\backslash\mathsf{p}$ is indeed injective. This completes the proof of the lemma. ☐

According to the discussion of §2.6 a coset $\Delta\sigma \in \Delta\backslash\Sigma_{\mathsf{p}}$ becomes a scaling coset for Δ at $\Delta\sigma\cdot\infty$ only once we multiply it on the right by $[\beta]$ (cf. (2.3.3)) for some $\beta \in \mathbb{Q}^+$. In fact, this β is a positive integer, for we have $(\sigma^{-1}\Delta\sigma)_\infty \subset (\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}})_\infty = B(\mathbb{Z})$, so that $(\sigma^{-1}\Delta\sigma)_\infty$ is generated by T^n for some $n \in \mathbb{Z}^+$. In order that $\Delta\sigma[\beta]$ be a scaling coset for Δ at $\Delta\sigma \cdot \infty$ we should have $([1/\beta]\sigma^{-1}\Delta\sigma[\beta])_\infty = B(\mathbb{Z})$, so the computation $[1/\beta]T^n[\beta] = T^{n/\beta}$ shows that $\beta = n$. Evidently we may define a function $\Delta\backslash\Sigma_{\mathsf{p}} \to \mathbb{Z}^+$ by mapping the coset $\Delta\sigma$ to the positive integer n such that T^n generates $(\sigma^{-1}\Delta\sigma)_\infty$. We next show that this function $\Delta\backslash\Sigma_{\mathsf{p}} \to \mathbb{Z}^+$ factors through the map $\Delta\backslash\Sigma_{\mathsf{p}} \to \Delta\backslash\mathsf{p}$ of (5.3.2).

Lemma 5.3.2. *Let Δ and Γ be groups commensurable with $G(\mathbb{Z})$, and suppose that Δ is a subgroup of Γ. Let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ and let Σ_{p} be a scaling coset for Γ at p. Then for any $\sigma_1, \sigma_2 \in \Sigma_{\mathsf{p}}$ the identity $\Delta\sigma_1 \cdot \infty = \Delta\sigma_2 \cdot \infty$ implies $(\sigma_1^{-1}\Delta\sigma_1)_\infty = (\sigma_2^{-1}\Delta\sigma_2)_\infty$.*

Proof. Set $\mathsf{r} = \Delta\sigma_1 \cdot \infty = \Delta\sigma_2 \cdot \infty$. Since $(\sigma^{-1}\Gamma\sigma)_\infty = (\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}})_\infty = B(\mathbb{Z})$ for any $\sigma \in \Sigma_{\mathsf{p}}$ the groups $(\sigma_1^{-1}\Delta\sigma_1)_\infty$ and $(\sigma_2^{-1}\Delta\sigma_2)_\infty$ are both contained in $B(\mathbb{Z})$. Let n_1 and n_2 be the positive integers such that $(\sigma_1^{-1}\Delta\sigma_1)_\infty$ is generated by T^{n_1} and $(\sigma_2^{-1}\Delta\sigma_2)_\infty$ is generated by T^{n_2}. Then $\Delta\sigma_1[n_1]$ and $\Delta\sigma_2[n_2]$ are both scaling cosets for Δ at r, so $\Delta\sigma_1[n_1] = \Delta\sigma_2[n_2]T^\alpha$ for some $\alpha \in \mathbb{Q}$. This implies that $[n_2]T^\alpha[1/n_1]$ is an element of $(\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}})_\infty = B(\mathbb{Z})$, so that $[n_2]T^\alpha[1/n_1] = T^k$ for some $k \in \mathbb{Z}$. Now we compute

$$[n_2]T^\alpha[1/n_1] = \begin{bmatrix} n_2 & 0 \\ 0 & 1 \end{bmatrix}\begin{bmatrix} 1 & \alpha \\ 0 & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 0 & n_1 \end{bmatrix} = \begin{bmatrix} n_2 & n_2\alpha n_1 \\ 0 & n_1 \end{bmatrix} = \begin{bmatrix} 1 & k \\ 0 & 1 \end{bmatrix} \tag{5.3.3}$$

and conclude that $n_1 = n_2$, as we required to show. □

On the basis of Lemma 5.3.2 we may define a function $\Delta\backslash\mathsf{p} \to \mathbb{Z}^+$ for each cusp p of Γ by first choosing a scaling coset Σ_{p} for Γ at p, and then sending the cusp $\mathsf{r} \in \Delta\backslash\mathsf{p}$ of Δ to the unique positive integer n satisfying $(\sigma^{-1}\Delta\sigma)_\infty = \langle T^n \rangle$ when $\mathsf{r} = \Delta\sigma \cdot \infty$. Observe now that this map does not depend upon the choice of scaling coset Σ_{p}, for if we replace $\sigma \in \Sigma_{\mathsf{p}}$ with $\sigma' = \sigma T^\alpha \in \Sigma_{\mathsf{p}}T^\alpha$ for some $\alpha \in \mathbb{Q}$, then we have

$$((\sigma')^{-1}\Delta\sigma')_\infty = (T^{-\alpha}\sigma^{-1}\Delta\sigma T^\alpha)_\infty = T^{-\alpha}(\sigma^{-1}\Delta\sigma)_\infty T^\alpha = (\sigma^{-1}\Delta\sigma)_\infty. \tag{5.3.4}$$

In light of this we may define a map $w_\Gamma : \mathsf{P}_\Delta \to \mathbb{Z}^+$, which we call the *width function associated to* Γ, by setting $w_\Gamma(\mathsf{r}) = n$ in case $\mathsf{r} = \Delta\sigma \cdot \infty$ and T^n generates $(\sigma^{-1}\Delta\sigma)_\infty$ and $\Gamma\sigma$ is a scaling coset for Γ at the unique cusp of Γ containing r.

$$\begin{gathered} w_\Gamma : \mathsf{P}_\Delta \to \mathbb{Z}^+ \\ \mathsf{r} = \Delta\sigma \cdot \infty,\, \Gamma\sigma \in \mathfrak{S}_{\Gamma\mathsf{r}} \Longrightarrow (\sigma^{-1}\Delta\sigma)_\infty = \langle T^{w_\Gamma(\mathsf{r})} \rangle \end{gathered} \tag{5.3.5}$$

We call $w_\Gamma(\mathsf{r})$ the *width of* r *with respect to* Γ. The next result gives upper bounds for the width functions.

Lemma 5.3.3. *Let* Δ *and* Γ *be groups commensurable with* $G(\mathbb{Z})$*, and suppose that* Δ *is a subgroup of* Γ*. Then we have*

$$\sum_{\mathsf{r}\in\Delta\backslash\mathsf{p}} w_\Gamma(\mathsf{r}) = \#\Delta\backslash\Gamma \tag{5.3.6}$$

for every cusp p *of* Γ*.*

Proof. Let p be a cusp of Γ and choose a scaling coset Σ_p for Γ at p, and let us temporarily write c_p for the map $\Delta\sigma \mapsto \Delta\sigma\cdot\infty$ of (5.3.2). We claim that $w_\Gamma(\mathsf{r})$ is the cardinality of the preimage of r under c_p, for each $\mathsf{r}\in\Delta\backslash\mathsf{p}$. The identity (5.3.6) follows from this because the cardinality $\#\Delta\backslash\Sigma_\mathsf{p}$ of the source of c_p is just the number of cosets of Δ in Γ. To compute $\#c_\mathsf{p}^{-1}(\mathsf{r})$ suppose $\Delta\sigma\cdot\infty = \Delta\sigma'\cdot\infty$ for some $\sigma,\sigma'\in\Sigma_\mathsf{p}$. Then $\sigma^{-1}\delta\sigma' \in (\Sigma_\mathsf{p}^{-1}\Sigma_\mathsf{p})_\infty = B(\mathbb{Z})$ for some $\delta\in\Delta$, so that $\Delta\sigma' = \Delta\sigma T^k$ for some $k\in\mathbb{Z}$. Now $\Delta\sigma T$ is an element of $\Delta\backslash\Sigma_\mathsf{p}$ whenever $\Delta\sigma$ is, for Σ_p is a union of left cosets of $B(\mathbb{Z})$ by construction. So we have $c_\mathsf{p}^{-1}(\mathsf{r}) = \{\Delta\sigma T^k \mid k\in\mathbb{Z}\}$ for any $\sigma\in\Sigma_\mathsf{p}$ satisfying $\mathsf{r} = \Delta\sigma\cdot\infty$. If $w_\Gamma(\mathsf{r}) = n$, so that $(\sigma^{-1}\Delta\sigma)_\infty = \langle T^n\rangle$ then $\Delta\sigma T^k = \Delta\sigma T^l$ if and only if $n|(k-l)$. This establishes the claim that $\#c_\mathsf{p}^{-1}(\mathsf{r}) = w_\Gamma(\mathsf{r})$, and completes the proof. □

We can now compute the coefficients b_r^n in (5.3.1) explicitly, and thus obtain a branching theorem for the modified Rademacher sums. Even though we formulated the expression (5.3.1) under the assumption that κ be negative, our methods will apply for all $\kappa\in\mathbb{Z}$ such that $\kappa\le 0$.

Theorem 5.3.4. *Let* Δ *and* Γ *be groups commensurable with* $G(\mathbb{Z})$*. Suppose that* Δ *is a subgroup of* Γ*, and suppose that* Δ *and* Γ *both have width one at infinity. Let* p *be a cusp of* Γ *and let* Σ_p *be a scaling coset for* Γ *at* p*. Let* $\kappa, m\in\mathbb{Z}$ *such that* $\kappa\le 0$ *and* $m<0$*. Then there exists a system of scaling cosets* $\{\Sigma_\mathsf{r}\mid \mathsf{r}\in\mathsf{P}_\Delta\}$ *for* Δ *for which we have*

$$Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z) = \sum_{\mathsf{r}\in\Delta\backslash\mathsf{p}} w_\Gamma(\mathsf{r}) Q_{\Delta,\mathsf{r}}^{\kappa(mw_\Gamma(\mathsf{r}))}(z). \tag{5.3.7}$$

Proof. Let Δ and Γ be as in the statement of the lemma. Under the assumption that Γ has width one at infinity, and the convention that $\Sigma_{\Gamma\cdot\infty} = \Gamma$ in this case (cf. §2.6), we have

$$Q_{\Gamma,\mathsf{p}}^{\kappa(m)}(z) = Q_{[\![\Sigma_\mathsf{p}^{-1}}^{\kappa(m)}(z) = \sum_{\Delta\sigma\in\Delta\backslash\Sigma_\mathsf{p}} Q_{[\![\sigma^{-1}\Delta}^{\kappa(m)}(z), \tag{5.3.8}$$

and we may attempt to write each summand $Q_{[\![\sigma^{-1}\Delta}^{\kappa(m)}(z)$ in terms of the modified Rademacher sums $Q_{\Delta,\mathsf{r}}^{\kappa(n)}(z)$ associated to Δ. Let $\Delta\sigma\in\Delta\backslash\Sigma_\mathsf{p}$ and set $\mathsf{r} = \Delta\sigma\cdot\infty$. Supposing that $w_\Gamma(\mathsf{r}) = n$, so that $(\sigma^{-1}\Delta\sigma)_\infty = \langle T^n\rangle$, we set $\Sigma_{\mathsf{r}} = \Delta\sigma[n]$. Then we have

$$Q^{\kappa(m)}_{[\![\sigma^{-1}\Delta}(z) = Q^{\kappa(m)}_{[\![[n][1/n]\sigma^{-1}\Delta}(z) = Q^{\kappa(mn)}_{[\![\Sigma_{\mathsf{r}}^{-1}}(z), \tag{5.3.9}$$

since $Q^{\kappa(m)}_{[\![[n]\chi}(z,s) = Q^{\kappa(mn)}_{[\![\chi}(z,s)$ (cf. §4.1). Under the assumption that Δ has width one at infinity, so that $\Sigma_{\Delta\cdot\infty} = \Delta$, we may rewrite the right most term in (5.3.9) as $Q^{\kappa(mn)}_{\Delta,\mathsf{r}}(z)$. We see then that a coset $\Delta\sigma$ of Δ in Σ_{p} contributes a term $Q^{\kappa(mw_\Gamma(\mathsf{r}))}_{\Delta,\mathsf{r}}(z)$ to the right hand side of (5.3.7), where $\mathsf{r} = \Delta\sigma\cdot\infty$. According to the proof of Lemma 5.3.3 there are exactly $w_\Gamma(\mathsf{r})$ cosets $\Delta\sigma$ in $\Delta\backslash\Sigma_{\mathsf{p}}$ satisfying $\mathsf{r} = \Delta\sigma\cdot\infty$. The required identity (5.3.7) now follows. □

From the proof of Theorem 5.3.4 we see that the existence of the scaling cosets of the conclusion is verified constructively: if $\mathsf{r} = \Delta\sigma\cdot\infty$ for some coset $\Delta\sigma \in \Delta\backslash\Sigma_{\mathsf{p}}$, then we may take $\Sigma_{\mathsf{r}} = \Delta\sigma[w_\Gamma(\mathsf{r})]$.

By utilizing the inner products $\langle\cdot\,,\cdot\rangle^\kappa_\Delta$ of §5.2 we can reformulate Theorem 5.3.4 in a way that is independent of scaling coset choices.

Theorem 5.3.5. *Let Δ and Γ be groups commensurable with $G(\mathbb{Z})$. Suppose that Δ is a subgroup of Γ, and suppose that Δ and Γ both have width one at infinity. Let p be a cusp of Γ, let κ min$\mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then we have*

$$\left|\left\langle Q^{\kappa(m)}_{\Gamma,\mathsf{p}}, Q^{\kappa(n)}_{\Delta,\mathsf{r}}\right\rangle^\kappa_\Delta\right|^2 = w_\Gamma(\mathsf{r})\delta_{\Gamma,\mathsf{p}|\Gamma\mathsf{r}}\delta_{mw_\Gamma(\mathsf{r}),n} \tag{5.3.10}$$

for all $\mathsf{r} \in \mathsf{P}_\Delta$ and $n < 0$, for any choice of scaling coset systems for Δ and Γ.

To conclude this section we comment on the branching of Rademacher sums in the case that Γ both contains and normalizes Δ. Suppose then that Δ and Γ have width one at infinity, and consider the case that p is the infinite cusp $\Gamma\cdot\infty$ in (5.3.2). Then we are speaking of the map

$$\begin{aligned} \Delta\backslash\Gamma &\to \Delta\backslash\Gamma\cdot\infty \\ \Delta\gamma &\mapsto \Delta\gamma\cdot\infty, \end{aligned} \tag{5.3.11}$$

and this map is injective (and thus bijective) when Γ normalizes Δ. Indeed, since Δ is supposed to have width one at infinity we have $(\gamma^{-1}\Delta\gamma)_\infty = \Delta_\infty = B(\mathbb{Z})$, so that every coset $\Delta\gamma \in \Delta\backslash\Gamma$ is indeed a scaling coset for Δ at $\mathsf{r} = \Delta\gamma\cdot\infty$, and the injectivity of (5.3.11) follows from Lemma 5.3.1. Applying Theorem 5.3.4 now with $\mathsf{p} = \Gamma\cdot\infty$ we obtain the following result.

Proposition 5.3.6. *Suppose that Δ and Γ are groups commensurable with $G(\mathbb{Z})$ that both have width one at infinity, and suppose that Γ contains and normalizes Δ. Let $\kappa, m \in \mathbb{Z}$ such that*

$\kappa \leq 0$ and $m < 0$. Then we have

$$Q_{\Gamma}^{\kappa(m)}(z) = \sum_{\mathsf{r} \in \Delta \backslash \mathsf{p}} Q_{\Delta,\mathsf{r}}^{\kappa(m)}(z) \tag{5.3.12}$$

when the scaling cosets for Δ at the cusps $\mathsf{r} \in \Delta \backslash \Gamma \cdot \infty$ are taken to lie in $\Delta \backslash \Gamma$.

Theorem 5.3.5 now implies the following reformulation of Proposition 5.3.6 which is independent of scaling coset choices.

Proposition 5.3.7. *Suppose that Δ and Γ are groups commensurable with $G(\mathbb{Z})$ that both have width one at infinity, and suppose that Γ contains and normalizes Δ. Then we have*

$$\left| \left\langle Q_{\Gamma}^{\kappa(-1)}, Q_{\Delta,\mathsf{r}}^{\kappa(-1)} \right\rangle_{\Delta}^{\kappa} \right|^2 = \delta_{\Gamma,\mathsf{p}|\Gamma\mathsf{r}} \tag{5.3.13}$$

for all $\mathsf{r} \in \mathsf{P}_{\Delta}$, for any choice of scaling coset system for Δ.

5.4 Fractional orders

Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\phi, \psi \in G(\mathbb{Q})$ and set $U = [\![\phi^{-1}\Gamma\psi$. Let us consider the problem of writing the modified Rademacher sum $Q_U^{\kappa(m)}(z)$ in terms of Rademacher sums of the form $Q_{\Gamma',\mathsf{p}'}^{\kappa(m')}(z)$ for some group Γ' and some cusp $\mathsf{p}' \in \mathsf{P}_{\Gamma'}$. According to §4.1 we have $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m)}(z) = Q_{\Gamma',\mathsf{p}'}^{\kappa(m)}(z)$ for $\Gamma' = \Gamma^{\mathsf{q}}$ and $\mathsf{p}' = \mathsf{p}^{\mathsf{q}}$ (cf. (4.1.9)), so we are done if we can write $Q_U^{\kappa(m)}(z)$ in terms of $Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(n)}(z)$ for some cusps $\mathsf{p}, \mathsf{q} \in \mathsf{P}_{\Gamma}$ for Γ. Set $\mathsf{p} = \Gamma\phi \cdot \infty$ and $\mathsf{q} = \Gamma\psi \cdot \infty$. By the discussion of §2.6 there exist unique $\mu, \nu \in \mathbb{Q}^+$ such that the cosets $\Sigma_{\mathsf{p}} = \Gamma\phi[\mu]$ and $\Sigma_{\mathsf{q}} = \Gamma\psi[\nu]$ (cf. (2.3.3)) are scaling cosets for Γ at p and q, respectively. We then have $U = [\![[\mu]\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}[1/\nu]$. Let $\chi \in \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{q}}$ and consider the contribution $Q_{[\![[\mu]\chi[1/\nu]}^{\kappa(m)}(z,s)$ of the coset $[\![[\mu]\chi[1/\nu] \in U$ to the modified continued Rademacher sum $Q_U^{\kappa(m)}(z,s)$. As the following lemma demonstrates, the factor $[1/\nu]$ induces a re-scaling of the input variable z.

Lemma 5.4.1. *Let $\chi \in G(\mathbb{Q})$ and let $\nu \in \mathbb{Q}^+$. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then we have*

$$Q_{[\![\chi[1/\nu]}^{\kappa(m)}(z,s) = \frac{1}{\nu^{\kappa}} Q_{[\![\chi}^{\kappa(m)}\left(\frac{z}{\nu}, s\right). \tag{5.4.1}$$

Proof. We recall from (4.1.4) that the modified continued Rademacher component function $Q_{[\![\chi[1/\nu]}^{\kappa(m)}(z,s)$ is, by definition, the difference $T_{[\![\chi[1/\nu]}^{\kappa(m)}(z,s) - T_{0,[\![\chi[1/\nu]}^{\kappa(m)}(s)$, where the functions $T_{[\![\chi[1/\nu]}^{\kappa(m)}(z,s)$ and $T_{0,[\![\chi[1/\nu]}^{\kappa(m)}(s)$ are defined by (4.1.1) and (4.1.3), respectively. We compute $\operatorname{jac}([\![\chi[1/\nu]\,, z) = \operatorname{jac}([\![\chi\,, z/\nu)/\nu$, and use the fact that $[1/\nu]$ fixes both ∞ and 0 to verify that

$$T_{[\![\chi[1/\nu]}^{\kappa(m)}(z,s) = \frac{1}{\nu^{\kappa}} T_{[\![\chi}^{\kappa(m)}\left(\frac{z}{\nu}, s\right), \quad T_{0,[\![\chi[1/\nu]}^{\kappa(m)}(s) = \frac{1}{\nu^{\kappa}} T_{0,[\![\chi}^{\kappa(m)}(s). \tag{5.4.2}$$

The claim follows from these identities. □

We now seek to describe the effect of the factor $[\mu]$ in $Q^{\kappa(m)}_{[\![\mu]\chi}(z,s)$, for arbitrary $\chi \in G(\mathbb{Q})$. Inspecting (4.1.1) we find that

$$T^{\kappa(m)}_{[\![\mu]\chi}(z,s) = \mu^{\kappa}\,\mathrm{e}(m\mu\chi\cdot z)\,\mathrm{t}^{\kappa}(m\mu,\chi,z,s)\,\mathrm{jac}(\chi,z)^{\kappa}, \tag{5.4.3}$$

which suggests that we generalize the notion of Rademacher sum so as to allow for fractional orders. Recall from (2.3.5) that $B(\alpha\mathbb{Z})$ denotes the subgroup of $B_u(\mathbb{Q})$ generated by T^{α} (cf. (2.3.4)). For general $\mu \in \mathbb{Q}^+$ the right hand side of (5.4.3) will not be invariant under the replacement of χ by $T\chi$, so a Rademacher sum of fractional order is not naturally defined by collections of cosets of $B(\mathbb{Z})$, but rather, by cosets of $B(h\mathbb{Z})$ for a suitably chosen positive integer $h \in \mathbb{Z}^+$.

Given $h \in \mathbb{Z}^+$ and $\chi \in G(\mathbb{Q})$ let us write $\llbracket^h\chi$ as a shorthand for $B(h\mathbb{Z})\chi$, and for $X \subset G(\mathbb{Q})$ let us write $\llbracket^h X$ as a shorthand for the set of right cosets of $B(h\mathbb{Z})$ determined by elements of X, so that

$$\llbracket^h X = \{B(h\mathbb{Z})\chi \mid \chi \in X\}\,. \tag{5.4.4}$$

Let $\kappa \in \mathbb{Z}$ such that $\kappa \leq 0$. We define modified and normalized fractional Rademacher sums as follows, in analogy with the constructions of §4.1. For $\mu = -g/h$ with $(g,h) = 1$ and $g,h \in \mathbb{Z}^+$, and for $\llbracket^h\chi \in \llbracket^h G(\mathbb{Q})$, we define the *continued fractional Rademacher component function of weight* 2κ *and order* μ *associated to* $\llbracket^h\chi$, denoted $(z,s) \mapsto T^{\kappa(\mu)}_{\llbracket^h\chi}(z,s)$, by setting

$$T^{\kappa(\mu)}_{\llbracket^h\chi}(z,s) = \mathrm{e}(\mu\llbracket^h\chi\cdot z)\,\mathrm{t}^{\kappa}(\mu,\llbracket^h\chi,z,s)\,\mathrm{jac}(\llbracket^h\chi,z)^{\kappa}, \tag{5.4.5}$$

where $\mathrm{jac}(\llbracket^h\chi,z) = \mathrm{jac}(\chi,z)$, and $\mathrm{t}^{\kappa}(\mu,\llbracket^h\chi,z,s)$ is the *continued fractional Rademacher regularization factor of weight* 2κ, which is in turn given by

$$\mathrm{t}^{\kappa}(\mu,\llbracket^h\chi,z,s) = \Phi(s-2\kappa,1+s-2\kappa,\mu\llbracket^h\chi\cdot\infty-\mu\llbracket^h\chi\cdot z)(2\pi\mathbf{i}(\mu\llbracket^h\chi\cdot z-\mu\llbracket^h\chi\cdot\infty))^{s-2\kappa} \tag{5.4.6}$$

in case $\llbracket^h\chi \in \llbracket^h G(\mathbb{Q})^{\times}$, and $\mathrm{t}^{\kappa}(\mu,\llbracket^h\chi,z,s) = 1$ otherwise. We define a function $s \mapsto T^{\kappa(\mu)}_{0,\llbracket^h\chi}(s)$ by setting

$$\begin{aligned} T^{\kappa(\mu)}_{0,\llbracket^h\chi}(s) = {} & \mathrm{e}(\mu\llbracket^h\chi\cdot\infty)\left(2\pi\mathbf{i}(\mu\llbracket^h\chi\cdot 0-\mu\llbracket^h\chi\cdot\infty)\right)^{(s-2\kappa)}\mathrm{jac}(\llbracket^h\chi,0)^{\kappa} \\ & -\mathrm{e}(s/2)\,\mathrm{e}(\mu\llbracket^h\chi\cdot\infty)\left(2\pi\mathbf{i}(\mu\llbracket^h\chi\cdot\infty-\mu\llbracket^h\chi\cdot 0)\right)^{(s-2\kappa)}\mathrm{jac}(\llbracket^h\chi,0)^{\kappa} \end{aligned} \tag{5.4.7}$$

in case $\llbracket^h\chi \in \llbracket G(\mathbb{Q})^{\times\times}$, and by setting $T^{\kappa(\mu)}_{0,\llbracket^h\chi}(s) = 0$ otherwise, and we define the *modified* *continued fractional Rademacher component function of weight* 2κ *and order* μ *associated to* $\llbracket^h\chi$, denoted $(z,s)\mapsto Q^{\kappa(\mu)}_{\llbracket^h\chi}(z,s)$, by subtracting $T^{\kappa(\mu)}_{0,\llbracket^h\chi}(z,s)$ from $T^{\kappa(\mu)}_{\llbracket^h\chi}(z,s)$.

$$Q^{\kappa(\mu)}_{\llbracket^h\chi}(z,s)=T^{\kappa(\mu)}_{\llbracket^h\chi}(z,s)-T^{\kappa(\mu)}_{0,\llbracket^h\chi}(z,s) \tag{5.4.8}$$

For $U\subset\llbracket^hG(\mathbb{Q})$ we now define the *continued fractional Rademacher sum of weight* 2κ *and order* μ *associated to* U, denoted $T^{\kappa(\mu)}_U(z,s)$, and the *modified continued fractional Rademacher sum of weight* 2κ *and order* μ *associated to* U, denoted $Q^{\kappa(\mu)}_U(z,s)$, by setting

$$T^{\kappa(\mu)}_U(z,s)=\sum_{\llbracket^h\chi\in U}T^{\kappa(\mu)}_{\llbracket^h\chi}(z,s), \tag{5.4.9}$$

$$Q^{\kappa(\mu)}_U(z,s)=\sum_{\llbracket^h\chi\in U}Q^{\kappa(\mu)}_{\llbracket^h\chi}(z,s), \tag{5.4.10}$$

when these sums are absolutely locally uniformly convergent, and given such circumstances we define $T^{\kappa(\mu)}_U(z)$ and $Q^{\kappa(\mu)}_U(z)$ by taking the limit as s tends to 1 in $T^{\kappa(\mu)}_U(z,s)$ and $Q^{\kappa(\mu)}_U(z,s)$, respectively, so long as these limits exist.

$$T^{\kappa(\mu)}_U(z)=\lim_{s\to1^+}T^{\kappa(\mu)}_U(z,s) \tag{5.4.11}$$

$$Q^{\kappa(\mu)}_U(z)=\lim_{s\to1^+}Q^{\kappa(\mu)}_U(z,s) \tag{5.4.12}$$

We call $T^{\kappa(\mu)}_U(z)$ the *normalized fractional Rademacher sum of weight* 2κ *and order* μ *associated to* U, and we call $Q^{\kappa(\mu)}_U(z)$ the *modified fractional Rademacher sum of weight* 2κ *and order* μ *associated to* U.

We have the following vanishing result for fractional Rademacher sums.

Proposition 5.4.2. *Let* X *be a union of cosets of* $B(\mathbb{Z})$ *in* $G(\mathbb{Q})$, *let* $\mu=-g/h$ *for some* $g,h\in\mathbb{Z}^+$ *and* $(g,h)=1$, *and set* $U=\llbracket^hX$. *Suppose that the normalized fractional Rademacher sum* $T^{\kappa(\mu)}_U(z)$ *and the modified fractional Rademacher sum* $Q^{\kappa(\mu)}_U(z)$ *converge. Then they vanish identically unless* $h=1$.

Proof. Suppose that $h\neq1$. By hypothesis we have a disjoint decomposition $X=\bigcup_i\llbracket\chi_i$ for some $\{\chi_i\}\subset X$. This implies a disjoint decomposition $X=\bigcup_i\bigcup_{k=0}^{h-1}\llbracket^hT^k\chi_i$, so that we have

$$\begin{aligned}T^{\kappa(\mu)}_U(z,s)&=\sum_i\sum_{k=0}^{h-1}\mathrm{e}\left(-\frac{g}{h}T^k\chi_i\cdot z\right)\mathrm{t}^\kappa\left(-\frac{g}{h},T^k\chi_i,z,s\right)\mathrm{jac}(T^k\chi_i,z)^\kappa\\&=\sum_i\left(\sum_{k=0}^{h-1}\mathrm{e}\left(-\frac{gk}{h}\right)\right)\mathrm{e}\left(-\frac{g}{h}\chi_i\cdot z\right)\mathrm{t}^\kappa\left(-\frac{g}{h},\chi_i,z,s\right)\mathrm{jac}(\chi_i,z)^\kappa\end{aligned} \tag{5.4.13}$$

since the continued fractional regularization factor is unaffected when the second argument is multiplied by an element of $B(\mathbb{Z})$ on the left. The sum $\sum_{k=0}^{h-1} \mathrm{e}(-gk/h)$ vanishes for g coprime to h unless $h = 1$. This shows that the continued fractional Rademacher sum $T_U^{\kappa(\mu)}(z,s)$ vanishes for all z and s when $h \neq 1$. A directly analogous computation shows that the function $T_{0,U}^{\kappa(\mu)}(s)$ vanishes in case $h \neq 1$. We conclude that both the continued fractional Rademacher sum $T_U^{\kappa(\mu)}(z,s)$ and the modified continued fractional Rademacher sum $Q_U^{\kappa(\mu)}(z,s)$ vanish identically in case $h \neq 1$. The claim of the proposition follows. □

We return now to the identification of the Rademacher sum $Q_U^{\kappa(m)}(z)$, in the case that $U = \llbracket [\mu]\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}[1/\nu]$.

Theorem 5.4.3. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps for Γ, and let Σ_{p} and Σ_{q} be scaling cosets for Γ at p and q, respectively. Let $\mu,\nu \in \mathbb{Q}^+$ and set $U = \llbracket [\mu]\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}[1/\nu]$. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Let h be the smallest positive integer such that $h\mu \in \mathbb{Z}$. If h divides m then we have*

$$Q_U^{\kappa(m)}(z) = h\frac{\mu^\kappa}{\nu^\kappa} Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m\mu)}\left(\frac{z}{\nu}\right), \tag{5.4.14}$$

and if h does not divide m then $Q_U^{\kappa(m)}(z)$ vanishes identically.

Proof. Set $U' = \llbracket [\mu]\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$ and $U'' = \llbracket \Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}}$, so that $U = U'[1/\nu] = [\mu]U''[1/\nu]$. By Lemma 5.4.1 we have $Q_U^{\kappa(m)}(z) = Q_{U'}^{\kappa(m)}(z/\nu)/\nu^\kappa$, so it suffices for us to show that $Q_{U'}^{\kappa(m)}(z)$ is $h\mu^\kappa Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m\mu)}(z)$ or vanishing, according as h divides m or not.

Set $X = \Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{q}} \subset G(\mathbb{Q})$. Then X is a union of right cosets of $B(\mathbb{Z})$, so we have a disjoint decomposition $X = \bigcup_i \llbracket \chi_i$ for some $\chi_i \in G(\mathbb{Q})$. By the choice of h we have $\mu = g/h$ for some $g \in \mathbb{Z}^+$ with $(g,h) = 1$. Then for the set $[\mu]X$ we have

$$[\mu]X = \bigcup_i [\mu] \llbracket \chi_i = \bigcup_i \bigcup_{k=0}^{h-1} [\mu]T^k \llbracket^h \chi_i = \bigcup_i \bigcup_{k=0}^{h-1} T^{k\mu} \llbracket^g [\mu]\chi_i \tag{5.4.15}$$

with all the unions disjoint, from which we conclude that $\llbracket [\mu]X$ admits the disjoint decomposition $\llbracket [\mu]X = \bigcup_{k=0}^{h-1} \bigcup_i T^{k\mu} \llbracket [\mu]\chi_i$. We have

$$Q_{T^{k\mu}\llbracket [\mu]\chi_i}^{\kappa(m)}(z,s) = \mathrm{e}(mk\mu) Q_{\llbracket [\mu]\chi_i}^{\kappa(m)}(z,s). \tag{5.4.16}$$

If h divides m then $m\mu \in \mathbb{Z}$ and $\mathrm{e}(mk\mu) = 1$ for all k. Further, $Q_{\llbracket [\mu]\chi_i}^{\kappa(m)}(z,s)$ coincides with $\mu^\kappa Q_{\llbracket \chi_i}^{\kappa(m\mu)}(z,s)$ in this case, and so we deduce the required identity $Q_{U'}^{\kappa(m)}(z) = h\mu^\kappa Q_{\Gamma,\mathsf{p}|\mathsf{q}}^{\kappa(m\mu)}(z)$. On the other hand, if h does not divide m, so that $m\mu$ is not an integer, then the sum $\sum_{k=0}^{h-1} \mathrm{e}(mk\mu)$ vanishes and this implies the vanishing of the modified Rademacher sum $Q_{U'}^{\kappa(m)}(z)$. The proof is complete. □

Taking $\mathsf{q} = \Gamma \cdot \infty$ in Theorem 5.4.3 we obtain the following result.

Theorem 5.4.4. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let Z be a finite union of left cosets of Γ in $G(\mathbb{Q})$ and set $U = [\![Z$. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then the modified Rademacher sum $Q_U^{\kappa(m)}(z)$ is an automorphic integral of weight 2κ for Γ.*

5.5 Hecke operators

For the modified Rademacher sums, in contrast to the classical Rademacher sums, it is natural to consider not only their variance with respect to group actions, but also how they vary with respect to Hecke operators. The discrepancy in constant terms between the classical and modified Rademacher sums illustrated by Proposition 4.4.10 is a stubborn barrier to an exposition of the interaction between Hecke operators and the classical Rademacher sums.

Recall that $I_\kappa(\Gamma)$ denotes the space of automorphic integrals of weight 2κ for Γ, in the sense of §2.7, and recall the operator $I_\kappa(\Gamma) \to \mathcal{O}(\mathbb{H})$ of (2.7.14), denoted $f \mapsto f\|_\Gamma^\kappa X$, and defined for a right coset $X \in \Gamma\backslash G(\mathbb{Q})$ by setting $f\|_\Gamma^\kappa X = (f - J^\kappa_{\chi\cdot\infty} g)|^\kappa \chi$ for any representative $\chi \in X$ where $g \in S_{1-\kappa}(\Gamma)$ is the cusp form associated to f (cf. (2.7.13)). Let us generalize this operator by setting

$$f\|_\Gamma^\kappa X = \sum_i (f - J^\kappa_{\chi\cdot\infty} g)|^\kappa \chi_i \tag{5.5.1}$$

in case X is a finite union of right cosets of Γ in $G(\mathbb{Q})$ and the χ_i furnish a transversal $X = \bigcup_i \Gamma\chi_i$ for X over Γ. The next lemma verifies that the operator $f \mapsto f\|_\Gamma^\kappa X$ makes sense in case X is a double coset $X = \Gamma\sigma\Gamma$ of Γ in $G(\mathbb{Q})$.

Lemma 5.5.1. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let $\sigma \in G(\mathbb{Q})$, set $\Delta = \Gamma \cap \sigma^{-1}\Gamma\sigma$ and $\Delta' = \sigma\Gamma\sigma^{-1} \cap \Gamma$, and suppose that*

$$\Gamma = \bigcup_i \lambda_i'\Delta', \quad \Gamma = \bigcup_i \Delta\rho_i, \tag{5.5.2}$$

are left and right transversals for Γ over Δ' and Δ, respectively. Then the double coset $\Gamma\sigma\Gamma$ admits disjoint decompositions

$$\Gamma\sigma\Gamma = \bigcup_i \lambda_i'\sigma\Gamma, \quad \Gamma\sigma\Gamma = \bigcup_i \Gamma\sigma\rho_i, \tag{5.5.3}$$

into left and right cosets for Γ.

Proof. Since $G(\mathbb{Q})$ is the commensurator of $G(\mathbb{Z})$, the intersection $\Delta = \Gamma \cap \sigma^{-1}\Gamma\sigma$ has finite index in both Γ and $\sigma^{-1}\Gamma\sigma$, so there are only finitely many λ_i' and ρ_i. Observe next that

$\sigma\Delta = \Delta'\sigma = \sigma\Gamma \cap \Gamma\sigma$. Consequently, we have $\Delta'\sigma \subset \sigma\Gamma$ and $\sigma\Delta \subset \Gamma\sigma$, so that

$$\Gamma\sigma\Gamma = \bigcup \lambda_i'\Delta'\sigma\Gamma \subset \bigcup \lambda_i'\sigma\Gamma\Gamma = \bigcup \lambda_i'\sigma\Gamma, \tag{5.5.4}$$

$$\Gamma\sigma\Gamma = \bigcup \Gamma\sigma\Delta\rho_i \subset \bigcup \Gamma\Gamma\sigma\rho_i = \bigcup \Gamma\sigma\rho_i. \tag{5.5.5}$$

The reverse inclusions hold since all the λ_i' and ρ_i lie in Γ. The unions are disjoint, for if $\Gamma\sigma\rho_i = \Gamma\sigma\rho_j$ say, then $\rho_i\rho_j^{-1} \in \sigma^{-1}\Gamma\sigma$, but $\rho_i\rho_j^{-1} \in \Gamma$ by our choice of the ρ_i, so $\rho_i\rho_j^{-1} \in \Delta$, and this implies $i = j$. A similar argument applies to the cosets $\lambda_i'\sigma\Gamma$. □

The right hand identity of (5.5.3) shows that the operator $f \mapsto f\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma$ is well-defined for $f \in I_\kappa(\Gamma)$ and $\sigma \in G(\mathbb{Q})$. The left hand identity of (5.5.3) shows that the function $f\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma$ again lies in $I_\kappa(\Gamma)$. Indeed, if the cusp form associated to $f \in I_\kappa(\Gamma)$ is $g \in S_{1-\kappa}(\Gamma)$ then the cusp form associated to $f\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma$ is $g\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma$. We call the operator $I_\kappa(\Gamma) \to I_\kappa(\Gamma)$ given by $f \mapsto f\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma$ the *weight 2κ Hecke operator associated to σ*. In order to ease notation we set

$$f\dagger^{\kappa}_{\Gamma}\sigma = f\|^{\kappa}_{\Gamma}\Gamma\sigma\Gamma \tag{5.5.6}$$

for $\sigma \in G(\mathbb{Q})$. We have $f\dagger^{\kappa}_{\Gamma}\sigma = \sum_i f|^{\kappa}\chi_i$ when $\{\chi_i\} \subset G(\mathbb{Q})$ is a right transversal $\Gamma\sigma\Gamma = \bigcup_i \Gamma\chi_i$ for Γ in $\Gamma\sigma\Gamma$. If σ belongs to the normalizer of Γ then we have $\Gamma\sigma\Gamma = \Gamma\sigma$ and hence $f\dagger^{\kappa}_{\Gamma}\sigma = (f - J^{\kappa}_{\sigma\cdot\infty}g)|^{\kappa}\sigma$ for any $f \in I_\kappa(\Gamma)$. More generally, Lemma 5.5.1 yields for us the formula

$$f\dagger^{\kappa}_{\Gamma}\sigma = \sum_i (f - J^{\kappa}_{\sigma\rho_i\cdot\infty}g)|^{\kappa}(\sigma\rho_i) \tag{5.5.7}$$

in the case that $\{\rho_i\}$ is a right transversal for Γ over the intersection $\Delta = \Gamma \cap \Gamma^\sigma$.

The action of the operator $f \mapsto f\|^{\kappa}_{\Gamma}X$ on holomorphic Poincaré series can be described without reference to transversals. Indeed, if U is the set of right cosets of $B(\mathbb{Z})$ determined by a union of left cosets of some group Γ commensurable with $G(\mathbb{Z})$, and if X is a finite union $\bigcup_j \Gamma\chi_j$ say, of right cosets of Γ, then, taking $\kappa > 1$ to ensure absolute (and locally uniform) convergence, we have

$$P^{\kappa(m)}_{U}\|^{\kappa}_{\Gamma}X = \sum_j P^{\kappa(m)}_{U}|^{\kappa}\chi_j = \sum_j P^{\kappa(m)}_{U\chi_j} = P^{\kappa(m)}_{UX}, \tag{5.5.8}$$

so that the Poincaré series are stable under the action of the operators $f \mapsto f\|^{\kappa}_{\Gamma}X$. In particular, for the Hecke operator $f \mapsto f\dagger^{\kappa}_{\Gamma}\sigma$ we have $P^{\kappa(m)}_{U}\dagger^{\kappa}_{\Gamma}\sigma = P^{\kappa(m)}_{U\sigma\Gamma}$. This identity $P^{\kappa(m)}_{U}\|^{\kappa}_{\Gamma}X = P^{\kappa(m)}_{UX}$ extends naturally to the modified Rademacher sums.

Proposition 5.5.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$, let Z be a finite union of left cosets of Γ in $G(\mathbb{Q})$ and set $U = \llbracket Z$. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. Then for X a* *finite union of right cosets of* Γ *in* $G(\mathbb{Q})$ *we have*

$$Q_U^{\kappa(m)}\|_\Gamma^\kappa X = Q_{UX}^{\kappa(m)}. \tag{5.5.9}$$

Proof. The modified Rademacher sum $Q_U^{\kappa(m)}(z)$ is an automorphic integral of weight 2κ for Γ according to Theorem 5.4.4, so it has an associated cusp form $g \in S_{1-\kappa}(\Gamma)$ say. We may express X as a disjoint union $X = \bigcup_i \Gamma\chi_i$ for some finitely many $\chi_i \in G(\mathbb{Q})$. We then compute

$$Q_U^{\kappa(m)}\|_\Gamma^\kappa X = \sum_i (Q_U^{\kappa(m)} - J_{\chi_i\cdot\infty}^\kappa g)|^\kappa \chi_i = \sum_i Q_{U\chi_i}^{\kappa(m)} = Q_{UX}^{\kappa(m)}. \tag{5.5.10}$$

This proves the claim. □

In the case that Γ is the modular group $G(\mathbb{Z})$ we have the classical Hecke operators $\hat{T}(n)$, defined for $n \in \mathbb{Z}^+$ by setting

$$n^{1-\kappa}(\hat{T}(n)f)(z) = \sum_{\substack{ad=n\\ 0\leq b<d}} f\left(\frac{az+b}{d}\right)\frac{a^\kappa}{d^\kappa} \tag{5.5.11}$$

for $f \in M_\kappa(\Gamma)$. We deduce the relation between the operators $\hat{T}(n)$ and $f \mapsto f\dagger_\Gamma^\kappa\sigma$, for $\Gamma = G(\mathbb{Z})$, by observing the following coincidence of disjoint unions of cosets and double cosets of Γ.

$$\bigcup_{\substack{ad=n\\ 0\leq b<d}} \Gamma\begin{bmatrix} a & b\\ 0 & d\end{bmatrix} = \bigcup_{\substack{ad=n\\ d|a}} \Gamma\begin{bmatrix} a & 0\\ 0 & d\end{bmatrix}\Gamma \tag{5.5.12}$$

Both sides of (5.5.12) are decompositions of the image in $G(\mathbb{Q})$ of the set of 2×2 matrices with integral entries and determinant n. From these decompositions we deduce the following result.

Lemma 5.5.3. *For* $n \in \mathbb{Z}^+$ *and* $\kappa \in \mathbb{Z}$ *we have*

$$n^{1-\kappa}(\hat{T}(n)f) = \sum_{d\in\mathbb{Z}^+,\, d^2|n} f\dagger_\Gamma^\kappa[n/d^2] \tag{5.5.13}$$

for any $f \in I_\kappa(\Gamma)$.

As a partial converse to Lemma 5.5.3, observe that for $\Gamma = G(\mathbb{Z})$ the action of any Hecke operator $f \mapsto f\dagger_\Gamma^\kappa\sigma$ can be expressed in terms of the Hecke operator associated to a diagonal element $[\mu] \in B(\mathbb{Q})$. Indeed, if $\sigma \in B(\mathbb{Q})$ then, according to (5.5.12), we have $\Gamma\sigma\Gamma = \Gamma[\mu]\Gamma$ for some $\mu \in \mathbb{Q}^+$. In case σ does not lie in $B(\mathbb{Q})$ we have $\sigma\cdot\infty = p \neq \infty$ for some $p \in \mathbb{Q}$. Since the modular group acts transitively on $\hat{\mathbb{Q}}$ there is some $\sigma_p \in \Gamma$ with $\sigma_p\cdot\infty = p$, and then $\Gamma\sigma\Gamma = \Gamma\tilde{\sigma}\Gamma$ where $\tilde{\sigma} = \sigma_p^{-1}\sigma$ evidently lies in $B(\mathbb{Q})$.

Lemma 5.5.4. *Let $\Gamma = G(\mathbb{Z})$ and let $\sigma \in G(\mathbb{Q})$. Then there exists $\mu \in \mathbb{Q}^+$ such that*

$$f\dagger^{\kappa}_{\Gamma}\sigma = f\dagger^{\kappa}_{\Gamma}[\mu] \tag{5.5.14}$$

for all $\kappa \in \mathbb{Z}$ and all $f \in I_\kappa(\Gamma)$.

We now consider the action of the Hecke operators $\hat{T}(n)$ on the modified Rademacher sum $Q^{(-1)}_{\Gamma}(z) = Q^{(-1)}_{\llbracket\Gamma}(z)$ of weight 0 and order -1 associated to the modular group $\Gamma = G(\mathbb{Z})$. From Theorem 4.5.3 we have that $Q^{(-m)}_{\llbracket\Gamma}(z)$ is an automorphic integral of weight 0 (that is, an abelian integral) for Γ for $m > 0$. Since there are no non-zero cusp forms of weight 2 for the modular group, we see from Corollary 4.5.5 that $Q^{(-m)}_{\llbracket\Gamma}(z)$ is in fact a Γ-invariant function on $\mathbb{H}$ for all $m \in \mathbb{Z}^+$. Consequently we have $Q^{(-1)}_{\llbracket\Gamma}\dagger^{0}_{\Gamma}[n] = Q^{(-1)}_{\llbracket\Gamma[n]\Gamma}$ for $n \in \mathbb{Z}^+$, by Proposition 5.5.2 and the definition (5.5.6) of $f\dagger^{\kappa}_{\Gamma}\sigma$. Suppose that n is square-free. Then, according to Lemma 5.5.3, the action of the operator $f \mapsto f\dagger^{0}_{\Gamma}[n]$ on $M_0(\Gamma)$ coincides with that of $n\hat{T}(n)$. We anticipate an application of Lemma 5.5.1. For $\sigma = [n]$ we have $\Delta' = \sigma\Gamma\sigma^{-1} \cap \Gamma = \Gamma^0(n)$, and for a left transversal of $\Delta' = \Gamma^0(n)$ in Γ we may take

$$\Gamma = \bigcup_{e\|n} \bigcup_{k=0}^{n/e-1} T^k S T^e \Delta' \tag{5.5.15}$$

where the first union is over exact divisors of n (cf. §2.1). We deduce that

$$\Gamma[n]\Gamma = \bigcup_{e\|n} \bigcup_{k=0}^{n/e-1} T^k S T^e [n]\Gamma \tag{5.5.16}$$

by Lemma 5.5.1. Now $\llbracket T^k X = \llbracket X$ for any subset $X \subset G(\mathbb{Q})$ and any $k \in \mathbb{Z}$, so we find that

$$n(\hat{T}(n)Q^{(-1)}_{\llbracket\Gamma}) = Q^{(-1)}_{\llbracket\Gamma[n]\Gamma} = \sum_{e\|n} Q^{(-1)}_{\llbracket ST^e[n]\Gamma}. \tag{5.5.17}$$

Lemma 5.5.5. *Let e be an exact divisor of n. Then we have $\llbracket ST^e[n]\Gamma = \llbracket[n/e^2]\Gamma$ when Γ is the modular group $G(\mathbb{Z})$.*

Proof. We compute

$$ST^e[n] = \begin{bmatrix} 0 & -1 \\ n & e \end{bmatrix}, \quad ST^e[n]ST^{n/e}S = \begin{bmatrix} n/e & -1 \\ 0 & e \end{bmatrix}, \tag{5.5.18}$$

and observe that $T^k A T^l = [n/e^2]$ for $k, l \in \mathbb{Z}$ such that $ke + ln/e = 1$, where A is given by $A = ST^e[n]ST^{n/e}S$. ☐

We can now write

$$n(\hat{T}(n)Q^{(-1)}_{\llbracket\Gamma}) = \sum_{e\|n} Q^{(-1)}_{\llbracket[n/e^2]\Gamma} \tag{5.5.19}$$

in the case that n is square-free, and we can employ the methods of §5.4 to rewrite (5.5.19) in terms of the fractional Rademacher sums. Observe that $B(g\mathbb{Z})[g/h] = [g/h]B(h\mathbb{Z})$. We thus have

$$\llbracket[\mu]\chi = \bigcup_{k=0}^{g-1} T^k \llbracket^g[\mu]\chi = \bigcup_{k=0}^{g-1} T^k[\mu] \llbracket^h\chi \tag{5.5.20}$$

for any $\chi \in G(\mathbb{Q})$ when $\mu = g/h$ with $g, h \in \mathbb{Z}^+$ and $(g,h) = 1$. We rewrite the right hand side of (5.5.19), taking $g = n/h$ and $h = e$, as

$$\sum_{h\|n} Q^{(-1)}_{\llbracket[n/h^2]\Gamma} = \sum_{h\|n} Q^{(-1)}_{[n/h^2]\llbracket^h\Gamma} = \sum_{h\|n} Q^{(-n/h^2)}_{\llbracket^h\Gamma}, \tag{5.5.21}$$

and thus obtain the following result, relating the actions of Hecke operators to the fractional Rademacher sums.

Theorem 5.5.6. *Let $n \in \mathbb{Z}^+$ be square-free and let $\Gamma = G(\mathbb{Z})$. Then we have*

$$n(\hat{T}(n)Q^{(-1)}_{\llbracket\Gamma}) = \sum_{h\|n} Q^{(-n/h^2)}_{\llbracket^h\Gamma} \tag{5.5.22}$$

where the sum is over the exact divisors of n.

It is interesting to compare the result (5.5.22) of Theorem 5.5.6 with the identity

$$n\left(\hat{T}(n)Q^{(-1)}_{\llbracket\Gamma}\right)(z) = Q^{(-n)}_{\llbracket\Gamma}(z), \tag{5.5.23}$$

which holds since both sides are holomorphic on $\mathbb{H}$, and have the same singular terms in their Fourier expansion at $\Gamma \cdot \infty$. This proves that the Rademacher sum $Q^{(n/h^2)}_U(z)$ vanishes for $U = \llbracket^h\Gamma$ whenever h is an exact divisor of n, and thus recovers a special case of the vanishing result of Theorem 5.4.3.

6 Moonshine

Monstrous moonshine associates a group Γ_g commensurable with $G(\mathbb{Z})$ and having width one at infinity to each (conjugacy class of) element(s) g in the Monster group $\mathbb{M}$. In the article [CMS04] the set of groups $\{\Gamma_g \mid g \in \mathbb{M}\}$ is characterized in purely group theoretic terms. In this section we describe a reformulation of this characterization in terms of normalized Rademacher sums, and a certain family of moduli problems for solid tori with conformal structure on the boundary.

6.1 Genera

The main theorem of [CMS04] gives four conditions which, taken together, characterize the groups Γ_g for $g \in \mathbb{M}$. The first of these conditions is the requirement that a group Γ have genus zero. Our first result in this section is a reformulation of the genus zero condition in terms of Rademacher sums.

Theorem 6.1.1. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let p be a cusp for Γ. Then the normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ defines a Γ-invariant function on $\mathbb{H}$ if and only if Γ has genus zero.*

Proof. Let Γ be as in the statement of the theorem and let $\mathsf{p},\mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ. By Theorem 4.4.6 we have

$$T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z) = \delta_{\Gamma,\mathsf{p}|\mathsf{q}}\,\mathrm{e}(-z) + F^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)_{\mathrm{van}}. \tag{6.1.1}$$

Taking $\mathsf{q} = \Gamma \cdot \infty$ in (6.1.1) we see that $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is holomorphic on $\mathbb{H}$, and letting q range over P_Γ we see from (6.1.1) that the only pole of $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is a simple pole at the cusp p. We see then that if the function $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is Γ-invariant then it defines a morphism ϕ say, of Riemann surfaces $\phi : \mathsf{X}_\Gamma \to \hat{\mathbb{C}}$ (cf. §2.5) which has degree one since the preimage of $\infty \in \hat{\mathbb{C}}$ under ϕ is the single point $\mathsf{p} \in \mathsf{X}_\Gamma$ and ϕ is unramified here since Γ is assumed to have width one at infinity. We conclude that ϕ is an isomorphism, so that Γ indeed has genus zero.

Conversely, if Γ has genus zero then, since the space $S_1(\Gamma)$ of cusp forms of weight 2 for Γ is isomorphic to the space of holomorphic differentials on X_Γ, we have $S_1(\Gamma) = \{0\}$, so that any automorphic integral of weight 0 for Γ is in fact a Γ-invariant function, by Corollary 4.5.5. The modified Rademacher sum $Q^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is an automorphic integral for Γ by Theorem 4.5.3. The normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ differs from $Q^{(-1)}_{\Gamma,\mathsf{p}}(z)$ by a constant function by Proposition 4.4.11, and thus $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is Γ-invariant whenever $Q^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is. We conclude that $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ is Γ-invariant in case Γ has genus zero. This completes the proof. □

From the first part of the proof of Theorem 6.1.1 we see that the normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ associated to Γ at a cusp p defines an isomorphism $\mathsf{X}_\Gamma \to \hat{\mathbb{C}}$ mapping p to $\infty \in \hat{\mathbb{C}}$ in case Γ is a group of genus zero.

Theorem 6.1.2. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ. If Γ has genus zero then the normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}}(z)$ associated to Γ at the cusp p induces an isomorphism $\mathsf{X}_\Gamma \to \hat{\mathbb{C}}$ mapping p to ∞.*

Applying Theorem 6.1.2 with $\mathsf{p} = \Gamma \cdot \infty$ the infinite cusp we see that the normalized Rademacher sum $T_\Gamma^{(-1)}(z)$ induces an isomorphism $\mathsf{X}_\Gamma \to \hat{\mathbb{C}}$ mapping the infinite cusp to $\infty \in \hat{\mathbb{C}}$. Applying Proposition 4.4.9 with $\mathsf{p} = \mathsf{q} = \Gamma \cdot \infty$ we see that the Fourier expansion of $T_\Gamma^{(-1)}(z)$ has vanishing constant term. This shows that the normalized Rademacher sum $T_\Gamma^{(-1)}(z)$ associated to Γ at the infinite cusp is the normalized hauptmodul for Γ (cf. §2.5) whenever this statement makes sense; i.e. whenever Γ has genus zero.

Theorem 6.1.3. *Let Γ be a group commensurable with $G(\mathbb{Z})$ that has width one at infinity. If Γ has genus zero then the normalized Rademacher sum $T_\Gamma^{(-1)}(z)$ is the normalized hauptmodul for Γ.*

From the second part of the proof of Theorem 6.1.1 we see that if Γ has genus zero then not only the first order but in fact all the higher order normalized Rademacher sums $T_{\Gamma,\mathsf{p}}^{(-m)}(z)$ (for $m > 0$) associated to Γ at an arbitrary cusp $\mathsf{p} \in \mathsf{P}_\Gamma$ are Γ-invariant.

Theorem 6.1.4. *Let Γ be a subgroup of $G(\mathbb{Q})$ that is commensurable with $G(\mathbb{Z})$ and has width one at infinity and let $\mathsf{p} \in \mathsf{P}_\Gamma$ be a cusp of Γ. Let $m \in \mathbb{Z}^+$. If Γ has genus zero then the normalized Rademacher sum $T_{\Gamma,\mathsf{p}}^{(-m)}(z)$ is Γ-invariant.*

6.2 Moduli

The second condition of the main theorem of [CMS04] is that a group Γ be of $n\|h$-type (cf. §2.5). In this section we provide a geometric description of the groups of $n\|h$-type by furnishing a family of moduli problems for which the corresponding moduli spaces may be realized as quotients of the form $\mathsf{Y}_\Gamma = \Gamma\backslash\mathbb{H}$ where Γ is a group of $n\|h$-type.

Consider pairs (E, C) where E is an elliptic curve over $\mathbb{C}$ and C is an oriented subgroup of E isomorphic to S^1. We call such a pair a *solid torus*. For (E, C) a solid torus, we call E the *underlying elliptic curve*, and we call C the *underlying primitive cycle*. Note that for (E, C) a solid torus, the group C determines a primitive element of the first homology group of (the smooth real surface underlying) the elliptic curve E.

Given $z \in \mathbb{H}$ let us write Λ_z for the lattice $\mathbb{Z}z + \mathbb{Z} \subset \mathbb{C}$. Observe that the lattices Λ_z and $\Lambda_{z'}$ coincide if any only if $z - z' \in \mathbb{Z}$, so the assignment $z \mapsto \Lambda_z$ descends naturally to the orbit space $B(\mathbb{Z})\backslash\mathbb{H}$. If we agree to write $[\![z$ as a shorthand for the $B(\mathbb{Z})$ orbit determined by $z \in \mathbb{H}$, then we may unambiguously write $\Lambda_{[\![z}$ for the lattice $\mathbb{Z}z + \mathbb{Z}$. We write $E_{[\![z}$ for the corresponding elliptic curve $E_{[\![z} = \mathbb{C}/\Lambda_{[\![z} = \mathbb{C}/\mathbb{Z}z + \mathbb{Z}$. Then the pair $(E_{[\![z}, C_{[\![z})$ is a solid torus when we take the subgroup $C_{[\![z}$ to be the image of $\mathbb{R}$ in $E_{[\![z}$ under the composition $\mathbb{R} \to \mathbb{C} \to E_{[\![z}$. Observe that for any solid torus (E, C) there exists $z \in \mathbb{H}$ and a unique isomorphism of elliptic curves $E \to E_{[\![z}$ inducing an orientation preserving isomorphism $C \to C_{[\![z}$.

For (E, C) a solid torus and $n \in \mathbb{Z}^+$ we write $E[n]$ for the group of n-division points of E, and we write $C[n]$ for the intersection $C \cap E[n]$. Since C is oriented, each group $C[n]$ comes equipped with a distinguished generator; viz., the point corresponding to $1/n + \Lambda_{\llbracket z}$ under an isomorphism $E \to E_{\llbracket z}$ inducing an orientation preserving isomorphism $C \to C_{\llbracket z}$. If K is a subgroup of $E[n]$ for some n then the quotient $\bar{E} = E/K$ is again an elliptic curve, and the image $\bar{C}$ say, of C under the natural map $E \to \bar{E}$ defines a primitive cycle of $\bar{E}$, so that the pair $(\bar{E}, \bar{C})$ is again a solid torus. We call this the *quotient of* (E, C) *by* K and denote it $(E, C)/K$.

For $n \in \mathbb{Z}^+$ define an *n-compatible isogeny of solid tori* $(E', C') \to (E, C)$ to be an isogeny $E' \to E$ of elliptic curves that maps $C'[n]$ to a subgroup of $C[n]$. Then a 1-compatible isogeny of solid tori is just an isogeny of the underlying elliptic curves. We define an *isogeny of solid tori* $(E', C') \to (E, C)$ to be an isogeny $E' \to E$ of elliptic curves that restricts to an orientation preserving map $C' \to C$ on the underlying primitive cycles. For (E, C) a solid torus and $n \in \mathbb{Z}^+$, we may now interpret the canonical map $E \to E/C[n]$ as defining an isogeny $(E, C) \to (E, C)/C[n]$ of solid tori. We call this isogeny the *canonical n-fold quotient of* (E, C).

Observe that the elliptic curve $E/C[n]$ underlying the quotient $(E, C)/C[n]$ both receives a natural map from E and maps naturally to E, for the quotient $E/E[n]$ is naturally isomorphic to E, and for the map $E/C[n] \to E$ we may take the composition $E/C[n] \to E/E[n] \xrightarrow{\sim} E$ where the first map is the natural projection and the second map is the isomorphism just mentioned. This map $E/C[n] \to E$ defines an isogeny $(E, C)/C[n] \to (E, C)$ of solid tori; indeed, it restricts to an isomorphism on the underlying primitive cycles. We call the isogeny $(E, C)/C[n] \to (E, C)$ of solid tori the *canonical n-fold cover of* (E, C).

Say an n-compatible isogeny of solid tori $(E', C') \to (E, C)$, for $n \in \mathbb{Z}^+$, is an *n-compatible isomorphism of solid tori* in case it admits an inverse n-compatible isogeny; i.e. an isogeny $E \to E'$ mapping $C[n]$ to a subgroup of $C'[n]$ such that the compositions $E' \to E \to E'$ and $E \to E' \to E$ are the identity maps on E' and E, respectively. Simply put, an n-compatible isomorphism of solid tori $(E', C') \to (E, C)$ is an isomorphism of the underlying elliptic curves $E' \to E$ that induces an isomorphism of groups $C'[n] \to C[n]$. An *isomorphism of solid tori* $(E', C') \to (E, C)$ is an isomorphism $E' \to E$ of elliptic curves that restricts to an orientation preserving isomorphism $C' \to C$ on the underlying primitive cycles.

Suppose (E, C) and (E', C') are solid tori. For n a positive integer and e an exact divisor of n, say (E, C) and (E', C') are *$n+e$-related* if there is an n-compatible isogeny $(E', C') \to (E, C)$ that induces n/e-compatible isomorphisms $(E', C')/C'[e] \to (E, C)$ and $(E', C') \to (E, C)/C[e]$. More precisely, we require that the n-compatible isogeny $(E', C') \to (E, C)$ factor through the canonical e-fold maps $(E', C') \to (E', C')/C'[e]$ and $(E, C)/C[e] \to (E, C)$, defining n/e-

compatible isomorphisms of the specified type.

$$\begin{tikzcd}
(E',C') \arrow[r, "\sim", "n/e"'] \arrow[d] & (E,C)/C[e] \arrow[d] \\
(E',C')/C'[e] \arrow[r, "\sim", "n/e"'] & (E,C)
\end{tikzcd} \tag{6.2.1}$$

Then solid tori (E,C) and (E',C') are $n+1$-related just if they are n-compatible isomorphic, which is the case just if there is an isomorphism of elliptic curves $E' \to E$ mapping $C'[n]$ onto $C[n]$. In particular, the notion of being $n+1$-related is an equivalence relation on solid tori. For S a subset of the set of exact divisors of n, say solid tori (E,C) and (E',C') are *$n+S$-related* if (E,C) and (E',C') are $n+e$-related for some $e \in S$.

Recall from §2.2 that the set of exact divisors of n, denoted $\mathrm{Ex}(n)$, admits a naturally defined group structure.

Lemma 6.2.1. *Let $n \in \mathbb{Z}^+$ and let $S \subset \mathrm{Ex}(n)$. Then the $n+S$-relation is an equivalence relation on solid tori if and only if S is a subgroup of* $\mathrm{Ex}(n)$.

In light of Lemma 6.2.1, we say that solid tori (E,C) and (E',C') are *$n+S$-equivalent* if they are $n+S$-related and S is a subgroup of the group of exact divisors of n.

In a slight modification of the notation of [CN79], we write $\Gamma_0(n)+S$ for the group formed by taking the union of the Hecke congruence group $\Gamma_0(n)$ and the Atkin–Lehner involutions $W_e(n)$ for e in S, when S is a subgroup of $\mathrm{Ex}(n)$.

$$W_e(n) = \left\{ \begin{bmatrix} ae & b \\ cn & de \end{bmatrix} \in G(\mathbb{Q}) \mid a,b,c,d \in \mathbb{Z},\, ade - bcn/e = 1 \right\} \tag{6.2.2}$$

Let n be a positive integer and let h be a divisor of n. Then an n-compatible isomorphism $\phi : (E',C') \to (E,C)$ naturally determines an nh-compatible isogeny $\hat{\phi} : (E',C') \to (E,C)$ which factors through an n/h-compatible isomorphism $\bar{\phi} : (E',C')/C'[h] \to (E,C)/C[h]$ on the canonical h-fold quotients, via the canonical maps $(E',C') \to (E',C')/C'[h]$ and $(E,C)/C[h] \to (E,C)$, as depicted in (6.2.3).

$$\begin{tikzcd}
(E',C') \arrow[r, "\hat{\phi}", "nh"'] \arrow[d] & (E,C) \\
(E',C')/C'[h] \arrow[r, "\bar{\phi}", "n/h"'] & (E,C)/C[h] \arrow[u]
\end{tikzcd} \tag{6.2.3}$$

We may take this nh-compatible isogeny $\hat{\phi}$ to be the composition $E' \to E \to E/E[h] \to E$ where the first map is the given map ϕ, the second map is the natural projection, and the third map is the natural isomorphism. Since ϕ is an n-compatible isomorphism the composition $E' \to E \to E/E[h]$ factors through the natural projection $E/C[h] \to E/E[h]$, and the kernel of the induced map $E' \to E/C[h]$ is just $C'[h]$, and so we arrive at an isomorphism $E'/C'[h] \to E/C[h]$ of elliptic curves, which defines the required n/h-compatible isomorphism $\bar{\phi} : (E', C')/C'[h] \to (E, C)/C[h]$ of the corresponding solid tori.

$$\begin{tikzcd}
(E', C') \arrow[r, "\phi", "n"'] \arrow[dr] & (E, C) \arrow[r] & (E, C)/E[h] \arrow[r, "\sim"] & (E, C) \\
& (E', C')/C'[h] \arrow[r, "\bar{\phi}", "n/h"'] & (E, C)/C[h] \arrow[u] \arrow[ur] &
\end{tikzcd} \tag{6.2.4}$$

More generally, and by the same argument, an n-compatible isogeny $(E', C') \to (E, C)$ naturally defines an nh-compatible isogeny $(E', C') \to (E, C)$ which factors through an n/h-compatible isogeny $(E', C')/C'[h] \to (E, C)/C[h]$, via the canonical maps $(E', C') \to (E', C')/C'[h]$ and $(E, C)/C[h] \to (E, C)$.

Not every n/h-compatible isogeny $\bar{\phi} : (E', C')/C'[h] \to (E, C)/C[h]$ arises in this way from an n-compatible isogeny $\phi : (E', C') \to (E, C)$, but, given an n/h-compatible isogeny $\bar{\phi} : (E', C')/C'[h] \to (E, C)/C[h]$, we always have the nh-compatible isogeny $\hat{\phi} : (E', C') \to (E, C)$ obtained as the composition

$$(E', C') \to (E', C')/C'[h] \to (E, C)/C[h] \to (E, C) \tag{6.2.5}$$

where the first map is the canonical h-fold quotient, and the third map is the canonical h-fold cover. We call this composition $\hat{\phi}$ the *nh-compatible isogeny induced from $\bar{\phi}$*.

For $n \in \mathbb{Z}^+$ and h a divisor of n say solid tori (E, C) and (E', C') are *$n|h$-related* if the canonical h-fold quotients $(E, C)/C[h]$ and $(E', C')/C'[h]$ are n/h-compatible isomorphic. For e an exact divisor of n/h, say (E, C) and (E', C') are *$n|h + e$-related* if the quotients $(E, C)/C[h]$ and $(E', C')/C'[h]$ are $n/h + e$-related. For S a subset of $\mathrm{Ex}(n/h)$ say (E, C) and (E', C') are *$n|h + S$-related* if they are $n|h + e$-related for some $e \in S$.

Lemma 6.2.2. *Let $n \in \mathbb{Z}^+$, let h be a divisor of n, and let $S \subset \mathrm{Ex}(n/h)$. Then the $n|h + S$-relation is an equivalence relation on solid tori if and only if S is a subgroup of $\mathrm{Ex}(n/h)$.*

Let N be a positive integer, set $h = ((N, 24)$ (cf. §2.2), and set $n = N/h$. Then for S a subgroup of the group of exact divisors of n/h we arrive at the notion of $n\|h + S$-equivalence of solid tori in the following way. Suppose (E, C) and (E', C') are $\Gamma_0(n|h) + S$-equivalent. Then we have isomorphisms $(E,C)\to(E_{\llbracket z},C_{\llbracket z})$ and $(E',C')\to(E_{\llbracket z'},C_{\llbracket z'})$ for some $z,z'\in\mathbb{H}$. Let S' be the image of S under the natural injection $\mathrm{Ex}(n/h)\to\mathrm{Ex}(N)$ (cf. §2.2), and define elements x, y and $w_{e'}$ for $e'\in S'$ by setting

$$x=\begin{bmatrix}1&1/h\\0&1\end{bmatrix},\quad y=\begin{bmatrix}1&0\\n&1\end{bmatrix},\quad w_{e'}=\begin{bmatrix}ae'&b\\cN&de'\end{bmatrix},\tag{6.2.6}$$

where the a, b, c and d in the definition of $w_{e'}$ are arbitrary integers for which we have $ade'-bcN/e'=1$. Then there is a sequence $(\gamma_0,\gamma_1,\cdots,\gamma_k)$ with $\gamma_0\in\Gamma_0(N)$ and $\gamma_i\in\{x,y,w_{e'}\mid e'\in S'\}$ for $1\le i\le k$ for which we have $z'=\gamma_k\cdots\gamma_1\gamma_0\cdot z$. We say now that (E,C) and (E',C') are $\Gamma_0(n\|h)+S$*-equivalent* in the case that the sum $\sum_{i=1}^k\lambda(\gamma_i)$ vanishes in $\mathbb{Z}/h$, where $\lambda(x)=1$, and $\lambda(w_{e'})=0$ for all $e'\in S'$, and $\lambda(y)$ is -1 or 1 according as $\Gamma_0(n|h)+S$ is Fricke or not.

Theorem 6.2.3. *Let $N\in\mathbb{Z}^+$, set $h=((N,24)$ and set $n=N/h$. Let S be a subgroup of $\mathrm{Ex}(n/h)$, and set $\Gamma=\Gamma_0(n\|h)+S$. Then the quotient $\Gamma\backslash\mathbb{H}$ is in natural correspondence with $n\|h+S$-equivalence classes of solid tori.*

6.3 Exponents

The third of the four conditions of the main theorem of [CMS04] states that if Γ is of the form $\Gamma_0(n\|h)+S$ then the quotient group $\Gamma/\Gamma_0(nh)$ should be a group of exponent two. In the present section we investigate the relationship between this exponent two condition and properties of scaling cosets.

Lemma 6.3.1. *Suppose that Δ is a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{r}\in\mathsf{P}_\Delta$ be a cusp of Δ. Let $\kappa,m\in\mathbb{Z}$ such that $\kappa\le0$ and $m<0$. If Σ_r is a scaling coset for Δ at r with the property that $\Sigma_\mathsf{r}^2=\Delta$ then*

$$Q^{\kappa(m)}_{\Delta,\mathsf{r}}(z)=Q^{\kappa(m)}_{\Delta|\mathsf{r}}(z),\tag{6.3.1}$$

and Σ_r is contained in the normalizer of Δ.

Proof. Set $U=\llbracket\Sigma_\mathsf{r}^{-1}$ and set $U'=\llbracket\Sigma_\mathsf{r}$. Then, under the assumption that Δ has width one at infinity, we have $Q^{\kappa(m)}_{\Delta,\mathsf{r}}(z)=Q^{\kappa(m)}_{U}(z)$ and $Q^{\kappa(m)}_{\Delta|\mathsf{r}}(z)=Q^{\kappa(m)}_{U'}(z)$. Let $\sigma\in\Sigma_\mathsf{r}$. Then $\Sigma_\mathsf{r}^2=\Delta$ implies $\sigma\Delta\sigma=\Delta$, which is equivalent to the identity $\Delta\sigma=\sigma^{-1}\Delta$. We conclude that $\Sigma_\mathsf{r}^{-1}=\Sigma_\mathsf{r}$, so that $U=U'$, so that $Q^{\kappa(m)}_{\Delta,\mathsf{r}}(z)=Q^{\kappa(m)}_{\Delta|\mathsf{r}}(z)$. The identity $\sigma\Delta\sigma=\Delta$ also implies $\sigma^2\in\Delta$, so that $\sigma\Delta\sigma=\sigma^{-1}\Delta\sigma$. We conclude that σ normalizes Δ, so that $\Sigma_\mathsf{r}=\Delta\sigma\in\Delta\backslash N(\Delta)$. This completes the proof. □

Lemma 6.3.1 states that if a scaling coset at a cusp r of a group Δ can be chosen so that its square is the trivial coset then we have a kind of commutativity for the Rademacher sums associated to Δ; viz. the expansion at infinity of the modified Rademacher sum associated to Δ and the cusp r coincides with the expansion at r of the modified Rademacher sum associated to Δ and the cusp at infinity.

We also have the following converse to Lemma 6.3.1.

Proposition 6.3.2. *Suppose that Δ is a group commensurable with $G(\mathbb{Z})$ that has width one at infinity and let $\mathsf{r} \in \mathsf{P}_\Delta$ be a cusp of Δ. Let $\kappa, m \in \mathbb{Z}$ such that $\kappa \leq 0$ and $m < 0$. If Σ_r is a scaling coset for Δ at r that is contained in the normalizer of Δ and*

$$Q^{\kappa(m)}_{\Delta,\mathsf{r}}(z) = Q^{\kappa(m)}_{\Delta|\mathsf{r}}(z) \tag{6.3.2}$$

then $\Sigma_\mathsf{r}^2 = \Delta$.

Proof. As in the proof of Lemma 6.3.1 we set $U = \llbracket \Sigma_\mathsf{r}^{-1}$ and $U' = \llbracket \Sigma_\mathsf{r}$. Then since Δ is assumed to have width one at infinity we have $Q^{\kappa(m)}_{\Delta,\mathsf{r}}(z) = Q^{\kappa(m)}_{U}(z)$ and $Q^{\kappa(m)}_{\Delta|\mathsf{r}}(z) = Q^{\kappa(m)}_{U'}(z)$. Let $\sigma \in \Sigma_\mathsf{r}$. Then we have $U = \llbracket \sigma^{-1}\Delta$ and $U' = \llbracket \Delta\sigma = \llbracket \sigma\Delta$. Set $\mathsf{r}' = \Delta\sigma^{-1} \cdot \infty$. Then $Q^{\kappa(m)}_{U'}(z) = Q^{\kappa(m)}_{\Delta,\mathsf{r}'}(z)$, so the coincidence $Q^{\kappa(m)}_{U}(z) = Q^{\kappa(m)}_{U'}(z)$ implies that $\mathsf{r} = \mathsf{r}'$. This in turn implies $\sigma^2 \in \Delta$, so that $\Sigma_\mathsf{r}^2 = \Delta$, as we required to show. ☐

6.4 Cusps

The forth condition of the main theorem of [CMS04] is the following. Supposing that a group Γ is of the form $\Gamma = \Gamma_0(n\|h) + S$ for some subgroup S of the group of exact divisors of n/h, for each $p \in \hat{\mathbb{Q}}$ there should exist an element $\tilde{\sigma}_p \in G(\mathbb{R})$ such that

$$\infty = \tilde{\sigma}_p \cdot p, \quad (\tilde{\sigma}_p \Gamma \tilde{\sigma}_p^{-1})_\infty = B(\mathbb{Z}), \quad \tilde{\sigma}_p \Gamma \tilde{\sigma}_p^{-1} \supset \Gamma_0(nh). \tag{6.4.1}$$

Observe that if we set $\sigma_p = \tilde{\sigma}_p^{-1}$, then the conditions of (6.4.1) translate into

$$\sigma_p \cdot \infty = p, \quad (\sigma_p^{-1} \Gamma \sigma_p)_\infty = B(\mathbb{Z}), \quad \sigma_p^{-1} \Gamma \sigma_p \supset \Gamma_0(nh), \tag{6.4.2}$$

the first two of which are just the conditions (2.6.1) of Lemma 2.6.1 except that we allow σ_p to lie in $G(\mathbb{R})$ in (6.4.2) but insist that σ_p belong to $G(\mathbb{Q})$ in (2.6.1). Actually, an element $\sigma_p \in G(\mathbb{R})$ satisfying (6.4.2) must lie in $G(\mathbb{Q})$, as the following result demonstrates.

Lemma 6.4.1. *Let Δ and Γ be groups commensurable with $G(\mathbb{Z})$ and suppose that Δ has width one at infinity. Let $p \in \hat{\mathbb{Q}}$ and suppose that $\sigma \in G(\mathbb{R})$ satisfies $\sigma \cdot \infty = p$ and $\sigma^{-1}\Gamma\sigma \supset \Delta$. Then $\sigma \in G(\mathbb{Q})$.*

Proof. Suppose that $\sigma \in G(\mathbb{R})$ satisfies the hypotheses of the lemma. Then $(\sigma^{-1}\Gamma\sigma)_\infty$ is an infinite cyclic group containing Δ_∞ and $\Delta_\infty = B(\mathbb{Z})$ since Δ has width one at infinity. It must be then that $(\sigma^{-1}\Gamma\sigma)_\infty$ is generated by $T^{1/n}$ for some $n \in \mathbb{Z}^+$, so that $([n]\sigma^{-1}\Gamma\sigma[1/n])_\infty = B(\mathbb{Z})$. According to Lemma 2.6.1 there exists $\sigma' \in G(\mathbb{Q})$ such that $\sigma'\cdot\infty = p$ and $((\sigma')^{-1}\Gamma\sigma')_\infty = B(\mathbb{Z})$. Now $[n]\sigma^{-1}\sigma'$ fixes ∞ and so lies in $B(\mathbb{R})$. Since σ' and $\sigma[1/n]$ both conjugate Γ to a group with width one at infinity we must in fact have $[n]\sigma^{-1}\sigma' \in B_u(\mathbb{R})$, where $B_u(\mathbb{R})$ consists of all the elements T^α (cf. (2.3.4)) with $\alpha \in \mathbb{R}$. We conclude that $\sigma = \sigma'' T^\alpha$ for some $\sigma'' \in G(\mathbb{Q})$ and $\alpha \in \mathbb{R}$. Let $\gamma \in \Gamma$ such that $\sigma^{-1}\gamma\sigma \in \Delta^\times$, so that $\sigma^{-1}\gamma\sigma\cdot\infty = q$ for some $q \in \mathbb{Q}$. Then $q = q'' - \alpha$ for $q'' = (\sigma'')^{-1}\gamma\sigma''\cdot\infty$. Since both q and q'' lie in $\mathbb{Q}$ we conclude that α also lies in $\mathbb{Q}$. Then the identity $\sigma = \sigma''T^\alpha$ implies that $\sigma \in G(\mathbb{Q})$, as we required to show. ☐

Recall from §2.6 that for Γ a group commensurable with $G(\mathbb{Z})$, for $\mathsf{p} \in \mathsf{P}_\Gamma$ a cusp of Γ, and for $\Sigma_{\mathsf{p}} \in \Gamma\backslash G(\mathbb{Q})$ a scaling coset for Γ at p, we write Γ^{p} as a shorthand for the group $\Sigma_{\mathsf{p}}^{-1}\Sigma_{\mathsf{p}}$. In light of Lemma 6.4.1 we may reformulate the fourth condition of the main theorem of [CMS04] as follows.

Lemma 6.4.2. *Let Γ be a group of $n\|h$-type, so that $\Gamma = \Gamma_0(n\|h)+S$ for some positive integers n and h, and some subgroup S of the group of exact divisors of n/h. Then the fourth condition of the main theorem of [CMS04] is satisfied if and only if for each cusp $\mathsf{p} \in \mathsf{P}_\Gamma$ of Γ there exists a scaling coset $\Sigma_{\mathsf{p}} \in \Gamma\backslash G(\mathbb{Q})$ for Γ at p such that Γ^{p} contains $\Gamma_0(nh)$.*

We conclude this section by relating the reformulation of Lemma 6.4.2 to the normalized Rademacher sums associated to genus zero groups of $n\|h$-type.

Proposition 6.4.3. *Let Γ be a group of $n\|h$-type, so that $\Gamma = \Gamma_0(n\|h) + S$ for some positive integers n and h, and some subgroup S of the group of exact divisors of n/h, and suppose that Γ has genus zero. Let $\mathsf{p}, \mathsf{q} \in \mathsf{P}_\Gamma$ be cusps of Γ and let Σ_{p} and Σ_{q} be scaling cosets for Γ at p and q, respectively. Then the normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is $\Gamma_0(nh)$-invariant if and only if Γ^{q} contains $\Gamma_0(nh)$.*

Proof. Let us set $\Delta = \Gamma_0(nh)$. Observe that if we set $\mathsf{p}^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}\cdot\infty$ then p^{q} is a cusp of $\Gamma^{\mathsf{q}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{q}}$, and $\Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}$ is a scaling coset for Γ^{q} at p^{q}, so the function $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ may be identified with the normalized Rademacher sum $T^{(-1)}_{\Gamma^{\mathsf{q}},\mathsf{p}^{\mathsf{q}}}(z)$ associated to Γ^{q} at the cusp p^{q}, for $\Sigma_{\mathsf{p}^{\mathsf{q}}} = \Sigma_{\mathsf{q}}^{-1}\Sigma_{\mathsf{p}}$. Under the assumption that Γ has genus zero, Γ^{q} also has genus zero, and has width one at infinity by the defining properties (cf. Lemma 2.6.2) of Σ_{q}. By Theorem 6.1.3 then the normalized Rademacher sum $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is, up to a constant function, the expansion at p^{q} of the normalized hauptmodul of the group Γ^{q}. In particular, $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ defines an isomorphism of Riemann surfaces $\mathsf{X}_{\Gamma^{\mathsf{q}}} \to \hat{\mathbb{C}}$, and so we have $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(\gamma\cdot z) = T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ for all $z \in \mathbb{H}$ if and only if $\gamma \in \Gamma^{\mathsf{q}}$. It follows then that $T^{(-1)}_{\Gamma,\mathsf{p}|\mathsf{q}}(z)$ is Δ-invariant if and only if Δ is contained in Γ^{q}, which is what we required to show. ☐

6.5 Rademacher sums and the Monster

We will now use Rademacher sums to reformulate the characterization of the groups of monstrous moonshine due to Conway–McKay–Sebbar (cf. [CMS04]).

Theorem 6.5.1. *Let Γ be a subgroup of $G(\mathbb{R})$. Then we have $\Gamma = \Gamma_g$ for some $g \in \mathbb{M}$ if and only if the following conditions are satisfied:*

- *Γ is the group defining $n\|h + S$-equivalence of solid tori for some positive integers n and h, and some subgroup $S < \mathrm{Ex}(n/h)$;*
- *the normalized Rademacher sum $T_{\Gamma}^{(-1)}(z)$ is Γ-invariant;*
- *there exists a system $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_{\Gamma}\}$ of scaling cosets for Γ such that $T_{\Gamma|\mathsf{p}}^{(-1)}(z)$ is Δ-invariant for every cusp $\mathsf{p} \in \mathsf{P}_{\Gamma}$ of Γ, where $\Delta = \Gamma_0(nh)$;*
- *for every cusp $\mathsf{r} \in \mathsf{P}_{\Delta}$ of $\Delta = \Gamma_0(nh)$ that is contained in $\Gamma\cdot\infty$ we have $T_{\Delta,\mathsf{r}}^{(-1)}(z) = T_{\Delta|\mathsf{r}}^{(-1)}(z)$ when the scaling coset Σ_{r} for Δ at r is taken to lie in $\Delta\backslash\Gamma$.*

Proof. According to the main theorem of [CMS04] it suffices to show that a group Γ satisfies each of the four conditions of Theorem 6.5.1 if and only if it satisfies the four conditions of the main theorem of [CMS04]. As a first step in establishing this equivalence, observe that the first condition of Theorem 6.5.1 is exactly the same as the second condition of the main theorem of [CMS04].

Suppose that Γ satisfies the four conditions of the main theorem of [CMS04]. Then, in particular, it satisfies the first condition of Theorem 6.5.1, and has genus zero. We may suppose then that $\Gamma = \Gamma_0(n\|h) + S$ for some $n, h \in \mathbb{Z}^+$, and $S < \mathrm{Ex}(n/h)$, so that Γ is commensurable with $G(\mathbb{Z})$, has width one at infinity, and contains and normalizes $\Delta = \Gamma_0(nh)$. According to Theorem 6.1.1 the normalized Rademacher sum $T_{\Gamma}^{(-1)}(z)$ is Γ-invariant, so the second condition of Theorem 6.5.1 is satisfied. According to Lemma 6.4.2 there exists a system $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_{\Gamma}\}$ of scaling cosets for Γ such that Γ^{p} contains Δ for each cusp $\mathsf{p} \in \mathsf{P}_{\Gamma}$. Applying Proposition 6.4.3 we see that the normalized Rademacher sum $T_{\Gamma|\mathsf{p}}^{(-1)}(z)$ is Δ-invariant when the scaling coset Σ_{p} of the above scaling coset system is chosen for the definition of $T_{\Gamma|\mathsf{p}}^{(-1)}(z)$. This confirms that the third condition of Theorem 6.5.1 is satisfied. The fourth condition of the main theorem of [CMS04] is that the quotient Γ/Δ have exponent two. Let $\mathsf{r} \in \mathsf{P}_{\Delta}$ be a cusp of Δ that is contained in $\Gamma\cdot\infty$, and let Σ_{r} be the unique right coset of Δ in Γ such that $\mathsf{r} = \Sigma_{\mathsf{r}}\cdot\infty$. Then the exponent two condition implies $\Sigma_{\mathsf{r}}^2 = \Delta$, so that the fourth condition of Theorem 6.5.1 follows from an application of Lemma 6.3.1.

Suppose now that Γ satisfies the four conditions of Theorem 6.5.1. Then Γ satisfies the second condition of [CMS04], and so we have $\Gamma = \Gamma_0(n\|h) + S$ for some $n, h \in \mathbb{Z}^+$, and $S < \mathrm{Ex}(n/h)$, and Γ is a group commensurable with $G(\mathbb{Z})$ that has width one at infinity. Applying Theorem 6.1.1 to the second condition of Theorem 6.5.1 we conclude that Γ has genus zero, and so satisfies the first condition of [CMS04]. Set $\Delta = \Gamma_0(nh)$, so that Γ contains and normalizes Δ. Applying Proposition 6.4.3 to the third condition of Theorem 6.5.1 we see that scaling cosets $\{\Sigma_{\mathsf{p}} \mid \mathsf{p} \in \mathsf{P}_\Gamma\}$ can be chosen for Γ so that Γ^{p} contains Δ for each cusp $\mathsf{p} \in \mathsf{P}_\Gamma$. Applying Lemma 6.4.2 to this fact we conclude that Γ satisfies the fourth condition of the main theorem of [CMS04]. It remains to check that the quotient Γ/Δ has exponent two. Let $\gamma \in \Gamma$ and set $\mathsf{r} = \Delta\gamma \cdot \infty$. If we take $\Sigma_{\mathsf{r}} = \Delta\gamma$ then the fourth condition of Theorem 6.5.1 states that $T^{(-1)}_{\Delta|\mathsf{r}}(z) = T^{(-1)}_{\Delta,\mathsf{r}}(z)$. Proposition 6.3.2 now implies that $\Sigma_{\mathsf{r}}^2 = \Delta$, which in turn implies $\gamma^2 \in \Delta$. This argument applies to arbitrary $\gamma \in \Gamma$ so we conclude that the quotient Γ/Δ has exponent two. This completes the proof. □

Perhaps the most technical condition of Theorem 6.5.1 is the last one. Beyond the monstrous moonshine conjectures, there are the generalized moonshine conjectures of Norton (cf. [Mas87]) which associate genus zero groups to commuting pairs of elements in the Monster. A number of the groups appearing in generalized moonshine do not satisfy the last condition of Theorem 6.5.1, but they all satisfy the second property, and a slight weakening of the first (cf. [Fer93]), and we do not know of any examples that fail to satisfy the third condition of Theorem 6.5.1. It is an interesting question then to determine if the first three conditions of Theorem 6.5.1 furnish a characterization of the groups of generalized moonshine.

7 Gravity

In this section we consider applications of the normalized Rademacher sums to chiral 3d quantum gravity. We should note that the notion of chiral 3d quantum gravity has not yet been defined, so the applications we make, and in particular the conjectures we formulate, are intended to shed light on the very problem of formulating a definition, in addition to elucidating important structural properties that a certain distinguished (and conjectural) example might satisfy. In the absence of a precise definition of 3d quantum gravity some of our discussion in this section is necessarily more speculative.

7.1 First conjecture

It is clear from our results that the Rademacher sums are particularly convenient for understanding the special characteristics of the McKay–Thompson series; in particular, their crucial genus zero property. In order to fully explain the moonshine phenomena, one has to relate these sums to the structure of the vertex operator algebra $V^\natural$. In search for the new relation, one might look again for hints from physics. Very recently, Witten, revisiting 3d quantum gravity, has formulated a number of results and observations [Wit07] including a conjecture about the existence of the 3d quantum gravities with central charges $c_L = c_R$ proportional to

24. In particular, he asserted that the simplest in his list of 3d quantum gravities should be equivalent to the 2d conformal field theory $V^\natural \otimes (V^\natural)^*$. Manschot [Man07] then suggested to consider chiral 3d quantum gravities, the simplest of which, with $c_L = 24$ and $c_R = 0$, should be equivalent exactly to $V^\natural$. Furthermore, Li, Song and Strominger [LSS08] have argued that the chiral gravity possesses stability and consistency, the necessary properties of a sound physical theory. A very recent work [MSS09] by Maloney, Song and Strominger provided further support for the existence of chiral gravities with c_L proportional to 24. These results and observations from physics taken together suggest that there exists an alternative construction of the vertex operator algebra $V^\natural$ that may be viewed as a rigorous version of the simplest chiral 3d quantum gravity with $c = 24$, in the same way as the original construction of $V^\natural$ was interpreted as a rigorous version of the chiral 2d conformal field theory with the partition function $J(z)$. In 3d quantum gravity one expects to obtain the partition function as a sum over minimum points of a 3d quantum gravity action; i.e. over all 3d hyperbolic structures on a solid torus with genus one boundary, whose conformal structure corresponds to the point z on the moduli space. Since all such structures are naturally parameterized by $\Gamma_\infty \backslash PSL_2(\mathbb{Z})$ (cf. [DMMV00]), the partition function should be a kind of Rademacher sum. In fact Manschot and Moore [MM07] argued that the subtraction of constants in (1.2.1) can be explained by a regularization of the partition function of 3d gravity. Our continued Rademacher sums of §4, leading naturally to the modified and normalized Rademacher sums, provide a good candidate for such a regularization.

To obtain the McKay–Thompson series (1.1.3) from the chiral 3d quantum gravity is a more challenging problem even at the heuristic level. However, one may look at these series from a slightly different point of view. It has been shown in [DLM00] that for any $g \in \mathbb{M}$ there exists a unique simple g-twisted $V^\natural$-module $V^\natural_g$, whose partition function is equal to $c(g)T_g(-1/z)$ where $c(g)$ is a constant depending on $g \in \mathbb{M}$. The heuristic analysis of the twisted sector $V^\natural_g$ in [Tui95] strongly supports the general assumption that $c(g) = 1$ for all $g \in \mathbb{M}$. (For more on this assumption please see the discussion of “Hypothesis A_g” in [Car09].)

We now state our first conjecture.

Conjecture 7.1.1. *There exists a family of twisted chiral 3d quantum gravities at central charge $c = 24$ associated with elements of the Monster $g \in \mathbb{M}$ whose partition functions are naturally given by sums over geometries parameterized by $\Gamma_\infty\backslash\Gamma_g$, and these partition functions coincide with the normalized Rademacher sum $T^{(-1)}_\Gamma(-1/z)$, for $\Gamma = \Gamma_g$. Moreover, the untwisted ($g = e$) chiral 3d quantum gravity has a VOA structure isomorphic to $V^\natural$, and the twisted 3d quantum gravity corresponding to $g \in \mathbb{M}$ has a structure of g-twisted $V^\natural$-module isomorphic to that of $V^\natural_g$.*

The special case $g = e$ of Conjecture 7.1.1, corresponding to the untwisted chiral 3d quantum gravity, is strongly supported by the physics literature mentioned above. We will now make a few remarks about the general twisted case. The principle of the 3d quantum gravity/2d CFT correspondence suggests that all the structures in either theory should have appropriate counterparts in the other. The g-twisted sector $V_g^\natural$ is an intrinsic part of the extended theory of the chiral 2d CFT associated to $V^\natural$, and, according to the physical principle, should therefore have analogues in chiral 3d quantum gravity. Basic information about these twisted chiral 3d quantum gravities can be extracted from the Rademacher sums $J_g(z) = T_g(-1/z)$. We'll illustrate the general case with the level two examples, which are the cases that $\Gamma = \Gamma_0(2)$ or $\Gamma_0(2)+$. (In the notation of §2.5 the symbols $\Gamma_0(2)+$ are a shorthand for $\Gamma_0(2) + \mathrm{Ex}(2)$.) As in the case that $g = e$ one expects that each term of the Rademacher sum comes from a classical solution of the corresponding twisted chiral quantum gravity. Every Rademacher sum $J_g(z)$ contains the term $\mathrm{e}(1/z)$, which corresponds to the BTZ black hole solution (cf. [BTZ92]). The other terms arising for $\Gamma = \Gamma_0(2)$ can be characterized among all those arising for $\Gamma = G(\mathbb{Z})$ as the solutions that have the same spin structure as the BTZ black hole on the boundary. The Rademacher sum $J_g(z)$ in this case coincides with the partition function of the Ramond sector in supergravity (cf. [MW07, §7]). The group $\Gamma = \Gamma_0(2)+$ is no longer a subgroup of the modular group $G(\mathbb{Z})$. In this case we have to consider orbifold solutions in addition to smooth solutions; we consider orbifold solutions with a codimension 2 singularity along the defining circle of the solid torus which looks locally like $\mathbb{C}/\langle\, \mathrm{e}(1/2)\rangle$ (cf. [MW07, §2]), and we still impose the same spin structure boundary condition. Note that on any space X, choices of spin structure on X (when they exist) are in bijective correspondence with a particular family of double covers of X (cf. e.g. [LM89]). Such a double cover smooths the $\mathbb{Z}/2$-orbifold singularity. One may view the spin structure as a $\mathbb{Z}/2$-structure, and for a general level N group Γ, spin structures are replaced with $\mathbb{Z}/N$-structures. One can also allow singularities along the defining circle of the solid torus that look locally like $\mathbb{C}/\langle\, \mathrm{e}(1/N)\rangle$. In general, a choice of twisted gravity with $\mathbb{Z}/N$-structure group should impose an $n\|h + S$ equivalence for solid tori, for some n and h with $N = nh$ and h a divisor of 24 (cf. Theorem 6.2.3), which yields the Rademacher sum $J_g(z)$, for a corresponding $g \in \mathbb{M}$, as the saddle point approximation of the twisted quantum gravity partition function.

We expect that the conjectural twisted chiral 3d quantum gravity construction of $V_g^\natural$ will imply the Γ_g-invariance of its partition function, in analogy with the way in which 2d CFTs are found to have modular invariant partition functions (cf. [Wit87]). Then our conjecture, in combination with our results on Rademacher sums, will naturally imply the genus zero conjecture of Conway–Norton (cf. [CN79]), and most importantly, will reveal the geometric nature of moonshine. In particular, the solution to Conjecture 7.1.1 will answer the genus zero question: why the discrete groups attached to the Monster via monstrous moonshine all have genus zero.

We also expect that the conditions on Rademacher sums in our reformulation Theorem 6.5.1, of the group theoretic characterization of the groups of monstrous moonshine due to Conway–McKay–Sebbar, will also find an interpretation as consistency conditions for twisted chiral 3d quantum gravities. In particular, the completeness of the family of twisted chiral 3d quantum gravities at central charge 24 associated with elements of the Monster group $\mathbb{M}$ should have a deep meaning in quantum gravity.

Our Conjecture 7.1.1 should have significance for the future development of analytic number theory also. We already know from 2d CFT that various constructions yield remarkable number theoretic identities. Our conjecture implies that the development of the theory of 3d quantum gravity might encompass a whole new family of number theoretic results such as the theory of Rademacher sums studied in this work. In §7.3 we'll show that the Hecke operators also admit an interpretation in terms of quantum gravity. In preparation for this we will recall in the next section some results about a certain class of generalized Kac–Moody algebras and their representations.

7.2 Monstrous Lie algebras

In his paper [Bor92], Borcherds constructed a remarkable generalized Kac–Moody algebra (*GKM algebra*) $\mathfrak{m}$, called the *Monster Lie algebra*, which plays a key rôle in his approach to monstrous moonshine. He also defined GKM superalgebras $\mathfrak{m}'_g$, for each $g \in \mathbb{M}$, by using the McKay–Thompson series $T_g(z)$ to specify the simple roots. In this section we'll consider another family of GKM algebras $\mathfrak{m}_g$, parameterized by elements $g \in \mathbb{M}$, with simple roots specified by the functions $J_g(z) = T_g(-1/z)$. Since the Fourier coefficients of the $J_g(z)$ are non-negative integers, the algebras $\mathfrak{m}_g$ are purely even. We will also study Verma modules for the GKM algebras $\mathfrak{m}_g$.

In the following section §7.3, we will explain how these algebraic structures arise from the Rademacher sums, and the conjectural twisted chiral 3d quantum gravities. This will lead us to a further extension of our first conjecture.

The algebras $\mathfrak{m}_g$ were introduced and studied by Carnahan in [Car07] and were discovered independently by the second author. We will now recall the relevant results of [Car07].

Let $L = II_{1,1}$ denote a copy of the unique even self-dual Lorentzian lattice of rank 2. We identify L with the group $\mathbb{Z} \times \mathbb{Z}$ and set the norm of the pair (m, n) to be $-2mn$. For any positive integer N we denote the sublattice $\mathbb{Z} \times N\mathbb{Z}$ by $L(N)$, and we let $L(N)^\vee$ denote the dual lattice $\frac{1}{N}\mathbb{Z} \times \mathbb{Z}$. Let V_L denote the vertex operator algebra (VOA) associated to the lattice L (cf. [FLM88]),

$$V_L = \bigoplus_{(m,n)\in L} V_L^{(m,n)}, \tag{7.2.1}$$

and let h_N denote the automorphism of V_L which acts as multiplication by $\mathrm{e}(n/N)$ on the subspace $V_L^{(m,n)}$. Then $V_{L(N)}$ is a vertex operator subalgebra of $V_{L(N)}$ fixed by h_N. Following [DL93] each coset $L + (k/N, 0)$ of L in $L(N)^\vee$ defines an h_N^k-twisted module for V_L. We denote this twisted module by $V_{L+(k/N,0)}$, and regard it as graded in the natural way by $L + (k/N, 0)$.

For $g \in \mathbb{M}$ such that the level of Γ_g is N (i.e. $N = nh$ in the notation of [CN79]) define $W_g^\natural$

to be the following $L(N)^\vee$-graded space invariant under $\langle g\rangle$.

$$W_g^\natural = \bigoplus_{k=0}^{N-1} \left(V_{g^k}^\natural \otimes V_{L+(k/N,0)} \right)^{\langle g\rangle} \tag{7.2.2}$$

The summand corresponding to $k=0$ has a natural VOA structure, while the other summands are naturally modules for this VOA. There also exists a unique (up to scalar) intertwining operator between the product of the k-th and l-th summands and the $(k+l)$-th summand. Carnahan asserts that there is a consistent choice of these constants such that one has

Theorem 7.2.1. *The space $W_g^\natural$ naturally admits a VOA structure.*

By construction $W_g^\natural$ has rank 26 and one can define the semi-infinite cohomology of the Virasoro algebra with coefficients in $W_g^\natural$. The the first semi-infinite cohomology group acquires a Lie algebra structure according to [LZ95]. In this way we obtain a *monstrous Lie algebra* $\mathfrak{m}_g$ for each $g \in \mathbb{M}$.

$$\mathfrak{m}_g = H^{\infty/2+1}(W_g^\natural) \tag{7.2.3}$$

An alternative construction of $\mathfrak{m}_g$ may be based on the no-ghost theorem of the 26-dimensional bosonic string (cf. [Fre85], [Bor92]). For $g=e$, the Lie algebra $\mathfrak{m}_e$ is the original Monster Lie algebra of Borcherds [Bor92].

The Lie algebra $\mathfrak{m}_g$ inherits an $L(N)^\vee$-grading

$$\mathfrak{m}_g = \bigoplus_{m,n\in\mathbb{Z}} \mathfrak{m}_g^{(m/N,n)}. \tag{7.2.4}$$

The same argument as in the case $g=e$ applied to the semi-infinite cohomology or no-ghost theorem construction of $\mathfrak{m}_g$ yields natural isomorphisms

$$\mathfrak{m}_g^{(m/N,n)} \cong V_{g^{-m},n/N}^\natural(mn/N) \tag{7.2.5}$$

where $V_{g^{-m},n/N}^\natural$ is the subspace of $V_{g^{-m}}^\natural$ upon which g acts by $\mathrm{e}(n/N)$ and $V_{g^{-m},n/N}^\natural(mn/N)$ is the L_0-eigenspace of $V_{g^{-m},n/N}^\natural$ with eigenvalue $mn/N+1$.

Remark 7.2.2. Let us write V^Λ for the vertex operator algebra associated to the Leech lattice. In his paper [Tui95] Tuite gave strong evidence that the genus zero property of monstrous moonshine is equivalent to the following duality isomorphisms,

$$V_{g^m,n/N}^\natural \cong V_{g^n,m/N}^\natural, \tag{7.2.6}$$

$$V_{g^m,n/N}^\natural \cong V_{h^n,m/N}^\Lambda, \tag{7.2.7}$$

the first holding in the case that g is Fricke, and the second in the case that g is non-Fricke. In the second case we may take g to lie in a subgroup $2^{1+24}.\,Co_1$ of $\mathbb{M}$ and the h in (7.2.7) denotes an element of $2^{24}.2.\,Co_1$, a subgroup of $\mathrm{Aut}(V^\Lambda)$, such that h and g project to the same conjugacy class of Co_1. Thus the Tuite duality in the Fricke case implies the symmetry

$$\mathfrak{m}_g^{(m/N,n)} \cong \mathfrak{m}_g^{(n/N,m)} \tag{7.2.8}$$

of the monstrous Lie algebra $\mathfrak{m}_g$, as is known to hold in the case $g = e$ studied in [Bor92]. In the non-Fricke case the Tuite duality suggests an alternative construction of the VOA $W_g^\natural$ as

$$W_g^\natural = \bigoplus_{k=0}^{N-1} \left(V_{h^k}^\Lambda \otimes V_{\tilde{L}+(0,k)} \right)^{\langle h \rangle} \tag{7.2.9}$$

where $\tilde{L} = \frac{1}{N}\mathbb{Z} \times N\mathbb{Z}$.

We now re-scale the grading in $W_g^\natural$ and $\mathfrak{m}_g$ by interchanging $(m/N, n)$ with $(m, n/N)$, and we set

$$\mathfrak{m}_g^m = \bigoplus_{n \in \frac{1}{N}\mathbb{Z}} \mathfrak{m}_g^{(m,n/N)} \tag{7.2.10}$$

for $m \in \mathbb{Z}$. Then (7.2.5) implies isomorphisms of graded spaces

$$\mathfrak{m}_g^1 \cong V_{g^{-1}}^\natural, \quad \mathfrak{m}_g^{-1} \cong V_g^\natural, \tag{7.2.11}$$

and we also have

$$\mathfrak{m}_g^0 = \mathfrak{m}_g^{(0,0)} = \mathbb{C}c \oplus \mathbb{C}d, \tag{7.2.12}$$

where c and d are the degree operators for the re-scaled grading.

In [Car07] Carnahan shows that $\mathfrak{m}_g$ is a GKM algebra, thus generalizing a result of [Bor92]. When g is Fricke, $\mathfrak{m}_g$ has a structure very similar to that of the original Borcherds Monster Lie algebra $\mathfrak{m} = \mathfrak{m}_e$. In particular, it has one real simple root and all simple roots correspond to a basis for $V_g^\natural$. This implies that $\mathfrak{m}_g$ can be reconstructed from the subalgebra

$$\mathfrak{m}_g^1 \oplus \mathfrak{m}_g^0 \oplus \mathfrak{m}_g^{-1} \tag{7.2.13}$$

which is called the *local subalgebra of* $\mathfrak{m}_g$ (cf. [FF83]).

Remark 7.2.3. When g is non-Fricke $\mathfrak{m}_g$ does not have real simple roots, and in general it cannot be reconstructed from its local subalgebra (7.2.13). However the Tuite duality suggests that if one considers the second grading of $\mathfrak{m}_g$ then the local subalgebra consists of V_h^Λ and $V_{h^{-1}}^\Lambda$ and the h-twisted Heisenberg algebra. This local subalgebra is expected to generate $\mathfrak{m}_g$ in the case that g is non-Fricke.

In his thesis [Car07] Carnahan also obtained remarkable generalizations of the Borcherds identities for each of the monstrous Lie algebras $\mathfrak{m}_g$; viz.,

$$p(T_g(w) - J_g(z)) = \prod_{m\in\mathbb{Z}^+,n\in\mathbb{Z}} (1-p^m q^{n/N})^{c_{g^m,n/N}(mn/N)} \tag{7.2.14}$$

where we have set

$$c_{g^m,n/N}(mn/N) = \dim V^\natural_{g^m,n/N}(mn/N). \tag{7.2.15}$$

When g is Fricke the invariance of $T_g(w)$ under the Fricke involution and a re-scaling $w \mapsto Nw$ yields

$$p(J_g(Nw) - J_g(Nz)) = \prod_{m\in\mathbb{Z}^+,n\in\mathbb{Z}} (1-p^m q^n)^{c_{g^m,n/N}(mn/N)}. \tag{7.2.16}$$

Dividing both sides of (7.2.16) by $(1-pq^{-1})$ we obtain expressions which are invariant under the transposition of p with q. This entails the identity

$$c_{g^m,n/N}(mn/N) = c_{g^m,m/N}(mn/N) \tag{7.2.17}$$

which is in agreement with the Tuite duality of (7.2.6). The identity (7.2.14) implies an unexpected formula for the graded dimension of the Verma module with trivial character $\mathcal{V}_g$ associated to g.

$$\mathcal{V}_g = \mathcal{U}(\mathfrak{m}_g^-) \tag{7.2.18}$$

In fact the standard product formula

$$\operatorname{gdim} \mathcal{V}_g = \prod_{m\in\mathbb{Z}^+,n\in\mathbb{Z}} (1-p^m q^{n/N})^{-c_{g^m,n/N}(mn/N)} \tag{7.2.19}$$

for the graded dimension of $\mathcal{V}_g$ follows from (7.2.5) and (7.2.15). The identity (7.2.14) yields the alternative expression

$$\operatorname{gdim} \mathcal{V}_g = \frac{1}{p(T_g(w) - J_g(z))}. \tag{7.2.20}$$

This expression allows us to view the bi-graded dimension as a meromorphic function on $\mathbb{H}\times\mathbb{H}$.

Thanks to the properties of principal moduli for curves of genus zero, the expression (7.2.20) is singular at the point (w,z) precisely when $\Gamma_g \cdot w = \Gamma_g \cdot (-1/z)$. In §7.3 we will give an interpretation of this fact in the setting of three dimensional quantum gravity.

With the goal of making such an interpretation in mind we propose to rewrite the first expression (7.2.19) for the bi-graded dimension of the Verma module $\mathcal{V}_g$ as

$$\operatorname{gdim} \mathcal{V}_g = \exp\left(\sum_{m\in\mathbb{Z}^+} \hat{T}_g(m) J_g(z) p^m \right) \tag{7.2.21}$$

using generalized Hecke operators $\hat{T}_g(m)$ such as those discussed in §5.5; we have verified there the existence of such operators for $g = e$ and we conjecture that suitable $\hat{T}_g(m)$ exist for every $g \in \mathbb{M}$. Comparing then with the generating functions

$$Z_g(p,q) = \sum_{m\in\mathbb{Z}^+} m\hat{T}_g(m) J_g(z) p^m \tag{7.2.22}$$

of the higher order Rademacher sums $J_g^{(-m)}(z)$ we obtain the following expression.

$$Z_g(p,q) = p\partial_p \log(\operatorname{gdim} \mathcal{V}_g) \tag{7.2.23}$$

An identity of this form is well-known in the theory of symmetric functions (cf. [Mac95]), where it serves to relate the generating function of the power symmetric functions

$$p_n = \sum_{1\leq i} x_i^n \tag{7.2.24}$$

with that of the complete symmetric functions

$$h_n = \sum_{1\leq i_1 \leq \cdots \leq i_n} \prod_{k=1}^{n} x_{i_k}. \tag{7.2.25}$$

Thus the graded dimensions of the Verma modules $\mathcal{V}_g$ may be viewed as *complete Rademacher sums*, where the rôle of the variables x_i, for $i \in \mathbb{Z}^+$, in (7.2.24) and (7.2.25) is taken up by the exponential expressions $\mathrm{e}(\llbracket\gamma \cdot z')$ for $z' = -1/z$ and $\llbracket\gamma \in \llbracket\Gamma_g$.

Since all the coefficients appearing in the bi-graded dimension $Z_g(p,q)$ are non-negative integers, one may expect to naturally find a bi-graded vector space, and possibly even an $\mathfrak{m}_g$-module, with bi-graded dimension given by $Z_g(p,q)$. The next result suggests that one can expect to find such a space within $\mathcal{V}_g$.

Given two elements $F = \sum F_{m,n} p^m q^n$ and $G = \sum G_{m,n} p^m q^n$ in $\mathbb{Z}(\!(q)\!)[[p]]$, let us write $F \leq G$ in the case that $F_{m,n} \leq G_{m,n}$ for all $m,n \in \mathbb{Z}$.

Proposition 7.2.4. *Let $g \in \mathbb{M}$. If g is Fricke then we have $Z_g(p,q) \leq \operatorname{gdim} \mathcal{V}_g$.*

Proof. Dividing both sides of (7.2.16) by $(1-pq^{-1})$ we obtain

$$1 - \sum_{m,n\in\mathbb{Z}^+} c_{g,\frac{m+n-1}{N}}\left(\frac{m+n-1}{N}\right)p^m q^n = \prod_{m,n\in\mathbb{Z}^+}(1-p^m q^n)^{c_{g^m,n/N}(mn/N)}. \tag{7.2.26}$$

We denote the sum in the left hand side by Σ^+ and the product in the right hand side by Π^+. Then we have

$$Z_g(p,q) = -p\partial_p \log(1-pq^{-1})\Pi^+ = \frac{pq^{-1}}{1-pq^{-1}} + \frac{p\partial_p\Sigma^+}{1-\Sigma^+}. \tag{7.2.27}$$

On the other hand

$$\operatorname{gdim}\mathcal{V}_g = \frac{1}{1-pq^{-1}}\frac{1}{1-\Sigma^+} = \frac{1}{1-pq^{-1}} + \frac{\Sigma^+}{(1-pq^{-1})(1-\Sigma^+)}. \tag{7.2.28}$$

Thus it is sufficient to show that

$$p\partial_p(\Sigma^+) \leq \frac{1}{1-pq^{-1}}\Sigma^+, \tag{7.2.29}$$

but this follows from the observation that both sides of (7.2.29) have nonnegative coefficients and the left hand side may be obtained from the right hand side by deleting the terms which are singular or constant with respect to q. □

To formulate a conjecture on the nature of the subspaces of $\mathcal{V}_g$ with bi-graded dimensions $Z_g(p,q)$, as well as the origin of the higher order Rademacher sums, we turn again, in the next section, to the structures of twisted chiral 3d quantum gravity.

7.3 Second conjecture

We have shown in §5.5 that the higher order Rademacher sums recover the action of the Hecke operators on the first order Rademacher sums. In view of the conjectural relation between first order Rademacher sums and chiral 3d quantum gravities at central charge $c = 24$, we may consider an analogous interpretation for the higher order Rademacher sums given by $m(\hat{T}_g(m)J_g)(z)$ for $g \in \mathbb{M}$ and $m \in \mathbb{Z}^+$. Since all the Fourier coefficients of these expressions are non-negative integers, one might guess that there exist families of twisted chiral 3d quantum gravities for all central charges $c = 24m$, for $m \in \mathbb{Z}^+$. In particular, the untwisted ($g = e$) chiral 3d quantum gravities possess the structure of certain extremal vertex algebras with the Monster symmetry.

The aforementioned class of extremal vertex algebras, with the addition of a Virasoro element, has been originally conjectured by Witten [Wit07]. However, it was shown in [Gai08] and

[Hoe08] that the addition of a Virasoro element precludes a non-trivial action of the Monster group. The higher order Rademacher sums also point to the partition functions without elements of spin 2. We may modify Witten's conjecture by asking for the existence of extremal vertex algebras with partition functions given by the function $J^{(-m)}(z)$ for $m > 0$, related to the higher order Rademacher sums via $J^{(-m)}(z) = Q_{\Gamma}^{(-m)}(z) - \mathrm{c}_{\Gamma}(-m, 0)$, with $\Gamma = PSL_2(\mathbb{Z})$. The validity of this conjecture remains open.

Note that the Virasoro algebra, even when not represented by any actual state, may still act on a vertex algebra with partition function $J^{(-m)}(z)$. Regardless of whether or not spaces $V^{(-m)}$ with partition function $J^{(-m)}(z)$ admit natural vertex algebra structures, they certainly naturally inherit actions of the Monster group, since the actions of Hecke operators $m\hat{T}(m)$ on the Fourier coefficients of $J(z)$ may be interpreted as actions on representations of $\mathbb{M}$ (cf. [JLW95]).

It is natural to enquire as to the meaning of the spaces $V_g^{(-m)}$, for $m \in \mathbb{Z}^+$ and $g \in \mathbb{M}$, with graded dimension $J_g^{(-m)}(z)$. In light of our First Conjecture, it is unlikely that the spaces $V^{(-m)}$ can represent states of a three dimensional quantum gravity with $c = 24m$, since a Virasoro element is generally not present. Thus we have to conclude that the three dimensional quantum gravity $V^{(-1)} = V^{\natural}$ is the only viable candidate. Then one might view the spaces $V^{(-m)}$ for $m > 1$ as some higher overtones of the basic $m = 1$ theory.

In fact, we have shown in §5.5 that the action of the classical Hecke operator $\hat{T}(m)$ on the Rademacher sum (1.2.1) yields a sum over $\Gamma_\infty \backslash M(m)$, where $M(m)$ denotes the (image in $G(\mathbb{Q})$ of the) set of 2×2 matrices with integral entries and determinant m. This sum may be viewed as the *m-instanton correction* of the partition function in three dimensional quantum gravity. By *n-instanton* in this context one understands an elliptic curve which admits a holomorphic map of degree n into a given elliptic curve $E_{[\![z}$ (cf. [DMVV97]). Thus the sum over $\Gamma_\infty \backslash M(n)$ becomes a sum over all three dimensional hyperbolic structures on a solid torus with genus one boundary whose conformal structure corresponds to an n-instanton on $E_{[\![z}$. The same phenomena is expected for all the twisted 3d quantum gravities corresponding to elements $g \in \mathbb{M}$.

Collecting all the m-instanton contributions in one generating function we then obtain a partition function

$$Z_g(p,q) = \sum_{m \in \mathbb{Z}^+} m(\hat{T}_g(m)J_g)(z)p^m \tag{7.3.1}$$

depending on two variables, for each $g \in \mathbb{M}$. This partition function $Z_g(p,q)$ may be viewed as a part of the full partition function

$$\tilde{Z}_g(p,q) = \exp\left(\sum_{m \in \mathbb{Z}^+} (\hat{T}_g(m)J_g)(z)p^m\right) \tag{7.3.2}$$

of the stringy second quantization of $V_g^\natural$, introduced in [DMVV97] in the untwisted case $g = e$. (See also [Tui08].) We will now generalize their construction to an arbitrary twisted module $V_g^\natural$.

Let V be an arbitrary vertex operator algebra; in our case $V = V^\natural$. For n a positive integer, let $V^{\otimes n}$ denote the tensor product of n copies of V, and let Z_n be the group of cyclic permutations of the factors generated by an n-cycle $\sigma_n = (1, 2, \cdots, n)$. Let g be an automorphism of V of order N, then $g \times \sigma_n$ is an automorphism of $V^{\otimes n}$ of order nN/d where $d = (n, N)$. To the pair $(V^{\otimes n}, g \times \sigma_n)$ is canonically associated a twisted module (cf. [BDM02]), which we denote $V_{(g,n)}$. The group $Z_{g,n} = \langle g \times \sigma_n \rangle$ acts naturally on $V_{(g,n)}$. We write $V_{(g,n)}^{Z_{g,n}}$ for the $Z_{g,n}$-invariant subspace. The *stringy second quantization of the twisted module* V_g, to be denoted $\mathbb{S}\, V_g$, is, by definition, the space

$$\mathbb{S}\, V_g = \bigoplus_{\lambda \in \mathcal{P}} \bigotimes_{r>0} S^{m_r} V_{(g,r)}^{Z_{g,r}}, \tag{7.3.3}$$

where the sum is taken over all partitions λ with m_r parts of length $r > 0$. The space $\mathbb{S}\, V_g$ is doubly graded: by the degrees of products of twisted sectors and by the value of $|\lambda|$. For $g = e$ our definition of the stringy second quantization coincides with that of [DMVV97].

Next we establish a relation between the second quantization $\mathbb{S}\, V_g^\natural$ and the Verma module $\mathcal{V}_g$. First note the canonical isomorphism

$$\mathcal{U}(\mathfrak{m}_g^-) \cong S(\mathfrak{m}_g^-). \tag{7.3.4}$$

Then we obtain the following result.

Theorem 7.3.1. *There is a canonical isomorphism of bi-graded vector spaces*

$$\mathbb{S}\, V_g^\natural \cong S(\mathfrak{m}_g^-). \tag{7.3.5}$$

Proof. The isomorphism (7.3.5) follows from the existence of isomorphisms

$$(V_{(g,n)}^\natural)^{Z_{g,n}} \cong \mathfrak{m}_g^{-n} \tag{7.3.6}$$

of bi-graded vector spaces for each $n \in \mathbb{Z}^+$. To establish the existence of these we will use the isomorphism

$$V_{(g,n)}^\natural \cong V_{g^n}^\natural \tag{7.3.7}$$

of [BDM02].

We wish to show that the subspace of $V^\natural_{g^n}$ fixed by the operator

$$g \times \mathrm{e}((L_0 - 1)/n) \tag{7.3.8}$$

is naturally isomorphic to $\mathfrak{m}_g^n$. Consider the invariant subspace of $V^\natural_{g^n}$ with respect to the N-th power of the operator (7.3.8), which may be expressed as $\mathrm{e}((L_0 - 1)N/n)$. Its action on the graded subspace $V^\natural_{g^n}(kd/N)$ for $k \in \mathbb{Z}$ is multiplication by $\mathrm{e}(kd/n)$, and this scalar is 1 if and only if $k = (n/d)m$ for some $m \in \mathbb{Z}$. Thus we are only concerned with the graded subspaces $V^\natural_{g^n}(nm/N)$ where $m \in \mathbb{Z}$. To find the invariant subspaces with respect to the operator (7.3.8) we consider its action on the subspaces of the form $V^\natural_{g^n,m'/N}(mn/N)$. The action is scalar multiplication by $\mathrm{e}(-m'/N)\,\mathrm{e}(m/N)$ and is therefore trivial if and only if $m \equiv m' \pmod{N}$. Thus the full subspace of $V^\natural_{g^n}$ invariant under (7.3.8) is given by

$$\bigoplus_{m\in\mathbb{Z}} V^\natural_{g^n,m/N}(mn/N) \cong \mathfrak{m}_g^{-n}. \tag{7.3.9}$$

To complete the proof we note that the group generated by the action of the operator (7.3.8) has order nN/d, and under the isomorphism (7.3.7) its action recovers that of $Z_{g,n}$. □

The isomorphism of Theorem 7.3.1 suggests that the stringy second quantization $\mathbb{S}\,V^\natural_g$ admits an action by the Lie algebra $\mathfrak{m}_g$ and thus provides a Fock space realization of the Verma module $\mathcal{V}_g$. When $\mathfrak{m}_g$ is generated by its local subalgebra (7.2.13), as happens in the Fricke case, it is sufficient to describe the action of brackets $[\mathfrak{m}_g^{\pm 1}, \mathfrak{m}_g^{-n}] \subset \mathfrak{m}_g^{-n\pm 1}$ via the action of $V^\natural_{g^{\pm 1}}$ on the twisted sector for $((V^\natural)^{\otimes n}, g \times \sigma_n)$. Note also that the removal of the subspaces corresponding to the terms which are singular or constant with respect to q, as in the proof of Proposition 7.2.4, will yield an embedding of the instanton subspace $\mathcal{I}_g$ inside the stringy second quantization of $V^\natural_g$.

Our interpretation of the higher order Rademacher sums and the complete Rademacher sums, and their relation to the second quantization of the moonshine vertex operator algebra and its twisted modules, as well as the monstrous Lie algebras and their Verma modules, suggests the following extension of our first conjecture, Conjecture 7.1.1.

Conjecture 7.3.2. *Assuming the existence of a family of g-twisted chiral 3d quantum gravities for $g \in \mathbb{M}$, having the properties stated in Conjecture 7.1.1, there also exists a natural geometric interpretation of the family of twisted monstrous Lie algebras $\mathfrak{m}_g$, the instanton spaces $\mathcal{I}_g$, and the denominator formulas for all $g \in \mathbb{M}$ via the second quantization of the corresponding g-twisted chiral three 3d quantum gravities.*

First of all, the partition function of the second quantized g-twisted chiral 3d quantum gravity should depend on two modular parameters w and z, and should respect the symmetry that interchanges w with $-1/z$. Second, there should be a quantum gravity theoretic explanation for why these partition functions are singular precisely when w and $-1/z$ belong to the same orbit of Γ_g. This will explain the remarkable denominator formulas (7.2.14) of Carnahan, and ultimately, the fundamental rôle of the principal moduli in the moonshine Conjectures.

Where can we find an appropriate setting for all the structures that appear in our Second Conjecture? The first answer that might come to mind is the 26 dimensional bosonic string theory. It was known for a long time that the physical space has a Lie algebra structure (cf. [Fre85], [GO85]), which can also be recovered from the semi-infinite cohomology (cf. [FGZ86], [LZ95]). However, in this way one can only get a fake Monster Lie algebra (cf. [Bor92]) and there is no (straight forward) geometric way to turn it into the real Monster Lie algebra that appears in the three dimensional quantum gravity approach. Also, the 26 dimensions of the bosonic string have nothing to do with the 3 dimensions of the quantum gravity. It is still possible that some constructions of string theory can be applied in the 3d quantum gravity setting. In particular, one can expect to identify the negative part $\mathfrak{m}^-$ of the Monster Lie algebra in the space of the second quantization of $V^\natural$ with a certain version of BPS states (cf. [HM96]).

Clearly, our results on Rademacher sums, their relation to the moonshine module, monstrous Lie algebras, and 3d quantum gravity, admit a super-counterpart [DF09]. In this case the promise of relationships with the structures of the 10 dimensional superstring is even more tempting, since the latter has played such a prominent rôle in physics over the past 25 years. However, in spite of the of the remarkable mathematical similarity, the 10 of the ten dimensional superstring and the 3 of the 3d quantum supergravity emerging from the super-counterpart of the Rademacher sums have different geometric meaning and are not related by a compactification of any kind.

The most fascinating fact about the 3d quantum supergravity is that while it is similar, but not directly related, to the initial 3d quantum gravity, the corresponding second quantized theories are directly related. The higher order Rademacher sums point to a larger second quantized space in the super-case; a space which contains the second quantized space we considered above.

Then what can these second quantized 3d quantum gravities mean in physics? Naïvely, any quantization can be interpreted as a categorification, which lifts a given theory one dimension up. One can then wonder if the second quantization in our case might point to an extreme sector of certain four dimensional quantum gravities, such as the extreme Kerr black hole, which was recently found in [GHSS08] also to be dual to a chiral 2d CFT. In this case the Monster (or moonshine) might be the answer to the perpetual question of what is behind the letter M in the theory that has not yet revealed its true name.

Abstract: The current status of 'Mathieu Moonshine', the idea that the Mathieu group $\mathbb{M}_{24}$ organises the elliptic genus of K3, is reviewed. While there is a consistent decomposition of all Fourier coefficients of the elliptic genus in terms of Mathieu $\mathbb{M}_{24}$ representations, a conceptual understanding of this phenomenon in terms of K3 sigma-models is still missing. In particular, it follows from the recent classification of the automorphism groups of arbitrary K3 sigma-models that (i) there is no single K3 sigma-model that has $\mathbb{M}_{24}$ as an automorphism group; and (ii) there exist 'exceptional' K3 sigma-models whose automorphism group is not even a subgroup of $\mathbb{M}_{24}$. Here we show that all cyclic torus orbifolds are exceptional in this sense, and that almost all of the exceptional cases are realised as cyclic torus orbifolds. We also provide an explicit construction of a $\mathbb{Z}_5$ torus orbifold that realises one exceptional class of K3 sigma-models.

1 Introduction

In 2010, Eguchi, Ooguri and Tachikawa observed that the elliptic genus of K3 shows signs of an underlying Mathieu $\mathbb{M}_{24}$ group action [1]. In particular, they noted (see section 2 below for more details) that the Fourier coefficients of the elliptic genus can be written as sums of dimensions of irreducible $\mathbb{M}_{24}$ representations.[†] This intriguing observation is very reminiscent of the famous realisation of McKay and Thompson who noted that the Fourier expansion coefficients of the J-function can be written in terms of dimensions of representations of the Monster group [2, 3]. This led to a development that is now usually referred to as 'Monstrous Moonshine', see [4] for a nice review. One important upshot of that analysis was that the J-function can be thought of as the partition function of a self-dual conformal field theory, the 'Monster conformal field theory' [5, 6], whose automorphism group is precisely the Monster group. The existence of this conformal field theory explains many aspects of Monstrous Moonshine although not all — in particular, the genus zero property is rather mysterious from this point of view.

---

[*] Partially based on talk given by M.R.G. at the conference 'Conformal Field Theory, Automorphic Forms and Related Topics', Heidelberg, 19-23 September 2011.

[†] Actually, they did not just look at the Fourier coefficients themselves, but at the decomposition of the elliptic genus with respect to the elliptic genera of irreducible $\mathcal{N} = 4$ superconformal representations. They then noted that these expansion coefficients (and hence in particular the usual Fourier coefficients) are sums of dimensions of irreducible $\mathbb{M}_{24}$ representations.

In the Mathieu case, the situation is somewhat different compared to the early days of Monstrous Moonshine. It is by construction clear that the underlying conformal field theory *is* a K3 sigma-model (describing string propagation on the target space K3). However, this does not characterise the corresponding conformal field theory uniquely as there are many inequivalent such sigma-models — in fact, there is an 80-dimensional moduli space of such theories, all of which lead to the same elliptic genus. The natural analogue of the 'Monster conformal field theory' would therefore be a special K3 sigma-model whose automorphism group coincides with $\mathbb{M}_{24}$. Unfortunately, as we shall review here (see section 3), such a sigma-model does not exist: we have classified the automorphism groups of all K3 sigma-models, and none of them contains $\mathbb{M}_{24}$ [7]. In fact, not even all automorphism groups are contained in $\mathbb{M}_{24}$: the exceptional cases are the possibilities (ii), (iii) and (iv) of the theorem in section 3 (see [7]), as well as case (i) for nontrivial G'. Case (iii) was already shown in [7] to be realised by a specific Gepner model that is believed to be equivalent to a torus orbifold by $\mathbb{Z}_3$. Here we show that also cases (ii) and (iv) are realised by actual K3s — the argument in [7] for this relied on some assumption about the regularity of K3 sigma-models — and in both cases the relevant K3s are again torus orbifolds. More specifically, case (ii) is realised by an asymmetric $\mathbb{Z}_5$ orbifold of $\mathbb{T}^4$ (see section 5),[‡] while for case (iii) the relevant orbifold is by $\mathbb{Z}_3$ (see section 6).

Cyclic torus orbifolds are rather special K3s since they always possess a quantum symmetry whose orbifold leads back to $\mathbb{T}^4$. Using this property of cyclic torus orbifolds, we show (see section 4) that the group of automorphisms of K3s that are cyclic torus orbifolds is always exceptional; in particular, the quantum symmetry itself is never an element of $\mathbb{M}_{24}$. Although some 'exceptional' automorphism groups (contained in case (i) of the classification theorem) can also arise in K3 models that are not cyclic torus orbifolds, our observation may go a certain way towards explaining why only $\mathbb{M}_{24}$ seems to appear in the elliptic genus of K3.

We should mention that Mathieu Moonshine can also be formulated in terms of a mock modular form that can be naturally associated to the elliptic genus of K3 [1, 9, 10, 11]; this point of view has recently led to an interesting class of generalisations [12]. There are also indications that, just as for Monstrous Moonshine, Mathieu Moonshine can possibly be understood in terms of an underlying Borcherds-Kac-Moody algebra [13, 14, 15, 16].

2 Mathieu Moonshine

Let us first review the basic idea of 'Mathieu Moonshine'. We consider a conformal field theory sigma-model with target space K3. This theory has $\mathcal{N} = (4, 4)$ superconformal symmetry on the world-sheet. As a consequence, the space of states can be decomposed into representations of the $\mathcal{N} = 4$ superconformal algebra, both for the left- and the right-movers. (The left- and right-moving actions commute, and thus we can find a simultaneous decomposition.) The full space of states takes then the form

---

[‡] Since the orbifold action is asymmetric, this evades various no-go-theorems (see e.g. [8]) that state that the possible orbifold groups are either $\mathbb{Z}_2$, $\mathbb{Z}_3$, $\mathbb{Z}_4$, or $\mathbb{Z}_6$.

$$\mathcal{H} = \bigoplus_{i,j} N_{ij}\, \mathcal{H}_i \otimes \bar{\mathcal{H}}_j \ , \tag{2.1}$$

where i and j label the different $\mathcal{N} = 4$ superconformal representations, and $N_{ij} \in \mathbb{N}_0$ denote the multiplicities with which these representations appear. The $\mathcal{N} = 4$ algebra contains, apart from the Virasoro algebra L_n at $c = 6$, four supercharge generators, as well as an affine $\hat{\mathfrak{su}}(2)_1$ subalgebra at level one; we denote the Cartan generator of the zero mode subalgebra $\mathfrak{su}(2)$ by J_0.

The full partition function of the conformal field theory is quite complicated, and is only explicitly known at special points in the moduli space. However, there exists some sort of partial index that is much better behaved. This is the so-called *elliptic genus* that is defined by

$$\phi_{\rm K3}(\tau, z) = \mathrm{Tr}_{\rm RR}\Big(q^{L_0-\frac{c}{24}}\, y^{J_0}\, (-1)^F\, \bar{q}^{\bar{L}_0-\frac{\bar{c}}{24}}\, (-1)^{\bar{F}}\Big) \equiv \phi_{0,1}(\tau, z) \ . \tag{2.2}$$

Here the trace is only taken over the Ramond-Ramond part of the spectrum (2.1), and the right-moving $\mathcal{N} = 4$ modes are denoted by a bar. Furthermore, $q = \exp(2\pi i\tau)$ and $y = \exp(2\pi i z)$, F and $\bar{F}$ are the left- and right-moving fermion number operators, and the two central charges equal $c = \bar{c} = 6$. Note that the elliptic genus does not actually depend on $\bar{\tau}$, although $\bar{q} = \exp(-2\pi i\bar{\tau})$ does; the reason for this is that, with respect to the right-moving algebra, the elliptic genus is like a Witten index, and only the right-moving ground states contribute. To see this one notices that states that are not annihilated by a supercharge zero mode appear always as a boson-fermion pair; the contribution of such a pair to the elliptic genus however vanishes because the two states contribute with the opposite sign (as a consequence of the $(-1)^{\bar{F}}$ factor). Thus only the right-moving ground states, i.e. the states that are annihilated by all right-moving supercharge zero modes, contribute to the elliptic genus, and the commutation relations of the $\mathcal{N} = 4$ algebra then imply that they satisfy $(\bar{L}_0 - \frac{\bar{c}}{24})\phi_{\rm ground} = 0$; thus it follows that the elliptic genus is independent of $\bar{\tau}$. Note that this argument does not apply to the left-moving contributions because of the y^{J_0} factor. (The supercharges are 'charged' with respect to the J_0 Cartan generator, and hence the two terms of a boson-fermion pair come with different powers of y. However, if we also set $y = 1$, the elliptic genus does indeed become a constant, independent of τ and $\bar{\tau}$.)

It follows from general string considerations that the elliptic genus defines a *weak Jacobi form of weight zero and index one* [17]. Recall that a weak Jacobi form of weight w and index m is a function [18]

$$\phi_{w,m} : \mathbb{H}_+ \times \mathbb{C} \to \mathbb{C} \ , \qquad (\tau, z) \mapsto \phi_{w,m}(\tau, z) \tag{2.3}$$

that satisfies

$$\phi_{w,m}\Big(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\Big) = (c\tau + d)^w\, e^{2\pi i m \frac{cz^2}{c\tau+d}}\, \phi_{w,m}(\tau, z) \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbb{Z}) \ , \tag{2.4}$$

$$\phi(\tau, z + \ell\tau + \ell') = e^{-2\pi i m(\ell^2\tau + 2\ell z)}\phi(\tau, z) \qquad\qquad \ell, \ell' \in \mathbb{Z} \ , \tag{2.5}$$

and has a Fourier expansion

$$\phi(\tau,z) = \sum_{n\geq 0,\, \ell\in\mathbb{Z}} c(n,\ell) q^n y^\ell \tag{2.6}$$

with $c(n,\ell) = (-1)^w c(n,-\ell)$. Weak Jacobi forms have been classified, and there is only one weak Jacobi form with $w=0$ and $m=1$. Up to normalisation $\phi_{\rm K3}$ must therefore agree with this unique weak Jacobi form $\phi_{0,1}$, which can explicitly be written in terms of Jacobi theta functions as

$$\phi_{0,1}(\tau,z) = 8 \sum_{i=2,3,4} \frac{\vartheta_i(\tau,z)^2}{\vartheta_i(\tau,0)^2} \ . \tag{2.7}$$

Note that the Fourier coefficients of $\phi_{\rm K3}$ are integers; as a consequence they cannot change continuously as one moves around in the moduli space of K3 sigma-models, and thus $\phi_{\rm K3}$ must be actually independent of the specific K3 sigma-model that is being considered, i.e. independent of the point in the moduli space. Here we have used that the moduli space is connected. More concretely, it can be described as the double quotient

$$\mathcal{M}_{\rm K3} = {\rm O}(\Gamma^{4,20}) \setminus {\rm O}(4,20) \ / \ {\rm O}(4)\times {\rm O}(20) \ . \tag{2.8}$$

We can think of the Grassmannian on the right

$${\rm O}(4,20) \ / \ {\rm O}(4)\times {\rm O}(20) \tag{2.9}$$

as describing the choice of a positive-definite 4-dimensional subspace $\Pi \subset \mathbb{R}^{4,20}$, while the group on the left, ${\rm O}(\Gamma^{4,20})$, leads to discrete identifications among them. Here ${\rm O}(\Gamma^{4,20})$ is the group of isometries of a given fixed unimodular lattice $\Gamma^{4,20} \subset \mathbb{R}^{4,20}$. (In physics terms, the lattice $\Gamma^{4,20}$ can be thought of as the D-brane charge lattice of string theory on K3.)

Let us denote by $\mathcal{H}^{(0)} \subset \mathcal{H}_{\rm RR}$ the subspace of (2.1) that consists of those RR states for which the right-moving states are ground states. (Thus $\mathcal{H}^{(0)}$ consists of the states that contribute to the elliptic genus.) $\mathcal{H}^{(0)}$ carries an action of the left-moving $\mathcal{N}=4$ superconformal algebra, and at any point in moduli space, its decomposition is of the form

$$\mathcal{H}^{(0)} = 20\cdot \mathcal{H}_{h=\frac{1}{4},j=0} \ \oplus \ 2\cdot \mathcal{H}_{h=\frac{1}{4},j=\frac{1}{2}} \ \oplus \ \bigoplus_{n=1}^{\infty} D_n\, \mathcal{H}_{h=\frac{1}{4}+n,j=\frac{1}{2}} \ , \tag{2.10}$$

where $\mathcal{H}_{h,j}$ denotes the irreducible $\mathcal{N}=4$ representation whose Virasoro primary states have conformal dimension h and transform in the spin j representation of $\mathfrak{su}(2)$. The multiplicities D_n are *not* constant over the moduli space, but the above argument shows that

$$A_n = {\rm Tr}_{D_n}(-1)^{\bar F} \tag{2.11}$$

are (where D_n is now understood not just as a multiplicity, but as a representation of the right-moving $(-1)^{\bar F}$ operator that determines the sign with which these states contribute to the elliptic genus). In this language, the elliptic genus then takes the form

$$\phi_{\rm K3}(\tau,z) = 20\cdot \chi_{h=\frac{1}{4},j=0}(\tau,z) - 2\cdot \chi_{h=\frac{1}{4},j=\frac{1}{2}}(\tau,z) + \sum_{n=1}^{\infty} A_n \cdot \chi_{h=\frac{1}{4}+n,j=\frac{1}{2}}(\tau,z) \ , \tag{2.12}$$

where $\chi_{h,j}(\tau,z)$ is the 'elliptic' genus of the corresponding $\mathcal{N}=4$ representation,

$$\chi_{h,j}(\tau,z) = \mathrm{Tr}_{\mathcal{H}_{h,j}}\Big(q^{L_0-\frac{c}{24}}\, y^{J_0}(-1)^F\Big) \ , \tag{2.13}$$

and we have used that $(-1)^{\bar{F}}$ takes the eigenvalues $+1$ and -1 on the 20- and 2-dimensional multiplicity spaces of the first two terms in (2.10), respectively.

The key observation of Eguchi, Ooguri & Tachikawa (EOT) [1] was that the A_n are sums of dimensions of $\mathbb{M}_{24}$ representation, in striking analogy to the original Monstrous Moonshine conjecture of [3]; the first few terms are

$$\begin{aligned} A_1 &= 90 = \mathbf{45} + \overline{\mathbf{45}} && (2.14)\\ A_2 &= 462 = \mathbf{231} + \overline{\mathbf{231}} && (2.15)\\ A_3 &= 1540 = \mathbf{770} + \overline{\mathbf{770}} \ , && (2.16) \end{aligned}$$

where $\mathbf{N}$ denotes a representation of $\mathbb{M}_{24}$ of dimension N. Actually, they guessed correctly the first six coefficients; from A_7 onwards the guesses become much more ambiguous (since the dimensions of the $\mathbb{M}_{24}$ representations are not that large) and they actually misidentified the seventh coefficient in their original analysis. (We will come back to the question of why and how one can be certain about the 'correct' decomposition shortly, see section 2.2.) The alert reader will also notice that the first two coefficients in (2.10), namely 20 and -2, are not directly $\mathbb{M}_{24}$ representations; the correct prescription is to introduce virtual representations and to write

$$20 = \mathbf{23} - 3\cdot\mathbf{1} \ , \qquad -2 = -2\cdot\mathbf{1} \ . \tag{2.17}$$

Recall that $\mathbb{M}_{24}$ is a sporadic finite simple group of order

$$|\mathbb{M}_{24}| = 2^{10}\cdot 3^3\cdot 5\cdot 7\cdot 11\cdot 23 = 244\,823\,040 \ . \tag{2.18}$$

It has 26 conjugacy classes (which are denoted by 1A, 2A, 3A, …, 23A, 23B, where the number refers to the order of the corresponding group element) — see eqs. (2.19) and (2.20) below for the full list — and therefore also 26 irreducible representations whose dimensions range from $N=1$ to $N=10395$. The Mathieu group $\mathbb{M}_{24}$ can be defined as the subgroup of the permutation group S_{24} that leaves the extended Golay code invariant; equivalently, it is the quotient of the automorphism group of the $\mathfrak{su}(2)^{24}$ Niemeier lattice, divided by the Weyl group. Thought of as a subgroup of $\mathbb{M}_{24}\subset S_{24}$, it contains the subgroup $\mathbb{M}_{23}$ that is characterised by the condition that it leaves a given (fixed) element of $\{1,\ldots,24\}$ invariant.

2.1 Classical symmetries

The appearance of a Mathieu group in the elliptic genus of K3 is not totally surprising in view of the Mukai theorem [19, 20]. It states that any finite group of symplectic automorphisms of a K3 surface can be embedded into the Mathieu group $\mathbb{M}_{23}$. The symplectic automorphisms of a K3 surface define symmetries that act on the multiplicity spaces of the $\mathcal{N}=4$ representations, and therefore explain part of the above findings. However, it is also clear from Mukai's argument that they do not even account for the full $\mathbb{M}_{23}$ group. Indeed, every symplectomorphism of K3 has at least five orbits on the set $\{1,\ldots,24\}$, and thus not all elements of $\mathbb{M}_{23}$ can be realised as a symplectomorphism. More specifically, of the 26 conjugacy classes of $\mathbb{M}_{24}$, 16 have a representative in $\mathbb{M}_{23}$, namely

$$\text{repr. in } \mathbb{M}_{23}: \quad \begin{array}{ll} \text{1A, 2A, 3A, 4B, 5A, 6A, 7A, 7B, 8A} & \text{(geometric)} \\ \text{11A, 14A, 14B, 15A, 15B, 23A, 23B} & \text{(non-geometric)}\ , \end{array} \tag{2.19}$$

where 'geometric' means that a representative can be (and in fact is) realised by a geometric symplectomorphism (i.e. that the representative has at least five orbits when acting on the set $\{1,\ldots,24\}$), while 'non-geometric' means that this is not the case. The remaining conjugacy classes do *not* have a representative in $\mathbb{M}_{23}$, and are therefore not accounted for geometrically via the Mukai theorem

$$\text{no repr. in } \mathbb{M}_{23}: \quad \text{2B, 3B, 4A, 4C, 6B, 10A, 12A, 12B, 21A, 21B}\ . \tag{2.20}$$

The classical symmetries can therefore only explain the symmetries in the first line of (2.19). Thus an additional argument is needed in order to understand the origin of the other symmetries; we shall come back to this in section 3.

2.2 Evidence for Moonshine

As was already alluded to above, in order to determine the 'correct' decomposition of the A_n multiplicity spaces in terms of $\mathbb{M}_{24}$ representations, we need to study more than just the usual elliptic genus. By analogy with Monstrous Moonshine, the natural objects to consider are the analogues of the McKay Thompson series [21]. These are obtained from the elliptic genus upon replacing

$$A_n = \dim R_n \ \rightarrow\ \mathrm{Tr}_{R_n}(g)\ , \tag{2.21}$$

where $g \in \mathbb{M}_{24}$, and R_n is the $\mathbb{M}_{24}$ representation whose dimension equals the coefficient A_n; the resulting functions are then (compare (2.12))

$$\phi_g(\tau,z) = \mathrm{Tr}_{\mathbf{23}-3\cdot\mathbf{1}}(g)\,\chi_{h=\frac{1}{4},j=0}(\tau,z) - 2\,\mathrm{Tr}_{\mathbf{1}}(g)\,\chi_{h=\frac{1}{4},j=\frac{1}{2}}(\tau,z) + \sum_{n=1}^{\infty} \mathrm{Tr}_{R_n}(g)\,\chi_{h=\frac{1}{4}+n,j=\frac{1}{2}}(\tau,z)\ . \tag{2.22}$$

The motivation for this definition comes from the observation that if the underlying vector space $\mathcal{H}^{(0)}$, see eq. (2.10), of states contributing to the elliptic genus were to carry an action of $\mathbb{M}_{24}$, $\phi_g(\tau,z)$ would equal the 'twining elliptic genus', i.e. the elliptic genus twined by the action of g

$$\phi_g(\tau,z) = \mathrm{Tr}_{\mathcal{H}^{(0)}}\Big(g\, q^{L_0-\frac{c}{24}}\, y^{J_0}\, (-1)^F\, \bar{q}^{\bar{L}_0-\frac{\bar{c}}{24}}\, (-1)^{\bar{F}}\Big)\ . \tag{2.23}$$

Obviously, a priori, it is not clear what the relevant R_n in (2.21) are. However, we have some partial information about them:

(i) For any explicit realisation of a symmetry of a K3 sigma-model, we can calculate (2.23) directly. (In particular, for some symmetries, the relevant twining genera had already been calculated in [22].)

(ii) The observation of EOT determines the first six coefficients explicitly.

(iii) The twining genera must have special modular properties.

Let us elaborate on (iii). Assuming that the functions $\phi_g(\tau, z)$ have indeed an interpretation as in (2.23), they correspond in the usual orbifold notation of string theory to the contribution

$$\phi_g(\tau, z) \;\longleftrightarrow\; e\ \underset{g}{\boxed{}} \tag{2.24}$$

where e is the identity element of the group. Under a modular transformation it is believed that these twining and twisted genera transform (up to a possible phase) as

$$h\ \underset{g}{\boxed{}} \quad \xrightarrow{\begin{pmatrix} a & b \\ c & d \end{pmatrix}} \quad h^d g^c\ \underset{g^a h^b}{\boxed{}} \tag{2.25}$$

The twining genera (2.24) are therefore invariant (possibly up to a phase) under the modular transformations with

$$\gcd(a, o(g)) = 1 \qquad \text{and} \qquad c = 0 \mod o(g), \tag{2.26}$$

where $o(g)$ is the order of the group element g and we used that for $\gcd(a, o(g)) = 1$, the group element g^a is in the same conjugacy class as g or g^{-1}. (Because of reality, the twining genus of g and g^{-1} should be the same.) Since $ad - bc = 1$, the second condition implies the first, and we thus conclude that $\phi_g(\tau, z)$ should be (up to a possible multiplier system) a weak Jacobi form of weight zero and index one under the subgroup of $\mathrm{SL}(2, \mathbb{Z})$

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbb{Z}) \ : \ c = 0 \bmod (N) \right\} , \tag{2.27}$$

where $N = o(g)$. This is a relatively strong condition, and knowing the first few terms (for a fixed multiplier system) determines the function uniquely. In order to use this constraint, however, it is important to know the multiplier system. An ansatz (that seems to work, see below) was made in [23]

$$\phi_g\Big(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\Big) = e^{\frac{2\pi i c d}{N h}}\, e^{\frac{2\pi i\, c z^2}{c\tau + d}}\, \phi_g(\tau, z) \ , \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N) \ , \tag{2.28}$$

where N is again the order of g and $h | \gcd(N, 12)$. The multiplier system is trivial ($h = 1$) if and only if g contains a representative in $\mathbb{M}_{23} \subset \mathbb{M}_{24}$. For the other conjugacy classes, the values are tabulated in table 1. It was noted in [10] that h equals the length of the shortest cycle (when interpreted as a permutation in S_{24}, see table 1 of [10]).

Using this ansatz, explicit expressions for all twining genera were determined in [23]; independently, the same twining genera were also found (using guesses based on the cycle shapes of the corresponding S_{24} representations) in [24]. (Earlier partial results had been obtained in [9] and [25].)

Class	2B	3B	4A	4C	6B	10A	12A	12B	21AB
h	2	3	2	4	6	2	2	12	3

Table 1: Value of h for the conjugacy classes in (2.28).

These explicit expressions for the twining genera then allow for a very non-trivial check of the EOT proposal. As is clear from their definition in (2.22), they determine the coefficients

$$\mathrm{Tr}_{R_n}(g) \qquad \text{for all } g \in \mathbb{M}_{24} \text{ and all } n \geq 1. \tag{2.29}$$

This information is therefore sufficient to *determine* the representations R_n, i.e. to calculate their decomposition into irreducible $\mathbb{M}_{24}$ representations, for all n. We have worked out the decompositions explicitly for the first 500 coefficients, and we have found that each R_n can be written as a direct sum of $\mathbb{M}_{24}$ representations with non-negative integer multiplicities [23]. (Subsequently [24] tested this property for the first 600 coefficients, and apparently Tachikawa has also checked it for the first 1000 coefficients.) Terry Gannon has informed us that this information is sufficient to prove that the same will then happen for all n [26]. In some sense this then proves the EOT conjecture.

3 Symmetries of K3 models

While the above considerations establish in some sense the EOT conjecture, they do not offer any insight into why the elliptic genus of K3 should exhibit an $\mathbb{M}_{24}$ symmetry. This is somewhat similar to the original situation in Monstrous Moonshine, after Conway and Norton had found the various Hauptmodules by somewhat similar techniques. Obviously, in the case of Monstrous Moonshine, many of these observations were subsequently explained by the construction of the Monster CFT (that possesses the Monster group as its automorphism group) [5, 6]. So we should similarly ask for a microscopic explanation of these findings.

In some sense it is clear what the analogue of the Monster CFT in the current context should be: we know that the function in question *is* the elliptic genus of K3. However, there is one problem with this. As we mentioned before, there is not just one K3 sigma-model, but rather a whole moduli space (see eq. (2.8)) of such CFTs. So the simplest explanation of the EOT observation would be if there is (at least) one special K3 sigma-model that has $\mathbb{M}_{24}$ as its automorphism group. Actually, the relevant symmetry group should commute with the action of the $\mathcal{N} = (4,4)$ superconformal symmetry (since it should act on the multiplicity spaces in $\mathcal{H}^{(0)}$, see eq. (2.10)). Furthermore, since the two $\mathcal{N} = 4$ representations with $h = \frac{1}{4}$ and $j = \frac{1}{2}$ are singlets — recall that the coefficient -2 transforms as $-2 = -2 \cdot \mathbf{1}$, see (2.17) — the automorphism must act trivially on the 4 RR ground states that transform in the $(\mathbf{2},\mathbf{2})$ representation of the $\mathfrak{su}(2)_L \times \mathfrak{su}(2)_R$ subalgebra of $\mathcal{N} = (4,4)$. Note that these four states generate the simultaneous half-unit spectral flows in the left- and the right-moving sector; the requirement that the symmetry leaves them invariant therefore means that spacetime supersymmetry is preserved.

Recall from (2.8) that the different K3 sigma-models are parametrised by the choice of a positive-definite 4-dimensional subspace $\Pi \subset \mathbb{R}^{4,20}$, modulo some discrete identifications. Let us denote by G_Π the group of symmetries of the sigma-model described by Π that commute with the action of $\mathcal{N} = (4,4)$ and preserve the RR ground states in the $(\mathbf{2},\mathbf{2})$ (see above). It was argued in [7] that G_Π is precisely the subgroup of $\mathrm{O}(\Gamma^{4,20})$ consisting of those elements that leave Π pointwised fixed. The possible symmetry groups G_Π can then be classified following essentially the paradigm of the Mukai-Kondo argument for the symplectomorphisms of K3 surfaces [19, 20]. The outcome of the analysis can be summarised by the following theorem [7]:

Theorem: *Let G be the group of symmetries of a non-linear sigma-model on $K3$ preserving the $\mathcal{N} = (4,4)$ superconformal algebra as well as the spectral flow operators. One of the following possibilities holds:*

(i) $G = G'.G''$, *where G' is a subgroup of $\mathbb{Z}_2^{11}$, and G'' is a subgroup of $\mathbb{M}_{24}$ with at least four orbits when acting as a permutation on* $\{1,\ldots,24\}$

(ii) $G = 5^{1+2} : \mathbb{Z}_4$

(iii) $G = \mathbb{Z}_3^4 : A_6$

(iv) $G = 3^{1+4} : \mathbb{Z}_2.G''$, *where G'' is either trivial, $\mathbb{Z}_2$ or $\mathbb{Z}_2^2$.*

Here $G = N.Q$ means that N is a normal subgroup of G, and $G/N \cong Q$; when G is the semidirect product of N and Q, we denote it by $N : Q$. Furthermore, p^{1+2n} is an extra-special group of order p^{1+2n}, which is an extension of $\mathbb{Z}_p^{2n}$ by a central element of order p.

We will give a sketch of the proof below (see section 3.1), but for the moment let us comment on the implications of this result. First of all, our initial expectation from above is not realised: none of these groups $G \equiv G_\Pi$ contains $\mathbb{M}_{24}$. In particular, the twining genera for the conjugacy classes 12B, 21A, 21B, 23A, 23B of $\mathbb{M}_{24}$ cannot be realised by any symmetry of a K3 sigma-model. Thus we cannot give a direct explanation of the EOT observation along these lines.

Given that the elliptic genus is constant over the moduli space, one may then hope that we can explain the origin of $\mathbb{M}_{24}$ by 'combining' symmetries from different points in the moduli space. As we have mentioned before, this is also similar to what happens for the geometric symplectomorphisms of K3: it follows from the Mukai theorem that the Mathieu group $\mathbb{M}_{23}$ is the smallest group that contains all symplectomorphisms, but there is no K3 surface where all of $\mathbb{M}_{23}$ is realised, and indeed, certain generators of $\mathbb{M}_{23}$ can never be symmetries, see (2.19). However, also this explanation of the EOT observation is somewhat problematic: as is clear from the above theorem, not all symmetry groups of K3 sigma-models are in fact subgroups of $\mathbb{M}_{24}$. In particular, none of the cases (ii), (iii) and (iv) (as well as case (i) with G' non-trivial) have this property, as can be easily seen by comparing the prime factor decompositions of their orders to (2.18). The smallest group that contains all groups of the theorem is the Conway group Co_1, but as far as we are aware, there is no evidence of any 'Conway Moonshine' in the elliptic genus of K3.

One might speculate that, generically, the group G must be a subgroup of $\mathbb{M}_{24}$, and that the models whose symmetry group is not contained in $\mathbb{M}_{24}$ are, in some sense, special or 'exceptional' points in the moduli space. In order to make this idea precise, it is useful to analyse the exceptional models in detail. In [7], some examples have been provided of case (i) with non-trivial G' (a torus orbifold $\mathbb{T}^4/\mathbb{Z}_2$ or the Gepner model 2^4, believed to be equivalent to a $\mathbb{T}^4/\mathbb{Z}_4$ orbifold), and of case (iii) (the Gepner model 1^6, which is believed to be equivalent to a $\mathbb{T}^4/\mathbb{Z}_3$ orbifold, see also [27]). For the cases (ii) and (iv), only an existence proof was given. In section 5, we will improve the situation by constructing in detail an example of case (ii), realised as an asymmetric $\mathbb{Z}_5$-orbifold of a torus $\mathbb{T}^4$. Furthermore, in section 6 we will briefly discuss the $\mathbb{Z}_3$-orbifold of a torus and the explicit realisation of its symmetry group, corresponding to cases (ii) and (iv) for any G''.

Notice that all the examples of exceptional models known so far are provided by torus orbifolds. In fact, we will show below (see section 4) that all cyclic torus orbifolds have exceptional symmetry groups. Conversely, we will prove that the cases (ii)–(iv) of the theorem are always realised by (cyclic) torus orbifolds. On the other hand, as we shall also explain, some of the exceptional models in case (i) are not cyclic torus orbifolds.

3.1 Sketch of the proof of the Theorem

In this subsection, we will describe the main steps in the proof of the above theorem; the details can be found in [7].

It was argued in [7] that the supersymmetry preserving automorphisms of the non-linear sigma-model characterised by Π generate the group $G \equiv G_\Pi$ that consists of those elements of $O(\Gamma^{4,20})$ that leave Π pointwise fixed. Let us denote by L^G the sublattice of G-invariant vectors of $L \equiv \Gamma^{4,20}$, and define L_G to be its orthogonal complement that carries a genuine action of G. Since $L^G \otimes \mathbb{R}$ contains the subspace Π, it follows that L^G has signature $(4, d)$ for some $d \geq 0$, so that L_G is a negative-definite lattice of rank $20 - d$. In [7], it is proved that, for any consistent model, L_G can be embedded (up to a change of sign in its quadratic form) into the Leech lattice Λ, the unique 24-dimensional positive-definite even unimodular lattice containing no vectors of squared norm 2. Furthermore, the action of G on L_G can be extended to an action on the whole of Λ, such that the sublattice $\Lambda^G \subset \Lambda$ of vectors fixed by G is the orthogonal complement of L_G in Λ. This construction implies that G must be a subgroup of $\mathrm{Co}_0 \equiv \mathrm{Aut}(\Lambda)$ that fixes a sublattice Λ^G of rank $4 + d$. Conversely, it can be shown that any such subgroup of $\mathrm{Aut}(\Lambda)$ is the symmetry group of some K3 sigma-model.

This leaves us with characterising the possible subgroups of the finite group $\mathrm{Co}_0 \equiv \mathrm{Aut}(\Lambda)$ that stabilise a suitable sublattice; problems of this kind have been studied in the mathematical literature before. In particular, the stabilisers of sublattices of rank at least 4 are, generically, the subgroups of $\mathbb{Z}_2^{11} : \mathbb{M}_{24}$ described in case (i) of the theorem above. The three cases (ii), (iii), (iv) arise when the invariant sublattice Λ^G is contained in some $\mathcal{S}$-lattice $S \subset \Lambda$. An $\mathcal{S}$-lattice S is a primitive sublattice of Λ such that each vector of S is congruent modulo $2S$ to a vector of norm 0, 4 or 6. Up to isomorphisms, there are only three kind of $\mathcal{S}$-lattices of rank at least four; their properties are summarised in the following table:

Name	type	rk S	Stab(S)	Aut(S)
$(A_2 \oplus A_2)'(3)$	$2^9 3^6$	4	$\mathbb{Z}_3^4 : A_6$	$\mathbb{Z}_2 \times (S_3 \times S_3).\mathbb{Z}_2$
$A_4^*(5)$	$2^5 3^{10}$	4	$5^{1+2} : \mathbb{Z}_4$	$\mathbb{Z}_2 \times S_5$
$E_6^*(3)$	$2^{27} 3^{36}$	6	$3^{1+4} : \mathbb{Z}_2$	$\mathbb{Z}_2 \times W(E_6)$.

Here, S is characterised by the type $2^p 3^q$, which indicates that S contains p pairs of opposite vectors of norm 4 (type 2) and q pairs of opposite vectors of norm 6 (type 3).

The group $\mathrm{Stab}(S)$ is the pointwise stabiliser of S in Co_0 and $\mathrm{Aut}(S)$ is the quotient of the setwise stabiliser of S modulo its pointwise stabiliser $\mathrm{Stab}(S)$. The group $\mathrm{Aut}(S)$ always contains a central $\mathbb{Z}_2$ subgroup, generated by the transformation that inverts the sign of all vectors of the Leech lattice. The lattice of type $2^{27}3^{36}$ is isomorphic to the weight lattice (the dual of the root lattice) of E_6 with quadratic form rescaled by 3 (i.e. the roots in $E_6^*(3)$ have squared norm 6), and $\mathrm{Aut}(S)/\mathbb{Z}_2$ is isomorphic to the Weyl group $W(E_6)$ of E_6. Similarly, the lattice of type $2^5 3^{10}$ is the weight lattice of A_4 rescaled by 5, and $\mathrm{Aut}(S)/\mathbb{Z}_2$ is isomorphic to the Weyl group $W(A_4) \cong S_5$ of A_4. Finally, the type $2^9 3^6$ is the 3-rescaling of a lattice $(A_2 \oplus A_2)'$ obtained by adjoining to the root lattice $A_2 \oplus A_2$ an element $(e_1^*, e_2^*) \in A_2^* \oplus A_2^*$, with e_1^* and e_2^* of norm $2/3$. The latter $\mathcal{S}$-lattice can also be described as the sublattice of vectors of $E_6^*(3)$ that are orthogonal to an $A_2(3)$ sublattice of $E_6^*(3)$. The group $\mathrm{Aut}(S)/\mathbb{Z}_2$ is the product $(S_3 \times S_3).\mathbb{Z}_2$ of the Weyl groups $W(A_2) = S_3$, and the $\mathbb{Z}_2$ symmetry that exchanges the two A_2 and maps e_1^* to e_2^*.

The cases (ii)–(iv) of the above theorem correspond to Λ^G being isomorphic to $A_4^*(5)$ (case ii), to $(A_2 \oplus A_2)'(3)$ (case iii) or to a sublattice of $E_6^*(3)$ different from $(A_2 \oplus A_2)'(3)$ (case iv). In the cases (ii) and (iii), G is isomorphic to $\mathrm{Stab}(S)$. In case (iv), $\mathrm{Stab}(S)$ is, generically, a normal subgroup of G, and $G'' \cong G/\mathrm{Stab}(S)$ is a subgroup of $\mathrm{Aut}(S) \cong \mathbb{Z}_2 \times W(E_6)$ that fixes a sublattice $\Lambda^G \subseteq E_6^*(3)$, with $\Lambda^G \neq (A_2 \oplus A_2)'(3)$, of rank at least 4. The only non-trivial subgroups of $\mathbb{Z}_2 \times W(E_6)$ with these properties are $G'' = \mathbb{Z}_2$, which corresponds to Λ^G being orthogonal to a single vector of norm 6 in $E_6^*(3)$ (a rescaled root), and $G'' = \mathbb{Z}_2^2$, which corresponds to Λ^G being orthogonal to two orthogonal vectors of norm 6.[§] If Λ^G is orthogonal to two vectors $v_1, v_2 \in E_6^*(3)$ of norm 6, with $v_1 \cdot v_2 = -3$, then $\Lambda^G \cong (A_2 \oplus A_2)'(3)$ and case (iii) applies.

4 Symmetry groups of torus orbifolds

In this section we will prove that all K3 sigma-models that are realised as (possibly left-right asymmetric) orbifolds of $\mathbb{T}^4$ by a cyclic group have an 'exceptional' group of symmetries, i.e. their symmetries are not a subgroup of $\mathbb{M}_{24}$. Furthermore, these torus orbifolds account for most of the exceptional models (in particular, for all models in the cases (ii)–(iv) of the theorem). On the other hand, as we shall also explain, there are exceptional models in case (i) that are not cyclic torus orbifolds.

Our reasoning is somewhat reminiscent of the construction of [28, 29] in the context of Monstrous Moonshine. Any $\mathbb{Z}_n$-orbifold of a conformal field theory has an automorphism g of order n, called the *quantum symmetry*, which acts trivially on the untwisted sector and by multiplication by the phase $\exp(\frac{2\pi i k}{n})$ on the k-th twisted sector. Furthermore, the orbifold of the orbifold theory by the group generated by the quantum symmetry g, is equivalent to the original conformal field theory [30]. This observation is the key for characterising K3 models that can be realised as torus orbifolds:

A K3 model $\mathcal{C}$ is a $\mathbb{Z}_n$-orbifold of a torus model if and only if it has a symmetry g of order n such that $\mathcal{C}/\langle g\rangle$ is a consistent orbifold equivalent to a torus model.

[§] The possibility $G'' = \mathbb{Z}_4$ that has been considered in [7] has to be excluded, since there are no elements of order 4 in $W(E_6)$ that preserve a four-dimensional sublattice of $E_6^*(3)$.

In order to see this, suppose that $\mathcal{C}_{K3}$ is a K3 sigma-model that can be realised as a torus orbifold $\mathcal{C}_{K3} = \tilde{\mathcal{C}}_{\mathbb{T}^4}/\langle \tilde{g} \rangle$, where $\tilde{g}$ is a symmetry of order n of the torus model $\tilde{\mathcal{C}}_{\mathbb{T}^4}$. Then $\mathcal{C}_{K3}$ possesses a 'quantum symmetry' g of order n, such that the orbifold of $\mathcal{C}_{K3}$ by g describes again the original torus model, $\tilde{\mathcal{C}}_{\mathbb{T}^4} = \mathcal{C}_{K3}/\langle g \rangle$.

Conversely, suppose $\mathcal{C}_{K3}$ has a symmetry g of order n, such that the orbifold of $\mathcal{C}_{K3}$ by g is consistent, i.e. satisfies the level matching condition — this is the case if and only if the twining genus ϕ_g has a trivial multiplier system — and leads to a torus model $\mathcal{C}_{K3}/\langle g \rangle = \tilde{\mathcal{C}}_{\mathbb{T}^4}$. Then $\mathcal{C}_{K3}$ itself is a torus orbifold since we can take the orbifold of $\tilde{\mathcal{C}}_{\mathbb{T}^4}$ by the quantum symmetry associated to g, and this will, by construction, lead back to $\mathcal{C}_{K3}$.

Thus we conclude that $\mathcal{C} \equiv \mathcal{C}_{K3}$ can be realised as a torus orbifold if and only if $\mathcal{C}$ contains a symmetry g such that (i) ϕ_g has a trivial multiplier system; and (ii) the orbifold of $\mathcal{C}$ by g leads to a torus model $\tilde{\mathcal{C}}_{\mathbb{T}^4}$. It is believed that the orbifold of $\mathcal{C}$ by any $\mathcal{N} = (4,4)$-preserving symmetry group, if consistent, will describe a sigma-model with target space either a torus $\mathbb{T}^4$ or a K3 manifold. The two cases can be distinguished by calculating the elliptic genus; in particular, if the target space is a torus, the elliptic genus vanishes. Actually, since the space of weak Jacobi forms of weight zero and index one is 1-dimensional, this condition is equivalent to the requirement that the elliptic genus $\tilde{\phi}(\tau, z)$ of $\tilde{\mathcal{C}} = \mathcal{C}/\langle g \rangle$ vanishes at $z = 0$.

Next we recall that the elliptic genus of the orbifold by a group element g of order $n = o(g)$ is given by the usual orbifold formula

$$\tilde{\phi}(\tau, z) = \frac{1}{n} \sum_{i,j=1}^{n} \phi_{g^i, g^j}(\tau, z) \ , \tag{4.1}$$

where $\phi_{g^i,g^j}(\tau, z)$ is the twining genus for g^j in the g^i-twisted sector; this can be obtained by a modular transformation from the untwisted twining genus $\phi_{g^d}(\tau, z)$ with $d = \gcd(i, j, n)$. As we have explained above, it is enough to evaluate the elliptic genus for $z = 0$. Then

$$\phi_{g^d}(\tau, z = 0) = \mathrm{Tr}_{\mathbf{24}}(g^d) \ , \tag{4.2}$$

where $\mathrm{Tr}_{\mathbf{24}}(g^d)$ is the trace of g^d over the 24-dimensional space of RR ground states, and since (4.2) is constant (and hence modular invariant) we conclude that

$$\tilde{\phi}(\tau, 0) = \frac{1}{n} \sum_{i,j=1}^{n} \mathrm{Tr}_{\mathbf{24}}(g^{\gcd(i,j,n)}) \ . \tag{4.3}$$

According to the theorem in section 3, all symmetry groups of K3 sigma-models are subgroups of Co_0 and, in fact, $\mathrm{Tr}_{\mathbf{24}}(g^d)$ coincides with the trace of $g^d \in \mathrm{Co}_0$ in the standard 24-dimensional representation of Co_0. Thus, the elliptic genus of the orbifold model $\tilde{\mathcal{C}} = \mathcal{C}/\langle g \rangle$ only depends on the conjugacy class of g in Co_0. The group Co_0 contains 167 conjugacy classes, but only 42 of them contain symmetries that are realised by some K3 sigma-model, i.e. elements that fix at least a four-dimensional subspace in the standard 24-dimensional representation of Co_0. If $\mathrm{Tr}_{\mathbf{24}}(g) \neq 0$ (this happens for 31 of the above 42 conjugacy classes), the twining genus $\phi_g(\tau, z)$ has necessarily a trivial multiplier system, and the orbifold $\mathcal{C}/\langle g \rangle$ is consistent. These classes are listed in the following table, together with the dimension of the space that is fixed by g, the trace over the 24-dimensional representation, and the elliptic genus $\tilde{\phi}(\tau, z = 0)$ of the orbifold model $\tilde{\mathcal{C}}$ (we underline the classes that restrict to $\mathbb{M}_{24}$ conjugacy classes):

Co_0-class	$\underline{\text{1A}}$	$\underline{\text{2B}}$	2C	$\underline{\text{3B}}$	3C	4B	$\underline{\text{4E}}$	4F	$\underline{\text{5B}}$	5C	6G	6H	6I	$\underline{\text{6K}}$	6L	6M	$\underline{\text{7B}}$
dim fix	24	16	8	12	6	8	10	6	8	4	6	6	6	8	4	4	6
$\mathrm{Tr}_{\mathbf{24}}(g)$	24	8	−8	6	−3	8	4	−4	4	−1	−4	4	5	2	−2	−1	3
$\tilde{\phi}(\tau, 0)$	24	24	0	24	0	24	24	0	24	0	0	24	24	24	0	0	24

Co_0-class	8D	$\underline{\text{8G}}$	8H	9C	10F	10G	10H	$\underline{\text{11A}}$	12I	12L	12N	12O	$\underline{\text{14C}}$	$\underline{\text{15D}}$
dim fix	4	6	4	4	4	4	4	4	4	4	4	4	4	4
$\mathrm{Tr}_{\mathbf{24}}(g)$	4	2	−2	3	−2	2	3	2	2	1	−2	2	1	1
$\tilde{\phi}(\tau, 0)$	24	24	0	24	0	24	24	24	24	24	0	24	24	24

Note that the elliptic genus of the orbifold theory $\tilde{\mathcal{C}}$ is always 0 or 24, corresponding to a torus or a K3 sigma-model, respectively. Out of curiosity, we have also computed the putative elliptic genus $\tilde{\phi}(\tau, 0)$ for the 11 classes of symmetries g with $\mathrm{Tr}_{24}(g) = 0$ for which we do not expect the orbifold to make sense — the corresponding twining genus ϕ_g will typically have a non-trivial multiplier system, and hence the orbifold will not satisfy level-matching. Indeed, for almost none of these cases is $\tilde{\phi}(\tau, 0)$ equal to 0 or 24, thus signaling an inconsistency of the orbifold model:

Co_0-class	$\underline{\text{2D}}$	$\underline{\text{3D}}$	4D	$\underline{\text{4G}}$	$\underline{\text{4H}}$	6O	$\underline{\text{6P}}$	8C	8I	$\underline{\text{10J}}$	$\underline{\text{12P}}$
dim fix	12	8	4	8	6	6	4	4	4	4	4
$\mathrm{Tr}_{\mathbf{24}}(g)$	0	0	0	0	0	0	0	0	0	0	0
$\tilde{\phi}(\tau, 0)$	12	8	0	12	6	12	4	12	6	12	12

The only exception is the class 4D, which might define a consistent orbifold (a torus model). It follows that a K3 model $\mathcal{C}$ is the $\mathbb{Z}_n$-orbifold of a torus model if and only if it contains a symmetry g in one of the classes

$$\begin{aligned} &\text{2C, 3C, 4F, 5C, 6G, 6L, 6M, 8H, 10F, 12N,} \\ &\text{4B, 4D, 6H, 6I, 8C, 8D, 9C, 10G, 10H, 12I, 12L, 12O} \end{aligned} \tag{4.4}$$

of Co_0.[¶] Here we have also included (in the second line) those classes of elements $g \in \mathrm{Co}_0$ for which $\mathcal{C}/\langle g^i \rangle$ is a torus model, for some power $i > 1$. Our main observation is now that none of the Co_0 classes in (4.4) restricts to a class in $\mathbb{M}_{24}$, i.e.

All K3 models that are realised as $\mathbb{Z}_n$-orbifolds of torus models are exceptional. In particular, the quantum symmetry is not an element of $\mathbb{M}_{24}$.

One might ask whether the converse is also true, i.e. whether all exceptional models are cyclic torus orbifolds. This is not quite the case: for example, the classification theorem of section 3 predicts the existence of models with a symmetry group $G \cong GL_2(3)$ (the group of 2×2 invertible matrices on the field $\mathbb{F}_3$ with 3 elements). The group G contains no elements in the classes (4.4), so the model is not a cyclic torus orbifold; on the other hand, G contains elements in the class 8I of Co_0, which does not restrict to $\mathbb{M}_{24}$. A second counterexample is a family of models with a symmetry g in the class 6O of Co_0. A generic point of this family is not a cyclic torus model (although some special points are), since the full symmetry group is generated by g and contains no elements in (4.4). Both these counterexamples belong to case (i) of the general classification theorem. In fact, we can prove that

---

[¶] We should emphasise that for us the term 'orbifold' always refers to a conformal field theory (rather than a geometrical) construction. Although a non-linear sigma-model on a geometric orbifold $M/\mathbb{Z}_N$ always admits an interpretation as a CFT orbifold, the converse is not always true. In particular, there exist asymmetric orbifold constructions that do not have a direct geometric interpretation, see for example section 5.

The symmetry group G of a K3 sigma-model $\mathcal{C}$ contains a subgroup $3^{1+4} : \mathbb{Z}_2$ (cases (iii) and (iv) of the theorem) if and only if $\mathcal{C}$ is a $\mathbb{Z}_3$-orbifold of a torus model. Furthermore, $G = 5^{1+2} : \mathbb{Z}_4$ (case (ii)) if and only if $\mathcal{C}$ is a $\mathbb{Z}_5$-orbifold of a torus model.

The proof goes as follows. All subgroups of Co_0 of the form $3^{1+4} : \mathbb{Z}_2$ (respectively, $5^{1+2} : \mathbb{Z}_4$) contain an element in the class 3C (resp., 5C), and therefore the corresponding models are $\mathbb{Z}_3$ (resp., $\mathbb{Z}_5$) torus orbifolds. Conversely, consider a $\mathbb{Z}_3$-orbifold of a torus model. Its symmetry group G contains the quantum symmetry g in class 3C of Co_0. (It must contain a symmetry generator of order three whose orbifold leads to a torus, and 3C is then the only possibility.) The sublattice $\Lambda^{\langle g\rangle} \subset \Lambda$ fixed by g is the $\mathcal{S}$-lattice $2^{27}3^{36}$ [31]. From the classification theorem, we know that G is the stabiliser of a sublattice $\Lambda^G \subset \Lambda$ of rank at least 4. Since $\Lambda^G \subseteq \Lambda^{\langle g\rangle}$, G contains as a subgroup the stabiliser of $\Lambda^{\langle g\rangle}$, namely $3^{1+4} : \mathbb{Z}_2$.

Analogously, a $\mathbb{Z}_5$ torus orbifold always has a symmetry in class 5C, whose fixed sublattice $\Lambda^{\langle g\rangle}$ is the $\mathcal{S}$-lattice $2^5 3^{10}$ [31]. Since $\Lambda^{\langle g\rangle}$ has rank 4 and is primitive, $\Lambda^G = \Lambda^{\langle g\rangle}$ and the symmetry group G must be the stabiliser $5^{1+2} : \mathbb{Z}_4$ of $\Lambda^{\langle g\rangle}$.

It was shown in [7] that the Gepner model $(1)^6$ corresponds to the case (ii) of the classification theorem. It thus follows from the above reasoning that it must indeed be equivalent to a $\mathbb{Z}_3$-orbifold of $\mathbb{T}^4$, see also [27]. (We shall also study these orbifolds more systematically in section 6.) In the next section, we will provide an explicit construction of a $\mathbb{Z}_5$-orbifold of a torus model and show that its symmetry group is $5^{1+2} : \mathbb{Z}_4$, as predicted by the above analysis.

5 A K3 model with symmetry group $5^{1+2} : \mathbb{Z}_4$

In this section we will construct a supersymmetric sigma-model on $\mathbb{T}^4$ with a symmetry g of order 5 commuting with an $\mathcal{N} = (4, 4)$ superconformal algebra and acting asymmetrically on the left- and on the right-moving sector. The orbifold of this model by g will turn out to be a well-defined SCFT with $\mathcal{N} = (4, 4)$ (in particular, the level matching condition is satisfied) that can be interpreted as a non-linear sigma-model on K3. We will argue that the group of symmetries of this model is $G = 5^{1+2}.\mathbb{Z}_4$, one of the exceptional groups considered in the general classification theorem.

5.1 The torus model

Let us consider a supersymmetric sigma-model on the torus $\mathbb{T}^4$. Geometrically, we can characterise the theory in terms of a metric and a Kalb-Ramond field, but it is actually more convenient to describe it simply as a conformal field theory that is generated by the following fields: four left-moving $u(1)$ currents $\partial X^a(z)$, $a = 1, \ldots, 4$, four free fermions $\psi^a(z)$, $a = 1, \ldots, 4$, their right-moving analogues $\bar{\partial} X^a(\bar{z}), \tilde{\psi}^a(\bar{z})$, as well as some winding-momentum fields $V_\lambda(z, \bar{z})$ that are associated to vectors λ in an even unimodular lattice $\Gamma^{4,4}$ of signature $(4,4)$. The mode expansions of the left-moving fields are

$$\partial X^a(z) = \sum_{n\in\mathbb{Z}} \alpha_n z^{-n-1} , \qquad \psi^a = \sum_{n\in\mathbb{Z}+\nu} \psi_n z^{-n-\frac{1}{2}} , \tag{5.1}$$

where $\nu = 0, 1/2$ in the R- and NS-sector, respectively. Furthermore, we have the usual commutation relations

$$[\alpha^a_m, \alpha^b_n] = m\, \delta^{ab}\, \delta_{m,-n} \qquad\qquad \{\psi^a_m, \psi^b_n\} = \delta^{ab}\, \delta_{m,-n} . \tag{5.2}$$

Analogous statements also hold for the right-moving modes $\tilde{\alpha}_n$ and $\tilde{\psi}_n$. The vectors $\lambda \equiv (\lambda_L, \lambda_R) \in \Gamma^{4,4}$ describe the eigenvalues of the corresponding state with respect to the left- and right-moving zero modes α^a_0 and $\tilde{\alpha}^a_0$, respectively. In these conventions the inner product on $\Gamma^{4,4}$ is given as

$$(\lambda, \lambda') = \lambda_L \cdot \lambda'_L - \lambda_R \cdot \lambda'_R . \tag{5.3}$$

5.1.1 Continuous and discrete symmetries

Any torus model contains an $\hat{\mathfrak{su}}(2)_1 \oplus \hat{\mathfrak{su}}(2)_1 \oplus \hat{\mathfrak{u}}(1)^4$ current algebra, both on the left and on the right. Here, the $\hat{\mathfrak{u}}(1)^4$ currents are the ∂X^a, $a = 1, \ldots, 4$, while $\hat{\mathfrak{su}}(2)_1 \oplus \hat{\mathfrak{su}}(2)_1 = \hat{\mathfrak{so}}(4)_1$ is generated by the fermionic bilinears

$$a^3 := \bar{\psi}^{(1)}\psi^{(1)} + \bar{\psi}^{(2)}\psi^{(2)} \qquad a^+ := \bar{\psi}^{(1)}\bar{\psi}^{(2)} \qquad a^- := -\psi^{(1)}\psi^{(2)} , \tag{5.4}$$

$$\hat{a}^3 := \bar{\psi}^{(1)}\psi^{(1)} - \bar{\psi}^{(2)}\psi^{(2)} \qquad \hat{a}^+ := \bar{\psi}^{(1)}\psi^{(2)} \qquad \hat{a}^- := -\psi^{(1)}\bar{\psi}^{(2)} , \tag{5.5}$$

where

$$\psi^{(1)} = \tfrac{1}{\sqrt{2}}(\psi^1 + i\psi^2) \qquad\qquad \psi^{(2)} = \tfrac{1}{\sqrt{2}}(\psi^3 + i\psi^4) \tag{5.6}$$

$$\bar{\psi}^{(1)} = \tfrac{1}{\sqrt{2}}(\psi^1 - i\psi^2) \qquad\qquad \bar{\psi}^{(2)} = \tfrac{1}{\sqrt{2}}(\psi^3 - i\psi^4) . \tag{5.7}$$

At special points in the moduli space, where the $\Gamma^{4,4}$ lattice contains vectors of the form $(\lambda_L, 0)$ with $\lambda_L^2 = 2$, the bosonic $\mathfrak{u}(1)^4$ algebra is enhanced to some non-abelian algebra $\mathfrak{g}$ of rank 4. There are generically 16 (left-moving) supercharges; they form four $(\mathbf{2}, \mathbf{2})$ representations of the $\mathfrak{su}(2) \oplus \mathfrak{su}(2)$ zero mode algebra from (5.4) and (5.5). Altogether, the chiral algebra at generic points is a *large* $\mathcal{N} = 4$ superconformal algebra.

We want to construct a model with a symmetry g of order 5, acting non-trivially on the fermionic fields, and commuting with the *small* $\mathcal{N} = 4$ subalgebras both on the left and on the right. A small $\mathcal{N} = 4$ algebra contains an $\hat{\mathfrak{su}}(2)_1$ current algebra and four supercharges in two doublets of $\mathfrak{su}(2)$. The symmetry g acts by an $\mathrm{O}(4, \mathbb{R})$ rotation on the left-moving fermions ψ^a, preserving the anti-commutation relations (5.2). Without loss of generality, we may assume that $\psi^{(1)}$ and $\bar{\psi}^{(1)}$ are eigenvectors of g with eigenvalues ζ and ζ^{-1}, where ζ is a primitive fifth root of unity

$$\zeta^5 = 1 \ , \tag{5.8}$$

and that the $\hat{\mathfrak{su}}(2)_1$ algebra preserved by g is (5.4). This implies that g acts on all the fermionic fields by

$$\psi^{(1)} \mapsto \zeta\, \psi^{(1)} \ , \quad \bar{\psi}^{(1)} \mapsto \zeta^{-1}\bar{\psi}^{(1)} \ , \quad \psi^{(2)} \mapsto \zeta^{-1}\psi^{(2)} \ , \quad \bar{\psi}^{(2)} \mapsto \zeta\, \bar{\psi}^{(2)} \ . \tag{5.9}$$

Note that the action of g on the fermionic fields can be described by $e^{\frac{2\pi i k}{5}\hat{a}^3_0}$ for some $k = 1, \ldots, 4$, where $\hat{a}^3$ is the current in the algebra (5.5). The four g-invariant supercharges can then be taken to be

$$\sqrt{2}\sum_{i=1}^{2} J^{(i)}\bar{\psi}^{(i)} \ , \quad \sqrt{2}\sum_{i=1}^{2} \bar{J}^{(i)}\psi^{(i)} \ , \quad \sqrt{2}(\bar{J}^{(1)}\bar{\psi}^{(2)} - \bar{J}^{(2)}\bar{\psi}^{(1)}) \ , \quad \sqrt{2}(J^{(1)}\psi^{(2)} - J^{(2)}\psi^{(1)}) \ , \tag{5.10}$$

where $J^{(1)}, \bar{J}^{(1)}, J^{(2)}, \bar{J}^{(2)}$ are suitable (complex) linear combinations of the left-moving currents ∂X^a, $a = 1, \ldots, 4$. In order to preserve the four supercharges, g must act with the same eigenvalues on the bosonic currents

$$J^{(1)} \mapsto \zeta\, J^{(1)} \ , \quad \bar{J}^{(1)} \mapsto \zeta^{-1}\bar{J}^{(1)} \ , \quad J^{(2)} \mapsto \zeta^{-1}J^{(2)} \ , \quad \bar{J}^{(2)} \mapsto \zeta\, \bar{J}^{(2)} \ . \tag{5.11}$$

A similar reasoning applies to the right-moving algebra with respect to an eigenvalue $\tilde{\zeta}$, with $\tilde{\zeta}^5 = 1$. For the symmetries with a geometric interpretation, the action on the left- and right-moving bosonic currents is induced by an $\mathrm{O}(4, \mathbb{R})$-transformation on the scalar fields X^a, $a, = 1, \ldots, 4$, representing the coordinates on the torus; then ζ and $\tilde{\zeta}$ are necessarily equal. In our treatment, we want to allow for the more general case where $\zeta \neq \tilde{\zeta}$.

The action of g on J^a and $\tilde{J}^a$ induces an $\mathrm{O}(4, 4, \mathbb{R})$-transformation on the lattice $\Gamma^{4,4}$. The transformation g is a symmetry of the model if and only if it induces an automorphism on $\Gamma^{4,4}$. In particular, it must act by an invertible integral matrix on any lattice basis. The requirement that the trace of this matrix (and of any power of it) must be integral, leads to the condition that

$$2(\zeta^i + \zeta^{-i} + \tilde{\zeta}^i + \tilde{\zeta}^{-i}) \in \mathbb{Z} \ , \tag{5.12}$$

for all $i \in \mathbb{Z}$. For g of order 5, this condition is satisfied by

$$\zeta = e^{\frac{2\pi i}{5}} \qquad \text{and} \qquad \tilde{\zeta} = e^{\frac{4\pi i}{5}} \ , \tag{5.13}$$

and this solution is essentially unique (up to taking powers of it or exchanging the definition of ζ and ζ^{-1}). Eq. (5.13) shows that a supersymmetry preserving symmetry of order 5 is necessarily left-right asymmetric, and hence does not have a geometric interpretation.

It is now clear how to construct a torus model with the symmetries (5.9) and (5.11). First of all, we need an automorphism g of $\Gamma^{4,4}$ of order five. Such an automorphism must have eigenvalues $\zeta, \zeta^2, \zeta^3, \zeta^4$, each corresponding to two independent eigenvectors $v^{(1)}_{\zeta^i}, v^{(2)}_{\zeta^i}$, $i = 1, \ldots, 4$, in $\Gamma^{4,4} \otimes \mathbb{C}$. Given the discussion above, see in particular (5.13), we now require that the vectors

$$v^{(1)}_{\zeta^1} , \quad v^{(2)}_{\zeta^1} , \quad v^{(1)}_{\zeta^4} , \quad v^{(2)}_{\zeta^4} \tag{5.14}$$

span a positive-definite subspace of $\Gamma^{4,4} \otimes \mathbb{C}$ (i.e. correspond to the left-movers), while the vectors

$$v^{(1)}_{\zeta^2} , \quad v^{(2)}_{\zeta^2} , \quad v^{(1)}_{\zeta^3} , \quad v^{(2)}_{\zeta^3} \tag{5.15}$$

span a negative-definite subspace of $\Gamma^{4,4} \otimes \mathbb{C}$ (i.e. correspond to the right-movers).

An automorphism g with the properties above can be explicitly constructed as follows. Let us consider the real vector space with basis vectors $x_1, \ldots, x_4$, and $y_1, \ldots, y_4$, and define a linear map g of order 5 by

$$g(x_i) = x_{i+1} , \qquad g(y_i) = y_{i+1} , \qquad\qquad i = 1, \ldots, 3 , \tag{5.16}$$

and

$$g(x_4) = -(x_1 + x_2 + x_3 + x_4) , \qquad g(y_4) = -(y_1 + y_2 + y_3 + y_4) . \tag{5.17}$$

A g-invariant bilinear form on the space is uniquely determined by the conditions

$$(x_i, x_i) = 0 = (y_i, y_i) , \qquad i = 1, \ldots, 4 \tag{5.18}$$

and

$$(x_1, x_2) = 1 , \quad (x_1, x_3) = (x_1, x_4) = -1 , \qquad (y_1, y_2) = 1 , \quad (y_1, y_3) = (y_1, y_4) = -1 , \tag{5.19}$$

as well as

$$(x_1, y_1) = 1 , \quad \text{and} \quad (x_i, y_1) = 0 , \quad (i = 2, 3, 4) . \tag{5.20}$$

The lattice spanned by these basis vectors is an indefinite even unimodular lattice of rank 8 and thus necessarily isomorphic to $\Gamma^{4,4}$. The g-eigenvectors can be easily constructed in terms of the basis vectors and one can verify that the eigenspaces have the correct signature.

This torus model has an additional $\mathbb{Z}_4$ symmetry group that preserves the superconformal algebra and normalises the group generated by g. The generator h of this group acts by

$$h(x_i) := g^{1-i}(x_1 + x_4 + 2y_1 + y_2 + y_3 + y_4) , \tag{5.21}$$

$$h(y_i) := g^{1-i}(-2x_1 - x_2 - x_3 - x_4 - y_1 - y_3 - y_4) , \qquad i = 1, \ldots, 4 , \tag{5.22}$$

on the lattice vectors. The g-eigenvectors $v^{(a)}_{\zeta^i}$, $a = 1, 2$, $i = 1, \ldots, 4$ can be defined as

$$v^{(1)}_{\zeta^i} := \sum_{j=0}^{4} \zeta^{-ij} g^j(x_1 + h(x_1)) , \qquad v^{(2)}_{\zeta^i} := \sum_{j=0}^{4} \zeta^{-ij} g^j(x_1 - h(x_1)) , \tag{5.23}$$

so that

$$h(v^{(1)}_{\zeta^i}) = -v^{(2)}_{\zeta^{-i}} , \qquad h(v^{(2)}_{\zeta^i}) = v^{(1)}_{\zeta^{-i}} . \tag{5.24}$$

Correspondingly, the action of h on the left-moving fields is

$$\psi^{(1)} \mapsto -\psi^{(2)}\ , \quad \psi^{(2)} \mapsto \psi^{(1)}\ , \quad \bar{\psi}^{(1)} \mapsto -\bar{\psi}^{(2)}\ , \quad \bar{\psi}^{(2)} \mapsto \bar{\psi}^{(1)}\ , \tag{5.25}$$

$$J^{(1)} \mapsto -J^{(2)}\ , \quad J^{(2)} \mapsto J^{(1)}\ , \quad \bar{J}^{(1)} \mapsto -\bar{J}^{(2)}\ , \quad \bar{J}^{(2)} \mapsto \bar{J}^{(1)}\ , \tag{5.26}$$

and the action on the right-moving fields is analogous. It is immediate to verify that the generators of the superconformal algebra are invariant under this transformation.

5.2 The orbifold theory

Next we want to consider the orbifold of this torus theory by the group $\mathbb{Z}_5$ that is generated by g.

5.2.1 The elliptic genus

The elliptic genus of the orbifold theory can be computed by summing over the $\mathrm{SL}(2,\mathbb{Z})$ images of the untwisted sector contribution, which in turn is given by

$$\phi^U(\tau,z) = \frac{1}{5}\sum_{k=0}^{4} \phi_{1,g^k}(\tau,z)\ , \tag{5.27}$$

where

$$\phi_{1,g^k}(\tau,z) = \mathrm{Tr}_{\mathrm{RR}}(g^k\, q^{L_0-\frac{c}{24}}\bar{q}^{\tilde{L}_0-\frac{\tilde{c}}{24}} y^{2J_0}(-1)^{F+\tilde{F}})\ . \tag{5.28}$$

The $k=0$ contribution, i.e. the elliptic genus of the original torus theory, is zero. Each g^k-contribution, for $k=1,\ldots,4$, is the product of a factor coming from the ground states, one from the oscillators and one from the momenta

$$\phi_{1,g^k}(\tau,z) = \phi^{\mathrm{gd}}_{1,g^k}(\tau,z)\,\phi^{\mathrm{osc}}_{1,g^k}(\tau,z)\,\phi^{\mathrm{mom}}_{1,g^k}(\tau,z)\ . \tag{5.29}$$

These contributions are, respectively,

$$\phi^{\mathrm{gd}}_{1,g^k}(\tau,z) = y^{-1}(1-\zeta^k y)(1-\zeta^{-k}y)(1-\zeta^{2k})(1-\zeta^{-2k}) = 2y^{-1}+2y+1\ , \tag{5.30}$$

$$\phi^{\mathrm{osc}}_{1,g^k}(\tau,z) = \prod_{n=1}^{\infty}\frac{(1-\zeta^k y q^n)(1-\zeta^{-k}yq^n)(1-\zeta^k y^{-1}q^n)(1-\zeta^{-k}y^{-1}q^n)}{(1-\zeta^k q^n)^2(1-\zeta^{-k}q^n)^2}\ , \tag{5.31}$$

and

$$\phi^{\mathrm{mom}}_{1,g^k}(\tau,z) = 1\ , \tag{5.32}$$

where the last result follows because the only g-invariant state of the form (k_L,k_R) is the vacuum $(0,0)$. Thus we have

$$\phi_{1,g^k}(\tau,z) = 5\,\frac{\vartheta_1(\tau,z+\frac{k}{5})\,\vartheta_1(\tau,z-\frac{k}{5})}{\vartheta_1(\tau,\frac{k}{5})\,\vartheta_1(\tau,-\frac{k}{5})}\ , \tag{5.33}$$

where

$$\vartheta_1(\tau,z) = -iq^{1/8}y^{-\frac{1}{2}}(y-1)\prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^n)\ , \tag{5.34}$$

is the first Jacobi theta function. Modular transformations of $\phi_{1,g^k}(\tau,z)$ reproduce the twining genera in the twisted sector

$$\phi_{g^l,g^k}(\tau,z) = \mathrm{Tr}_{\mathcal{H}^{(l)}}\left(g^k\, q^{L_0-\frac{c}{24}}\,\bar{q}^{\tilde{L}_0-\frac{\tilde{c}}{24}}y^{2J_0}(-1)^{F+\tilde{F}}\right)\ , \tag{5.35}$$

and using the modular properties of the theta function we obtain

$$\phi_{g^l,g^k}(\tau,z) = 5\,\frac{\vartheta_1(\tau,z+\frac{k}{5}+\frac{l\tau}{5})\,\vartheta_1(\tau,z-\frac{k}{5}-\frac{l\tau}{5})}{\vartheta_1(\tau,\frac{k}{5}+\frac{l\tau}{5})\,\vartheta_1(\tau,-\frac{k}{5}-\frac{l\tau}{5})}\ , \tag{5.36}$$

for $k,l\in\mathbb{Z}/5\mathbb{Z}$, $(k,l)\neq(0,0)$. The elliptic genus of the full orbifold theory is then

$$\phi_{\rm orb}(\tau,z) = \frac{1}{5}\sum_{k,l\in\mathbb{Z}/5\mathbb{Z}}\phi_{g^l,g^k}(\tau,z) = \sum_{\substack{k,l\in\mathbb{Z}/5\mathbb{Z}\\(k,l)\neq(0,0)}}\frac{\vartheta_1(\tau,z+\frac{k}{5}+\frac{l\tau}{5})\,\vartheta_1(\tau,z-\frac{k}{5}-\frac{l\tau}{5})}{\vartheta_1(\tau,\frac{k}{5}+\frac{l\tau}{5})\,\vartheta_1(\tau,-\frac{k}{5}-\frac{l\tau}{5})}\ . \tag{5.37}$$

Since $\phi_{g^k,g^l}(\tau,0)=5$ for all $(k,l)\neq(0,0)$, we have

$$\phi_{\rm orb}(\tau,0) = \frac{1}{5}\sum_{\substack{k,l\in\mathbb{Z}/5\mathbb{Z}\\(k,l)\neq(0,0)}} 5 = 24\ , \tag{5.38}$$

which shows that the orbifold theory is a non-linear sigma-model on K3. In particular, the untwisted sector has 4 RR ground states, while each of the four twisted sectors contains 5 RR ground states. For the following it will be important to understand the structure of the various twisted sectors in detail.

5.2.2 The twisted sectors

In the g^k-twisted sector, let us consider a basis of g-eigenvectors for the currents and fermionic fields. For a given eigenvalue ζ^i, $i\in\mathbb{Z}/5\mathbb{Z}$, of g^k, the corresponding currents $J^{i,a}$ and fermionic fields $\psi^{i,b}$ (where a,b labels distinct eigenvectors with the same eigenvalue) have a mode expansion

$$J^{i,a}(z) = \sum_{n\in\frac{i}{5}+\mathbb{Z}}\alpha^{i,a}_n z^{-n-1}\ ,\qquad \psi^{i,a}(z) = \sum_{r\in\frac{i}{5}+\nu+\mathbb{Z}}\psi^{i,a}_r z^{-r-1/2}\ , \tag{5.39}$$

where $\nu=1/2$ in the NS- and $\nu=0$ in the R-sector. The ground states of the g^k-twisted sector are characterised by the conditions

$$\alpha^{i,a}_n|m,k\rangle = \tilde{\alpha}^{i,a}_n|m,k\rangle = 0\ ,\qquad \forall\ n>0,\ i,\ a\ , \tag{5.40}$$

$$\psi^{i,b}_r|m,k\rangle = \tilde{\psi}^{i,b}_r|m,k\rangle = 0\ ,\qquad \forall\ r>0,\ i,\ b\ , \tag{5.41}$$

where $|m,k\rangle$ denotes the $m^{\rm th}$ ground state in the g^k-twisted sector. Note that since none of the currents are g-invariant, there are no current zero modes in the g^k-twisted sector, and similarly for the fermions. For a given k, the states $|m,k\rangle$ have then all the same conformal dimension, which can be calculated using the commutation relation $[L_{-1},L_1]=2L_0$ or read off from the leading term of the modular transform of the twisted character (5.35). In the g^k-twisted NS-NS-sector the ground states have conformal dimension

$$\text{NS-NS } g^k\text{-twisted:} \qquad h = \frac{k}{5} \qquad \text{and} \qquad \tilde{h} = \frac{2k}{5} \ , \tag{5.42}$$

while in the RR-sector we have instead

$$\text{R-R } g^k\text{-twisted:} \qquad h = \tilde{h} = \frac{1}{4} \ . \tag{5.43}$$

In particular, level matching is satisfied, and thus the asymmetric orbifold is consistent [32]. The full g^k-twisted sector is then obtained by acting with the negative modes of the currents and the fermionic fields on the ground states $|m,k\rangle$.

Let us have a closer look at the ground states of the g^k twisted sector; for concreteness we shall restrict ourselves to the case $k=1$, but the modifications for general k are minor (see below). The vertex operators $V_\lambda(z,\bar{z})$ associated to $\lambda \in \Gamma^{4,4}$, act on the ground states $|m,1\rangle$ by

$$\lim_{z\to 0} V_\lambda(z,\bar{z})|m,1\rangle = e_\lambda |m,1\rangle \ , \tag{5.44}$$

where e_λ are operators commuting with all current and fermionic oscillators and satisfying

$$e_\lambda \, e_\mu = \epsilon(\lambda,\mu) \, e_{\lambda+\mu} \ , \tag{5.45}$$

for some fifth root of unity $\epsilon(\lambda,\mu)$. The vertex operators V_λ and V_μ must be local relative to one another, and this is the case provided that (see the appendix)

$$\frac{\epsilon(\lambda,\mu)}{\epsilon(\mu,\lambda)} = C(\lambda,\mu) \ , \tag{5.46}$$

where

$$C(\lambda,\mu) = \prod_{i=1}^{4} (\zeta^i)^{(g^i(\lambda),\mu)} = \zeta^{(P_g(\lambda),\mu)} \qquad \text{with} \qquad P_g(\lambda) = \sum_{i=1}^{4} i g^i(\lambda) \ . \tag{5.47}$$

The factor $C(\lambda,\mu)$ has the properties

$$C(\lambda,\mu_1+\mu_2) = C(\lambda,\mu_1)\,C(\lambda,\mu_2) \ , \qquad C(\lambda_1+\lambda_2,\mu) = C(\lambda_1,\mu)\,C(\lambda_2,\mu) \ , \tag{5.48}$$

$$C(\lambda,\mu) = C(\mu,\lambda)^{-1} \ , \tag{5.49}$$

$$C(\lambda,\mu) = C(g(\lambda),g(\mu)) \ . \tag{5.50}$$

Because of (5.48), $C(\lambda,0) = C(0,\lambda) = 1$ for all $\lambda \in \Gamma^{4,4}$, and we can set

$$e_0 = 1 \ , \tag{5.51}$$

so that $\epsilon(0,\lambda) = 1 = \epsilon(\lambda,0)$. More generally, for the vectors λ in the sublattice

$$R := \{\lambda \in \Gamma^{4,4} \mid C(\lambda,\mu) = 1 \ , \text{ for all } \mu \in \Gamma^{4,4}\} \subset \Gamma^{4,4} \ , \tag{5.52}$$

we have $C(\lambda+\mu_1,\mu_2) = C(\mu_1,\mu_2)$, for all $\mu_1,\mu_2 \in \Gamma^{4,4}$, so that we can set

$$e_{\mu+\lambda} = e_\mu \ , \qquad \forall \lambda \in R \ , \quad \mu \in \Gamma^{4,4} \ . \tag{5.53}$$

Thus, we only need to describe the operators corresponding to representatives of the group $\Gamma^{4,4}/R$. The vectors $\lambda \in R$ are characterised by

$$(P_g(\lambda), \mu) \equiv 0 \mod 5 \ , \qquad \text{for all } \mu \in \Gamma^{4,4} \ , \tag{5.54}$$

and since $\Gamma^{4,4}$ is self-dual this condition is equivalent to

$$P_g(\lambda) \in 5\,\Gamma^{4,4} \ . \tag{5.55}$$

Since g has no invariant subspace, we have the identity

$$1 + g + g^2 + g^3 + g^4 = 0 \tag{5.56}$$

that implies (see (5.47))

$$P_g \circ (1-g) = (1-g) \circ P_g = -5 \cdot \mathbf{1} \ . \tag{5.57}$$

Thus, $\lambda \in R$ if and only if

$$P_g(\lambda) = P_g \circ (1-g)(\tilde{\lambda}) \ , \tag{5.58}$$

for some $\tilde{\lambda} \in \Gamma^{4,4}$, and since P_g has trivial kernel (see (5.57)), we finally obtain

$$R = (1-g)\,\Gamma^{4,4} \ . \tag{5.59}$$

Since also $(1-g)$ has trivial kernel, R has rank 8 and $\Gamma^{4,4}/R$ is a finite group. Furthermore,

$$|\Gamma^{4,4}/R| = \det(1-g) = 25 \ , \tag{5.60}$$

and, since $5\,\Gamma^{4,4} \subset R$, the group $\Gamma^{4,4}/R$ has exponent 5. The only possibility is

$$\Gamma^{4,4}/R \cong \mathbb{Z}_5 \times \mathbb{Z}_5 \ . \tag{5.61}$$

Let $x, y \in \Gamma^{4,4}$ be representatives for the generators of $\Gamma^{4,4}/R$. By (5.49), we know that $C(x,x) = C(y,y) = 1$, so that $C(x,y) \neq 1$ (otherwise C would be trivial over the whole $\Gamma^{4,4}$), and we can choose x, y such that

$$C(x,y) = \zeta \ . \tag{5.62}$$

Thus, the ground states form a representation of the algebra of operators generated by e_x, e_y, satisfying

$$e_x^5 = 1 = e_y^5 \ , \qquad e_x e_y = \zeta e_y e_x \ . \tag{5.63}$$

The group generated by e_x and e_y is the extra-special group 5^{1+2}, and all its non-abelian irreducible representations[‖] are five dimensional.

In particular, for the representation on the g-twisted ground states, we can choose a basis of e_x-eigenvectors

$$|m;1\rangle \quad \text{with} \quad e_x|m;1\rangle = \zeta^m |m;1\rangle \ , \qquad m \in \mathbb{Z}/5\mathbb{Z} \ , \tag{5.64}$$

[‖] We call a representation non-abelian if the central element does not act trivially.

and define the action of the operators e_y by

$$e_y|m;1\rangle = |m+1;1\rangle \ . \tag{5.65}$$

For any vector $\lambda \in \Gamma^{4,4}$, there are unique $a, b \in \mathbb{Z}/5\mathbb{Z}$ such that $\lambda = ax + by + (1-g)(\mu)$ for some $\mu \in \Gamma^{4,4}$ and we define[**]

$$e_\lambda := e_x^a e_y^b \ . \tag{5.66}$$

Since $g(\lambda) = ax + by + (1-g)(g(\mu) - ax - by)$, by (5.53) we have

$$e_{g(\lambda)} = e_\lambda \ , \tag{5.67}$$

so that, with respect to the natural action $g(e_\lambda) := e_{g(\lambda)}$, the algebra is g-invariant. This is compatible with the fact that all ground states have the same left and right conformal weights h and $\tilde{h}$, so that the action of $g = e^{2\pi i(h-\tilde{h})}$ is proportional to the identity.

The construction of the g^k-twisted sector, for $k = 2, 3, 4$, is completely analogous to the g^1-twisted case, the only difference being that the root ζ in the definition of $C(\lambda, \mu)$ should be replaced by ζ^k. Thus, one can define operators $e_x^{(k)}, e_y^{(k)}$ on the g^k-twisted sector, for each $k = 1, \ldots, 4$, satisfying

$$(e_x^{(k)})^5 = 1 = (e_y^{(k)})^5 \ , \qquad e_x^{(k)} e_y^{(k)} = \zeta^k e_y^{(k)} e_x^{(k)} \ . \tag{5.68}$$

The action of these operators on the analogous basis $|m;k\rangle$ with $m \in \mathbb{Z}/5\mathbb{Z}$ is then

$$e_x^{(k)}|m;k\rangle = \zeta^m |m;k\rangle \ , \quad e_y^{(k)}|m;k\rangle = |m+k;k\rangle \ . \tag{5.69}$$

5.2.3 Spectrum and symmetries

The spectrum of the actual orbifold theory is finally obtained from the above twisted sectors by projecting onto the g-invariant states; technically, this is equivalent to restricting to the states for which the difference of the left- and right- conformal dimensions is integer, $h - \tilde{h} \in \mathbb{Z}$. In particular, the RR ground states (5.69) in each (twisted) sector have $h = \tilde{h} = 1/4$, so that they all survive the projection. Thus, the orbifold theory has 4 RR ground states in the untwisted sector (the spectral flow generators), forming a $(\mathbf{2}, \mathbf{2})$ representation of $\mathfrak{su}(2)_L \oplus \mathfrak{su}(2)_R$, and 5 RR ground states in each twisted sector, which are singlets of $\mathfrak{su}(2)_L \oplus \mathfrak{su}(2)_R$. In total there are therefore 24 RR ground states, as expected for a non-linear sigma-model on K3. (Obviously, we are here just reproducing what we already saw in (5.38).)

Next we want to define symmetry operators acting on the orbifold theory. First we can construct operators e_λ associated to $\lambda \in \Gamma^{4,4}$, that will form the extra special group 5^{1+2}. They are defined to act by $e_\lambda^{(k)}$ on the g^k-twisted sector. The action of the untwisted sector preserves the subspaces $\mathcal{H}_m^U$, $m \in \mathbb{Z}/5\mathbb{Z}$, of states with momentum of the form $\lambda = nx + my + (1-g)(\mu)$, for some $n \in \mathbb{Z}$ and $\mu \in \Gamma^{4,4}$. Let us denote by $T_{m;k}$ a generic vertex operator associated with a g^k-twisted state, $k = 1, \ldots, 4$, with e_x-eigenvalue ζ^m,

---

[**] The ordering of e_x and e_y in this definition is arbitrary; however, any other choice corresponds to a redefinition $\tilde{e}_\lambda = c(\lambda)e_\lambda$, for some fifth root of unity $c(\lambda)$, that does not affect the commutation relations $\tilde{e}_\lambda \tilde{e}_\mu = C(\lambda, \mu)\tilde{e}_\mu \tilde{e}_\lambda$.

$m \in \mathbb{Z}/5\mathbb{Z}$, and by $T_{m;0}$ a vertex operator associated with a state in $\mathcal{H}^U_m$. Consistency of the OPE implies the fusion rules

$$T_{m;k} \times T_{m';k'} \to T_{m+m';k+k'} \ . \tag{5.70}$$

These rules are preserved by the maps

$$T_{m;k} \mapsto e_\lambda \, T_{m;k} \, e_\lambda^{-1} \ , \qquad \lambda \in \Gamma^{4,4} \ , \tag{5.71}$$

which therefore define symmetries of the orbifold theory. As we have explained above, these symmetries form the extra-special group 5^{1+2}.

Finally, the symmetries (5.21), (5.22), (5.25) and (5.26) of the original torus theory induce a $\mathbb{Z}_4$-group of symmetries of the orbifold. Since $h^{-1}gh = g^{-1}$, the space of g-invariant states of the original torus theory is stabilised by h, so that h restricts to a well-defined transformation on the untwisted sector of the orbifold. Furthermore, h maps the g^k- to the g^{5-k}-twisted sector. Eqs. (5.21) and (5.22) can be written as

$$h(x_1) = 2x_1 + (1-g)(-x_1 - x_2 - x_3 + y_1 + y_2 + y_3 + y_4) \ , \tag{5.72}$$
$$h(y_1) = 2y_1 + (1-g)(-x_1 - x_2 - x_3 - x_4 - 2y_1 - y_2 - y_3 - y_4) \ . \tag{5.73}$$

It follows that the action of h on the operators $e^{(k)}_\lambda$, $k = 1, \ldots, 4$ must be

$$h e^{(k)}_x h^{-1} = e^{(5-k)}_{2x} \ , \qquad h e^{(k)}_y h^{-1} = e^{(5-k)}_{2y} \ , \tag{5.74}$$

and it is easy to verify that this transformation is compatible with (5.68). Correspondingly, the action on the twisted sector ground states is

$$h|m;k\rangle = |3m; 5-k\rangle \ , \tag{5.75}$$

and it is consistent with (5.70).

Thus the full symmetry group is the semi-direct product

$$G = 5^{1+2} : \mathbb{Z}_4 \ , \tag{5.76}$$

where the generator $h \in \mathbb{Z}_4$ maps the central element $\zeta \in 5^{1+2}$ to ζ^{-1}.

All of these symmetries act trivially on the superconformal algebra and on the spectral flow generators, and therefore define symmetries in the sense of the general classification theorem. Indeed, G agrees precisely with the group in case (ii) of the theorem. Thus our orbifold theory realises this possibility.

6 Models with symmetry group containing $3^{1+4} : \mathbb{Z}_2$

Most of the torus orbifold construction described in the previous section generalises to symmetries g of order different than 5. In particular, one can show explicitly that orbifolds of $\mathbb{T}^4$ models by a symmetry g of order 3 contain a group of symmetries $3^{1+4} : \mathbb{Z}_2$, so that they belong to one of the cases (iii) and (iv) of the theorem, as expected from the discussion in section 4.

We take the action of the symmetry g on the left-moving currents and fermionic fields to be of the form (5.9) and (5.11), where ζ is a now a third root of unity; analogous transformations hold for the right-moving fields with respect to a third root of unity $\tilde{\zeta}$. In this case, eq.(5.12) can be satisifed by

$$\zeta = \tilde{\zeta} = e^{\frac{2\pi i}{3}} , \tag{6.1}$$

so that the action is left-right symmetric and g admits an interpretation as a geometric $\mathrm{O}(4,\mathbb{R})$-rotation of order 3 of the torus $\mathbb{T}^4$. For example, the torus $\mathbb{R}^4/(A_2 \oplus A_2)$, where A_2 is the root lattice of the $su(3)$ Lie algebra, with vanishing Kalb-Ramond field, admits such an automorphism.

The orbifold by g contains 6 RR ground states in the untwisted sector. In the k^{th} twisted sector, $k = 1, 2$, the ground states form a representation of an algebra of operators $e^{(k)}_\lambda$, $\lambda \in \Gamma^{4,4}$, satisfying the commutation relations

$$e^{(k)}_\lambda e^{(k)}_\mu = C(\lambda,\mu)^k e^{(k)}_\mu e^{(k)}_\lambda , \tag{6.2}$$

where

$$C(\lambda,\mu) = \zeta^{(P_g(\lambda),\mu)} , \qquad P_g = g + 2g^2 . \tag{6.3}$$

As discussed in section 5.2.2, we can set

$$e^{(k)}_{\lambda+\mu} = e^{(k)}_\mu , \qquad \forall \lambda \in R, \mu \in \Gamma^{4,4} , \tag{6.4}$$

where

$$R = (1-g)\Gamma^{4,4} . \tag{6.5}$$

(Note that $\Gamma^{4,4}$ contains no g-invariant vectors). The main difference with the analysis of section 5.2.2 is that, in this case,

$$\Gamma^{4,4}/R \cong \mathbb{Z}_3^4 . \tag{6.6}$$

In particular, we can find vectors $x_1, x_2, y_1, y_2 \in \Gamma^{4,4}$ such that

$$C(x_i, y_j) = \zeta^{\delta_{ij}} , \qquad C(x_i, x_j) = C(y_i, y_j) = 1 . \tag{6.7}$$

The corresponding operators obey the relations

$$e^{(k)}_{x_i} e^{(k)}_{y_j} = \zeta^{k\delta_{ij}} e^{(k)}_{y_j} e^{(k)}_{x_i} , \quad e^{(k)}_{x_i} e^{(k)}_{x_j} = e^{(k)}_{x_j} e^{(k)}_{x_i} , \quad e^{(k)}_{y_i} e^{(k)}_{y_j} = e^{(k)}_{y_j} e^{(k)}_{y_i} , \tag{6.8}$$

as well as

$$(e^{(k)}_{x_i})^3 = 1 = (e^{(k)}_{y_i})^3 . \tag{6.9}$$

These operators generate the extra-special group 3^{1+4} of exponent 3, and the k^{th}-twisted ground states form a representation of this group. We can choose a basis $|m_1, m_2; k\rangle$, with $m_1, m_2 \in \mathbb{Z}/3\mathbb{Z}$, of simultaneous eigenvectors of $e^{(k)}_{x_1}$ and $e^{(k)}_{x_2}$, so that

$$e^{(k)}_{x_i} |m_1, m_2; k\rangle = \zeta^{m_i} |m_1, m_2; k\rangle , \qquad e^{(k)}_{y_i} |m_1, m_2; k\rangle = |m_1 + k\delta_{1i}, m_2 + k\delta_{2i}; k\rangle . \tag{6.10}$$

The resulting orbifold model has 9 RR ground states in each twisted sector, for a total of $6 + 9 + 9 = 24$ RR ground states, as expected for a K3 model. As in section 5.2.3, the group 3^{1+4} generated by $e_\lambda^{(k)}$ extends to a group of symmetries of the whole orbifold model. Furthermore, the $\mathbb{Z}_2$-symmetry that flips the signs of the coordinates in the original torus theory induces a symmetry h of the orbifold theory, which acts on the twisted sectors by

$$h\,|m_1, m_2; k\rangle = |-m_1, -m_2; k\rangle \ . \tag{6.11}$$

We conclude that the group G of symmetries of any torus orbifold $\mathbb{T}^4/\mathbb{Z}_3$ contains a subgroup $3^{1+4} : \mathbb{Z}_2$, and is therefore included in the cases (iii) or (iv) of the classification theorem. This obviously ties in nicely with the general discussion of section 4.

7 Conclusions

In this paper we have reviewed the current status of the EOT conjecture concerning a possible $\mathbb{M}_{24}$ symmetry appearing in the elliptic genus of K3. We have explained that, in some sense, the EOT conjecture has already been proven since twining genera, satisfying the appropriate modular and integrality properties, have been constructed for all conjugacy classes of $\mathbb{M}_{24}$. However, the analogue of the Monster conformal field theory that would 'explain' the underlying symmetry has not yet been found. In fact, no single K3 sigma-model will be able to achieve this since none of them possesses an automorphism group that contains $\mathbb{M}_{24}$.

Actually, the situation is yet further complicated by the fact that there are K3 sigma-models whose automorphism group is *not even a subgroup of* $\mathbb{M}_{24}$; on the other hand, the elliptic genus of K3 does not show any signs of exhibiting 'Moonshine' with respect to any larger group. As we have explained in this paper, most of the exceptional automorphism groups (i.e. automorphism groups that are not subgroups of $\mathbb{M}_{24}$) appear for K3s that are torus orbifolds. In fact, all cyclic torus orbifolds are necessarily exceptional in this sense, and (cyclic) torus orbifolds account for all incarnations of the cases (ii) – (iv) of the classification theorem of [7] (see section 4). We have checked these predictions by explicitly constructing an asymmetric $\mathbb{Z}_5$ orbifold that realises case (ii) of the theorem (see section 5), and a family of $\mathbb{Z}_3$ orbifolds realising cases (iii) and (iv) of the theorem (see section 6). Incidentally, these constructions also demonstrate that the exceptional cases (ii)-(iv) actually appear in the K3 moduli space — in the analysis of [7] this conclusion relied on some assumption about the regularity of K3 sigma-models.

The main open problem that remains to be understood is why precisely $\mathbb{M}_{24}$ is 'visible' in the elliptic genus of K3, rather than any smaller (or indeed bigger) group. Recently, we have constructed (some of) the twisted twining elliptic genera of K3 [33], i.e. the analogues of Simon Norton's generalised Moonshine functions [34]. We hope that they will help to shed further light on this question.

A Commutation relations in the twisted sector

The vertex operators $V_\lambda(z,\bar z)$ in the g-twisted sector can be defined in terms of formal exponentials of current oscillators

$$E^{\pm}_\lambda(z,\bar z) := \exp\Big(\sum_{\substack{r\in\frac{1}{5}\mathbb{Z}\\ \pm r>0}} (\lambda_L\cdot\alpha)^{(r)}_r \frac{z^{-r}}{r}\Big) \exp\Big(\sum_{\substack{r\in\frac{1}{5}\mathbb{Z}\\ \pm r>0}} (\lambda_R\cdot\tilde\alpha)^{(r)}_r \frac{\bar z^{-r}}{r}\Big)\ , \tag{A.1}$$

where $(\lambda_L\cdot\alpha)^{(r)}_r$ and $(\lambda_R\cdot\tilde\alpha)^{(r)}_r$ are the r-modes of the currents

$$(\lambda_L\cdot\partial X)^{(r)} := \frac{1}{5}\sum_{i=0}^{4}\zeta^{5ir}\lambda_L\cdot g^i(\partial X) = \frac{1}{5}\sum_{i=0}^{4}\zeta^{5ir} g^{-i}(\lambda_L)\cdot\partial X\ , \tag{A.2}$$

$$(\lambda_R\cdot\bar\partial X)^{(r)} := \frac{1}{5}\sum_{i=0}^{4}\bar\zeta^{5ir}\lambda_R\cdot g^i(\bar\partial X) = \frac{1}{5}\sum_{i=0}^{4}\bar\zeta^{5ir} g^{-i}(\lambda_R)\cdot\bar\partial X\ . \tag{A.3}$$

Then we can define

$$V_\lambda(z,\bar z) := E^-_\lambda(z,\bar z)\, E^+_\lambda(z,\bar z)\, e_\lambda\ , \tag{A.4}$$

where the operators e_λ commute with all current oscillators and satisfy

$$e_\lambda\, e_\mu = \epsilon(\lambda,\mu)\, e_{\lambda+\mu}\ , \tag{A.5}$$

for some fifth root of unity $\epsilon(\lambda,\mu)$. The commutator factor

$$C(\lambda,\mu) := \frac{\epsilon(\lambda,\mu)}{\epsilon(\mu,\lambda)}\ , \tag{A.6}$$

can be determined by imposing the locality condition

$$V_\lambda(z_1,\bar z_1)\, V_\mu(z_2,\bar z_2) = V_\mu(z_2,\bar z_2)\, V_\lambda(z_1,\bar z_1)\ . \tag{A.7}$$

To do so, we note that the commutation relations between the operators $E^\pm_\lambda$ can be computed, as in [35], using the Campbell-Baker-Hausdorff formula

$$\begin{aligned} E^+_\lambda(z_1,\bar z_1)E^-_\mu(z_2,\bar z_2) &= E^-_\mu(z_2,\bar z_2)E^+_\lambda(z_1,\bar z_1)\\ &\qquad \prod_{i=0}^{4}[(1-\zeta^{-i}(\tfrac{z_1}{z_2})^{\frac{1}{5}})^{g^i(\lambda)_L\cdot\mu_L}(1-\bar\zeta^{-i}(\tfrac{\bar z_1}{\bar z_2})^{\frac{1}{5}})^{g^i(\lambda)_R\cdot\mu_R}]\ . \end{aligned} \tag{A.8}$$

Using (A.8) and $e_\lambda e_\mu = C(\lambda,\mu)e_\mu e_\lambda$, the locality condition is then equivalent to

$$C(\lambda,\mu)\prod_{i=0}^{4}\frac{(1-\zeta^{-i}(\frac{z_1}{z_2})^{\frac{1}{5}})^{g^i(\lambda)_L\cdot\mu_L}(1-\bar\zeta^{-i}\frac{\bar z_1^{1/5}}{\bar z_2^{1/5}})^{g^i(\lambda)_R\cdot\mu_R}}{(1-\zeta^{i}(\frac{z_2}{z_1})^{\frac{1}{5}})^{g^i(\lambda)_L\cdot\mu_L}(1-\bar\zeta^{i}(\frac{\bar z_2}{\bar z_1})^{\frac{1}{5}})^{g^i(\lambda)_R\cdot\mu_R}} = 1\ , \tag{A.9}$$

that is

$$C(\lambda,\mu)\Big(-\frac{z_1^{1/5}}{z_2^{1/5}}\Big)^{\sum_i g^i(\lambda)_L\cdot\mu_L}\Big(-\frac{\bar z_1^{1/5}}{\bar z_2^{1/5}}\Big)^{\sum_i g^i(\lambda)_R\cdot\mu_R}\prod_{i=0}^{4}[(\zeta^{-i})^{g^i(\lambda)_L\cdot\mu_L}(\bar\zeta^{-i})^{g^i(\lambda)_R\cdot\mu_R}] = 1\ . \tag{A.10}$$

Since $\Gamma^{4,4}$ has no g-invariant vector, we have the identities

$$\sum_{i=0}^{4} g^i(\lambda)_L = 0 = \sum_{i=0}^{4} g^i(\lambda)_R \ , \tag{A.11}$$

and hence finally obtain

$$C(\lambda,\mu) = \prod_{i=0}^{4} (\zeta^i)^{g^i(\lambda_L)\cdot\mu_L - g^i(\lambda_R)\cdot\mu_R} \ . \tag{A.12}$$

Moonshine beyond the monster: The bridge connecting algebra, modular forms and physics, by Terry Gannon, Cambridge Monographs on Mathematical Physics, Cambridge University Press, Cambridge, Massachusetts, 2006, 492 pp., US$130.00, ISBN 978-0-521-83531-2

In about 1972 R. L. Griess and Fischer independently suggested the existence of a new sporadic simple group, which had a double cover of the "baby monster" discovered by Fischer as the centralizer of an involution. Calculations suggested that its smallest non-trivial complex representation probably had dimension 196883. "Moonshine" is the attempt to explain John McKay's extraordinary observation that this number is almost equal to the coefficient 196884 of the elliptic modular function

$$j(\tau) = q^{-1} + 744 + 196884q + 21493760q^2 + \cdots$$

giving the j-invariant of the elliptic curve $\mathbb{C}/\{1, \tau\}$ (where $q = e^{2\pi i\tau}$). At first, a common explanation was that there are many large numbers that turn up in mathematics, and a few of them will be almost equal just by coincidence.

Shortly afterwards, John Thompson [T] pointed out that the next coefficient 21493760 of the elliptic modular function is equal to the sum of the dimensions of the first 3 irreducible representations of the monster, and similarly all the other coefficients seems to be simple linear combinations of dimensions of irreducible representations. He conjectured that this might be because the monster acts on a graded representation V whose piece of degree n is the coefficient of q^n in $j(\tau) - 744$, and suggested looking at the traces of other elements of the monster on this representation. (The coefficient 744 of q^0 is a historical accident as adding an arbitrary constant to j still gives a function with similar properties. The most natural normalization is to set the constant term equal to 24, the number given by Rademacher's infinite series for coefficients of the j function.)

Conway and Norton [CN] carried out Thompson's suggestion and found that the traces of all elements of the monster seem to be given by the coefficients of Hauptmoduls (roughly, functions invariant under a genus 0 congruence subgroup of $SL_2(\mathbb{R})$). Atkin, Fong, and Smith [S] verified that the monster indeed has a representation with these properties by checking that the Hauptmoduls satisfied the necessary congruence and positivity conditions.

The monster simple group was finally constructed by R. L. Griess [G] in 1982. Norton had observed a few years before that the monster probably had a commutative (but non-associative) algebra structure on its 196883 dimensional representation, and it was also known how to write the 196884 dimensional representation as a sum of three irreducible representations of a centralizer of an involution. The monster could therefore be constructed by adjusting the finite number of parameters that an algebra structure depends upon so that the algebra has an extra automorphism. While the idea is simple, the details are horrendous to carry out: John Conway told me that when he heard Griess had constructed the monster, he assumed that Griess must have found another way to do it, because he could not believe that anyone would be patient enough to finish this calculation.

Victor Kac [K] pointed out that the Lie group E_8 has a similar natural infinite dimensional representation, obtained by restricting an irreducible representation of the affine Lie algebra E_8, except that the traces of elements need not be Hauptmoduls but can be more general modular functions. More generally he showed that something similar happens for any highest weight representation of any affine Kac-Moody algebra when restricted to a suitable compact Lie group. Although the monster corresponds to a compact Lie group, no analogue of the corresponding affine Lie algebra is known for it.

Frenkel, Lepowsky, and Meurman [FLM] constructed an infinite dimensional module for the monster. This has the structure of a vertex algebra, and contains the Griess algebra inside it: one of the vertex algebra products is the Griess product. Some of the infinite dimensional representations of affine Lie algebras also carry similar vertex algebra structures, again showing that moonshine for the monster is very closely related to Kac's theory of affine Lie algebras.

The representation constructed by Frenkel, Lepowsky, and Meurman does indeed satisfy the moonshine conjectures; the proof of this uses a "generalized Kac-Moody algebra" acted on by the monster that is constructed using bosonic string theory. There is a small extension of Kac-Moody algebras called generalized Kac-Moody algebras, which unlike Kac-Moody algebras are allowed to have imaginary simple roots. Their theory is very similar: the basic theorems about them were proved by copying out Kac's proofs for the case of Kac-Moody algebras and making the obvious minor changes (though Kac pointed out to me that I introduced some completely original errors). The monster group does not exactly correspond to a Kac-Moody algebra; instead it acts as a group of diagram automorphisms of a generalized Kac-Moody algebra called the monster Lie algebra. The action of the monster group on the monster Lie algebra is similar to the "triality" action of the cyclic group of order 3 acting on the Lie algebra of the orthogonal group in 8 dimensions.

The proof of the moonshine conjecture does not directly show that the McKay-Thompson functions are genus 0. Instead it shows that they are completely replicable; this means that they satisfy identities similar to the product formula for the j-function. At first the fact that the completely replicable functions were Hauptmoduls was verified case by case, but more recently Cummins and Gannon [CG] found a more satisfactory uniform proof of this.

Some sporadic groups in the monster have natural graded representations that have vertex algebra structures only if they are reduced modulo some prime. For example, the baby monster has a representation on a graded space with character

$$q^{-1} + 4372q + 96256q^2 + \cdots$$

which cannot have a natural vertex algebra structure as the piece of dimension 4372 has no non-trivial product invariant under the baby monster. However Ryba [Ry] discovered that it probably does if reduced modulo 2, and in this case the whole space (probably) has a vertex algebra structure over the field with 2 elements invariant under the baby monster. Many, and possibly all, of the finite groups of Lie type also act naturally on vertex algebras over finite fields, which suggests the possibility that all finite simple groups act on suitable vertex algebras. However, for the sporadic groups not involved in the monster, no one has found any evidence of this, except possibly in the case of the Rudvalis group.

Conway and Norton [CNS] also found a particularly elegant presentation for the monster (or rather a closely related group) as a Coxeter group together with one simple extra relation. The fact that this is indeed a presentation for the monster was proved by A. A. Ivanov [I]. The relation between this presentation and the moonshine properties of the monster is unclear, though Miyamoto [M] has made some progress by showing that the generators of the presentation have a reasonably natural description as automorphisms of the monster vertex algebra; his construction uses the Niemeier lattice E_6^4, which makes one wonder if there are similar constructions for the other Niemeier lattices.

Another of McKay's strange observations about E_8 is that orbits of pairs of involutions of type 2A in the monster seem to correspond to the 9 nodes of the affine E_8 diagram. (There is a similar relation between the baby monster and the E_7 diagram, and between the sporadic group Fi_{24} and the E_6 diagram, so this is probably not a coincidence.) Recently Lam and Miyamoto [LM] found certain subalgebras of the monster vertex algebra corresponding to these nodes, which seems to go a long way towards explaining McKay's observation.

The proof of the moonshine conjectures depends on several coincidences. Even the existence of the monster seems to be a fluke in any of the known constructions: these all depend on long, strange calculations that just happen to work for no obvious reason, and would not have been done if the monster had not already been suspected to exist. Then the dimension of the Leech lattice just happens to be just 2 less than the critical dimension 26 of string theory, which is just what is needed for the no-ghost theorem to be used to construct the monster Lie algebra. The monster Lie algebra just happens to have a Weyl vector, which is extremely unusual for algebras constructed like this, and means that its simple roots can be described explicitly.

A major problem with studying the monster vertex algebra is that it is constructed by splicing together two quite different pieces. By analogy, the E_8 is also sometimes constructed as a sum of two pieces: a subalgebra D_8, and a half spin representation S of D_8. The Lie bracket on D_8 is already given, and the bracket of D_8 with S is given by the action of D_8 on S, and the bracket of two elements of S can be given by adjointness, using the fact that S has an invariant bilinear form. The resulting bracket on $D_8 \oplus S$ just happens to satisfy the Jacobi identity, so we get a Lie algebra E_8. The construction of the monster vertex algebra is formally very similar. In the case of E_8 there is a more natural construction which writes the E_8 Lie algebra as just one piece, rather than the sum of two different pieces. For this, one just takes the vertex algebra of (the double cover of) the E_8 lattice; the degree 1 piece of this is the E_8 Lie algebra. (It is not hard to eliminate vertex algebras from this construction and get a completely elementary construction of the E_8 Lie algebra as "one piece".) A major open problem is to find an analogous natural construction of the monster vertex algebra as just one piece, rather than as the sum of several unrelated smaller pieces. Duncan recently managed to do this for a similar superalgebra acted on by the double cover of Conway's simple group: he showed that the vertex superalgebra was isomorphic to the superalgebra of a certain 12 dimensional lattice. Later in [D], he used a similar idea to find a vertex algebra acted on by the Rudvalis groups: this is the first indication that it might be possible to extend moonshine to some of the 6 sporadic groups not involved in the monster.

If a finite group acts on a vertex algebra, then the corresponding "orbifold" vertex algebra is easy to define: it is just the subalgebra fixed by the finite group. However it seems very hard to describe the representations of this subalgebra and the fusion between them, though there has been considerable progress by Dong, Li and Mason [DLM]. If this problem could be solved, it would quickly lead to a solution of the generalized moonshine conjectures, as it would be possible to construct analogues of the monster Lie algebra for all elements of the monster. One way of approaching orbifolds is via nets of von Neumann algebras, which seem to be closely related to vertex algebras: although there seems to be no natural functor going in either direction, whenever there is a construction of an interesting vertex algebra, there seems to be a similar construction of a net of von Neumann algebras, and vice versa. For example, Kawahigashi and Longo [KL] recently gave a construction of a net of von Neumann algebras with automorphism group the monster, by following the usual construction of the monster vertex algebra. For nets of von Neumann algebras, there is a good theory of orbifolds. Unfortunately it is not obvious how to use this to construct the Lie algebras associated to elements of the monster: the problem is that the elements of these Lie algebras correspond to unbounded operators, which are not so easy to get hold of using von Neumann algebras of bounded operators. So vertex algebras see the unbounded operators but cannot handle orbifolds well, while von Neumann algebras can handle orbifolds but cannot see the unbounded operators. Perhaps there is some way to combine vertex algebras and nets that can handle both orbifolds and unbounded operators, and therefore prove the generalized moonshine conjectures.

Hirzeburch [H] has suggested a "prize question" about the existence of a 24 dimensional manifold acted on by the monster, whose cohomology of twisted Dirac operators would give the monster vertex algebra. Hopkins and Mahowald [HM] showed the existence of a manifold with the topological properties suggested by Hirzebruch, though it does not seem to be known whether this manifold has a suitable action of the monster.

The most recent new idea about the monster is Witten's suggestion [W] of a relation between the monster and three dimensional gravity, which I am still too baffled by to say anything useful about.

At the moment we can prove almost anything we want about the monster and moonshine (or could with a bit more effort) but are really short of good explanations for what is going on. For example, there is still no expanation of why the monster exists that does not involve many pages of obscure calculations.

The book under review is a survey of some areas of mathematics related to moonshine. It is written in a lively and readable style, and the author explains what is going on instead of giving formal proofs. Much of the book is only indirectly related to the monster group: for example, there is a long chapter on conformal field theory, and an explanation of the relation between subfactors, knot polynomials, and quantum groups. It is an excellent introduction to this area for anyone who is looking for an informal survey.

One aspect of moonshine that is not discussed much in the present book is the relation between generalized Kac-Moody algebras of rank greater than 2 and automorphic forms of high rank. This is covered in a recent book [Ra] by U. Ray.

O'NAN MOONSHINE AND ARITHMETIC

JOHN F. R. DUNCAN, MICHAEL H. MERTENS, AND KEN ONO

Abstract. Answering a question posed by Conway and Norton in their seminal 1979 paper on moonshine, we prove the existence of a graded infinite-dimensional module for the sporadic simple group of O'Nan, for which the McKay–Thompson series are weight $3/2$ modular forms. The coefficients of these series may be expressed in terms of class numbers, traces of singular moduli, and central critical values of quadratic twists of weight 2 modular L-functions. As a consequence, for primes p dividing the order of the O'Nan group we obtain congruences between O'Nan group character values and class numbers, p-parts of Selmer groups, and Tate–Shafarevich groups of certain elliptic curves. This work represents the first example of moonshine involving arithmetic invariants of this type.

1. Introduction and Statement of Results

The sporadic simple groups are the twenty-six exceptions to the classification [7] of finite simple groups: those examples that aren't included in any of the natural infinite families. It is natural to wonder where they appear, outside of the classification itself.

At least for the *monster*, being the largest of the sporadics, this question has an interesting answer. By the last decade of the last century, Ogg's observation [72] on primes dividing the order of the monster, McKay's famous formula

$$196884 = 1 + 196883,$$

and the much broader family of coincidences observed by Thompson [89, 90] and Conway–Norton [29], were proven by Borcherds [10] to reflect the existence of a certain distinguished algebraic structure. This *moonshine module*, constructed by Frenkel–Lepowsky–Meurman [44, 45, 46], admits a vertex operator algebra structure, has the monster as its full symmetry group, and has modular functions for traces. It is a cornerstone of *monstrous moonshine*, and indicates a pathway by which ideas from theoretical physics, and string theory in particular, may ultimately reveal a natural origin for the monster group and its curious connection to modularity.

In addition to the monster itself, nineteen of the sporadic simple groups appear as quotients of subgroups of the monster. As such, we may expect that monstrous moonshine extends to them in some form. This is consequent upon the *generalized moonshine conjecture*, which was formulated by Norton [71] following preliminary observations of Conway–Norton [29] and Queen [78], and which has been recently proven in powerful work by Carnahan [21].

Certain more general analogues of monstrous moonshine have appeared in this century. In 2010, Eguchi–Ooguri–Tachikawa [41] sparked a resurgence of interest in moonshine with their observation that the elliptic genus of a K3 surface—a trace function arising from a non-linear

---

2010 *Mathematics Subject Classification.* 11F22, 11F37.

sigma model with K3 target—is, essentially, the sum of an indefinite theta function and a q-series whose coefficients are dimensions of modules for Mathieu's largest sporadic group, M_{24}. In fact, this q-series is a mock modular form which, together with most of Ramanujan's mock theta functions, belongs to a family of distinguished examples [24] arising from a family of finite groups. This is *umbral moonshine* [26, 27, 28], and the existence of corresponding umbral moonshine modules has been verified by Gannon [49] in the case of M_{24}, and in general by Griffin and two of the authors of this work [37]. However, it must be noted that this theory is not yet on the same footing as monstrous moonshine, as suitable umbral counterparts to the moonshine module vertex operator algebra of Frenkel–Lepowsky–Meurman are not yet known in general.

We refer the reader to [46, 47] for fuller discussions of monstrous moonshine, and to Gannon's book [48] for a broad perspective on the theory. The more recent review [38] includes some umbral developments. We refer to [75, 76] for new work on the string theoretic interpretation of monstrous moonshine, and refer to [6, 25, 39, 40] for vertex algebraic constructions of some of the umbral moonshine modules.

Very recently, yet another form of moonshine has appeared in work of Harvey–Rayhaun [58] which manifests a kind of half-integral weight counterpart to generalized moonshine for Thompson's sporadic group. This is known as *Thompson moonshine*. The existence of a corresponding module has been confirmed by Griffin and one of the authors [54] (but in this case too, a vertex algebraic realization is yet to be found).

All the umbral groups are involved in the monster in some way, so we are left to wonder if there are counterparts to monstrous moonshine for the remaining six *pariah* sporadic groups: the *Janko groups* J_1, J_3, and J_4, the *Lyons group Ly*, the *Rudvalis group Ru*, and the *O'Nan group O'N*. Can moonshine shed light on these groups too? Conway and Norton asked this question (cf. p. 321 of [29]) in their seminal 1979 paper:

"Finally, we ask whether the sporadic simple groups that may not be involved in [the monster]... have moonshine properties."

This question is also Problem #9 in the 1998 paper by Borcherds entitled "Problems in Moonshine" [12].

Rudvalis group analogues of the moonshine module were constructed in [34, 35], but the physical significance of these structures is yet to be illuminated. In this work we present a new form of moonshine which reveals a role for the O'Nan group in arithmetic: as an organizing object for congruences between class numbers, p-parts of Selmer groups and Tate–Shafarevich groups of elliptic curves. (See e.g. [84] or [88] for background on elliptic curve arithmetic.) This is the first occurrence of moonshine of this type. Since J_1 is a subgroup of $O'N$ it suggests that at least two pariah groups play an active part in some of the deepest open questions in arithmetic.

1.1. **Moonshine and Divisors.** Before describing our results in more detail we offer a conceptual number theoretic perspective which ties together some of the recent developments mentioned above. Suppose that G is one of the finite groups appearing in the aforementioned cases of moonshine. Then we have an infinite-dimensional graded G-module, say V^G, which manifests a collection of modular forms, one for each conjugacy class. For monstrous, umbral, and Thompson moonshine we have

$$V^G = \bigoplus_m V_m^G \xrightarrow{\text{moonshine}} (f_{[g]}) \in \begin{cases} \bigoplus\limits_{[g]\in \mathrm{Conj}(G)} M_0^!(\Gamma_{[g]}) & \text{monstrous} \\ \\ \bigoplus\limits_{[g]\in \mathrm{Conj}(G)} H_{\frac{1}{2}}(\Gamma_{[g]}) & \text{umbral, Thompson.} \end{cases}$$

The defining feature of the $f_{[g]}$ is that their m^{th} coefficients equal the graded traces $\mathrm{tr}(g|V_m^G)$.

In monstrous moonshine, the $f_{[g]}$ are Hauptmoduln for genus 0 groups $\Gamma_{[g]}$ (essentially level $o(g)$ congruence subgroups). At the cusp ∞, they have Fourier expansion

$$f_{[g]} = q^{-1} + O(q)$$

(note $q := e^{2\pi i\tau}$ throughout), and are holomorphic at other cusps. In particular, this means that $\mathrm{div}(f_{[g]}) = cz - \infty$ for some $z \in X(\Gamma_{[g]})$ and some integer c. In contrast, the $f_{[g]}$ in umbral and Thompson moonshine are not functions on modular curves, so it does not generally make sense to consider their divisors. Instead, they are weight $1/2$ harmonic Maass forms (with multiplier) for $\Gamma_{[g]}$, which means that the McKay–Thompson series are generally *mock modular forms*, the holomorphic parts of the $f_{[g]}$. Although they are not functions on these modular curves, it turns out that they actually encode even more information about divisors on $X(\Gamma_{[g]})$. For each discriminant D, there is a map Ψ_D for which

$$V^G = \bigoplus_m V_m^G \xrightarrow{\text{moonshine}} (f_{[g]}) \xrightarrow{\Psi_D} (\Psi_D(f_{[g]})) \in \bigoplus_{[g]\in \mathrm{Conj}(G)} \mathcal{K}(\Gamma_{[g]}),$$

where $\mathcal{K}(\Gamma_{[g]})$ is the field of modular functions for $\Gamma_{[g]}$. The $\Psi_D(f_{[g]})$ are *generalized Borcherds products* as defined by Bruinier and one of the authors [20]. They are meromorphic modular functions with a discriminant D Heegner divisor, and their fields of definition are dictated by the Fourier coefficients of the $f_{[g]}$.

As the preceding discussion illustrates, monstrous, umbral, and Thompson moonshine are (surprising) phenomena in which a single infinite-dimensional graded G-module organizes information about divisors on products of modular curves that are indexed by the conjugacy classes of G. Moreover, the levels of these modular curves are (essentially) the orders of elements in these classes. In the case of monstrous moonshine, the divisors are simple: they are of the form $cz - \infty$. In umbral and Thompson moonshine, we obtain Heegner divisors on $X(\Gamma_{[g]})$.

The appearance of Heegner divisors recalls the seminal work of Zagier [99] on traces of singular moduli on $X_0(1)$. Loosely speaking, Zagier proved that the generating function for such traces in D-aspect can be weight $3/2$ weakly holomorphic modular forms. One of his motivations was to offer a classical perspective on special cases of Borcherds' work [11] on infinite product expansions of modular forms with Heegner divisor.

Although Zagier's paper has inspired too many papers to mention, we highlight an important note by Gross [55]. Gross observed that these types of theorems could be recast in terms of *generalized Jacobians* with cuspidal moduli. In particular, the generalized Jacobian of $X_0(1)$ with respect to the cuspidal divisor $2(\infty)$ is isomorphic to the additive group, and so the sum of the conjugates of Heegner points in the generalized Jacobian is equal to the trace of their modular invariants.

Here we adopt this perspective. Although we do not directly apply these results in this work, our view is that the McKay–Thompson series presented here should be viewed in this way, as generating functions for traces of singular moduli and as functionals on Heegner divisors. This interpretation is an extension of the celebrated theorem of Gross–Kohnen–Zagier [56] which asserts that the generating function for Heegner divisors on $X_0(N)$ are weight 3/2 cusp forms with values in the Jacobian of $X_0(N)$. By work of Waldspurger [93, 94] this earlier theorem can be thought of as a result on central critical values of quadratic twists of weight 2 modular L-functions.

1.2. **Main Results.** In view of these developments, it is natural to seek weight 3/2 moonshine. One can loosely think of this as the moonshine obtained by summing weight 1/2 moonshine in D-aspect (e.g. umbral and Thompson moonshine), where the resulting McKay–Thompson series are generating functions for the arithmetic of Heegner divisors. Namely, we seek moonshine of the form

$$V^G = \bigoplus_m V_m^G \quad \xrightarrow{\text{moonshine}} \quad (f_{[g]}) \in \bigoplus_{[g]\in\mathrm{Conj}(G)} H_{\frac{3}{2}}(\Gamma_{[g]}) \otimes \mathrm{Jac}(X(\Gamma_{[g]})),$$

where $\mathrm{Jac}(X(\Gamma_{[g]})$ denotes a suitable generalized Jacobian of $X(\Gamma_{[g]})$. In such moonshine, the $f_{[g]}$ will be generating functions for suitable functionals over Heegner divisors. Their coefficients will be sums of class numbers, traces of singular moduli, and square-roots of central critical values of L-functions of quadratic twists of weight 2 modular forms.

Here we establish the first example of moonshine of this type, and it is pleasing that pariah sporadic groups appear. We prove moonshine for the O'Nan group *O'N*, a group discovered in 1973 as part of the flurry of activity related to the classification of finite simple groups [73] and shown not to be involved in the monster by Griess [52, Lemma 14.5]. This group was first constructed by Sims (cf. [73, p. 421]), and Ryba [81] later gave an alternative construction. It has order $\#O'N = 2^9\cdot 3^4\cdot 5\cdot 7^3\cdot 11\cdot 19\cdot 31$, and it has 30 conjugacy classes. It contains the first Janko group J_1, also not involved in the monster [95], as a subgroup.

Theorem 1.1. *There is an infinite-dimensional virtual graded O'N-module*

$$W := \bigoplus_{0<m\equiv 0,3 \pmod 4} W_m$$

and weight 3/2 modular forms $\{F_{1A}, F_{2A}, \ldots, F_{31A}, F_{31B}\}$*, one for each conjugacy class, with the property that*

$$F_{[g]}(\tau) = -q^{-4} + 2 + \sum_{0<m\equiv 0,3 \pmod 4} \mathrm{tr}(g|W_m)q^m.$$

Moreover, each $F_{[g]}$ *is on the group* $\Gamma_0(4o(g))$*, with a non-trivial character in case* $o(g) = 16$*, and satisfies the Kohnen plus space condition.*

Remark. There is an alternative to Theorem 1.1 in which the $F_{[g]}$ have trivial characters for all g, but are mock modular for $o(g) = 16$. That formulation featured in an earlier version of this work. The present statement is motivated by cohomological considerations and related structures in the representation theory of vertex operator algebras, as we explain in more detail in Section 3. We also characterize the $F_{[g]}$ precisely in Section 3.

Remark. In other prominent examples of moonshine (e.g. monstrous [29] and umbral [26, 27] moonshine) the McKay–Thompson series of a group element g is a modular form (essentially) of level $o(g)$, but in this work the McKay–Thompson series $F_{[g]}$ have level $4o(g)$. This anomaly can be resolved by repackaging the $F_{[g]}$ as Jacobi forms as follows. For $g \in O'N$ set

$$\varphi_{[g]}(\tau, z) := F_{[g],0}(\tfrac{\tau}{4})\theta_{1,0}(\tau, z) + F_{[g],1}(\tfrac{\tau}{4})\theta_{1,1}(\tau, z) \tag{1.1}$$

where $F_{[g],r}(\tau) := \sum_{m\equiv r \bmod 2} \operatorname{tr}(g|W_m)q^m$ and $\theta_{1,r}(\tau, z) := \sum_{n\equiv r \bmod 2} e^{2\pi i n z} q^{\frac{n^2}{4}}$. Then $\varphi_{[g]}$ is a weakly holomorphic Jacobi form of weight 2 and index 1 on $\Gamma_0(o(g))$, with a non-trivial character in case $o(g) = 16$. For the sake of simplicity we have chosen to formulate our results in terms of the scalar-valued modular forms $F_{[g]}$ in this work. However, we note that one advantage of the Jacobi form formulation is that it illuminates an analogue of the Hauptmodul property of monstrous moonshine. Namely, each $\varphi_{[g]}$ has the property that it is uniquely determined, up to a cusp form, by the condition that it has growth of a certain form (independent of g) near the infinite cusp of $\Gamma_0(o(g))$, and vanishes at all other cusps. This follows from the proof of Theorem 3.1. It may be compared to monstrous moonshine, in which the McKay–Thompson series are uniquely determined up to constant functions by an analogous condition, and to umbral and Thompson moonshine, in which the McKay–Thompson series are uniquely determined by such a condition up to theta series (although in the umbral case almost all the relevant spaces of theta series vanish; cf. [28]). It is the appearance of cusp forms that allows us to connect the O'Nan group to elliptic curve arithmetic.

Remark. The module W is *virtual* in the sense that some irreducible representations of $O'N$ occur with negative multiplicity in W_m for some m. The proof of Theorem 1.1 will show that only non-negative multiplicities appear for $m \notin \{7, 8, 12, 16\}$. So in fact we can replace W with a non-virtual module for a small cost, by adding suitable multiples of weight 3/2 unary theta functions (i.e. sums of the form $\sum_{n\in\mathbb{Z}} n\epsilon(n)q^{\lambda n^2}$ where ϵ is an odd periodic function and λ is a positive rational) to the McKay–Thompson series $F_{[g]}$. This changes the module structure of W_m when $m = vd^2$ for $v \in \{7, 8, 12, 16\}$, for certain integers d, but it does not effect the validity of our other three main results, Theorems 1.2, 1.3, and 1.4, for $-D < -16$. The price for such an adjustment to W is the property that the McKay–Thompson series attached to $[g]$ have level $4o(g)$. It is this property which motivates us to focus on the particular module W that appears in Theorem 1.1.

The $F_{[g]}$ will turn out to be expressible in terms of traces of singular moduli for Hauptmoduln (cf. Section 5), class numbers, and central critical L-values of quadratic twists of weight 2 modular forms (cf. Section 4.2.2). The Hauptmoduln which arise are for the genus 0 modular curves

$$\{X_0(N) : N = 1, \dots, 8, 10, 12, 16\} \cup \{X_0^+(N) : N = 11, 14, 15, 16, 19, 20, 28, 31, 32\}, \tag{1.2}$$

where $X_0^+(N)$ is the modular curve corresponding to the extension of $\Gamma_0(N)$ by all the level N Atkin–Lehner involutions.

Remark. Purely for the sake of curiosity we mention that it follows from the description of the dimensions of the graded components W_m in terms of traces of singular moduli (cf. Appendix D) that

$$\dim W_{163} = \frac{1}{2}(\alpha^2 + \alpha - 393768),$$

where

$$\alpha = \left\lceil e^{\pi\sqrt{163}} \right\rceil = \lceil 262537412640768743.99999999999250072... \rceil$$

denotes the Ramanujan constant. (This number was actually already discovered and studied by Hermite in 1859 [59].)

Remark. From Tables B.1 to B.3 we see that W_3 is an irreducible *O'N*-module of dimension 26752, and W_4 has three irreducible constituents, with dimensions 1, 58311 and 85064. On the other hand the specialization $\varphi_{1A}(\tau, 0)$ of Equation (1.1) is the derivative of the J function, up to a scalar factor. This leads to the identity

$$196884 = 5 \cdot 1 + 2 \cdot 26752 + 58311 + 85064,$$

where the summands on the right are dimensions of irreducible representations of *O'N*. Inspired by the moonshine module vertex operator algebra [46] of Frenkel–Lepowsky–Meurman we may ask: is there a holomorphic vertex operator algebra with an action by *O'N* that explains this coincidence? (See the second remark in Section 3 for some further related comments.)

Armed with Theorem 1.1 and the explicit identities expressing the $F_{[g]}$ in terms of singular moduli, class numbers and critical L-values, it is natural to ask whether the infinite-dimensional *O'N*-module W reveals arithmetic information about the modular curves they organize, which include the positive genus curves

$$\{X_0(11),\ X_0(14),\ X_0(15),\ X_0(19),\ X_0(20),\ X_0(28),\ X_0(31)\}$$

related to the $X_0^+(N)$ in (1.2). For example, are there interesting congruences modulo primes $p|\#O'N$ which relate the graded components W_m to classical objects in number theory and arithmetic geometry? This is indeed the case, and we now describe surprising congruences which relate graded dimensions and traces of W to class numbers and Selmer groups and Tate–Shafarevich groups of elliptic curves.

Remark. Suppose that p is prime and g_n (resp. g_{np}) are elements of *O'N* with order n (resp. np). Then by Theorem 1.1, we have that $\operatorname{tr}(g_n|W_m) \equiv \operatorname{tr}(g_{np}|W_m) \pmod{p}$ for all m. In particular, if $o(g) = p$, then for all m we have

$$\dim W_m \equiv \operatorname{tr}(g|W_m) \pmod{p}.$$

The following theorem concerns congruences modulo small primes p and ideal class groups of imaginary quadratic fields. Here and in the following, we denote by $H(D)$ the Hurwitz class number of positive definite binary quadratic forms of discriminant $-D < 0$ (cf. Section 5).

Theorem 1.2. *Suppose that $-D < 0$ is a fundamental discriminant. Then the following are true:*

(1) *If* $-D < -8$ *is even and* $g_2 \in O'N$ *has order 2, then*

$$\dim W_D \equiv \operatorname{tr}(g_2|W_D) \equiv -24H(D) \equiv 0 \pmod{2^4}.$$

(2) *If* $p \in \{3, 5, 7\}$, $\left(\frac{-D}{p}\right) = -1$ *and* $g_p \in O'N$ *has order* p, *then*

$$\dim W_D \equiv \operatorname{tr}(g_p|W_D) \equiv \begin{cases} -24H(D) \pmod{3^2} & \text{if } p = 3, \\ -24H(D) \pmod{p} & \text{if } p = 5, 7. \end{cases}$$

Remark. Systematic congruences which assert for $\left(\frac{-D}{p}\right) = -1$ that

$$\dim W_D \equiv -24H(D) \pmod{p}$$

do not seem to hold for $p \geq 17$. However, this congruence holds for $p = 13$, a bonus because $13 \nmid \#O'N$.

Remark. As the proof of Theorem 1.2 will reveal, it holds true that if $-D < -8$ is an even fundamental discriminant, then $H(D)$ is even, and $\dim W_D \equiv 0 \pmod{2^4}$.

In view of Theorem 1.2, it is natural to consider the primes $p = 11, 19$ and 31 which also divide $\#O'N$. For these primes, a refinement of the congruences above is necessary. In particular, for the primes 11 and 19 we obtain congruences which relate $\dim W_D$ to Selmer groups and Tate–Shafarevich groups of elliptic curves (cf. [84, Chapter X]).

Let $E/\mathbb{Q}$ be an elliptic curve given by

$$E: \quad y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$$

where $a_1, a_2, a_3, a_4, a_6 \in \mathbb{Z}$. For a fundamental discriminant D, let $E(D)$ denote its D-quadratic twist, and let $\operatorname{rk}(E(D))$ denote the Mordell–Weil rank of $E(D)$ over $\mathbb{Q}$. The $O'N$-module W encodes deep information about the Selmer and Tate–Shafarevich groups of the quadratic twists of elliptic curves with conductor 11, 14, 15, and 19. To make this precise, suppose that ℓ is an odd prime. Then for each curve $E(D)$ we have the short exact sequence

$$1 \to E(D)/\ell E(D) \to \operatorname{Sel}(E(D))[\ell] \to Ш(E(D))[\ell] \to 1,$$

where $\operatorname{Sel}(E(D))[\ell]$ is the ℓ-Selmer group of $E(D)$, and $Ш(E(D))[\ell]$ denotes the elements of the Tate–Shafarevich group $Ш(E(D))$ with order dividing ℓ.

For $p = 11$ and 19, we let $E_p/\mathbb{Q}$ be the $\Gamma_0(p)$-optimal elliptic curves given by the Weierstrass models

$$E_{11}: \quad y^2 + y = x^3 - x^2 - 10x - 20,$$
$$E_{19}: \quad y^2 + y = x^3 + x^2 - 9x - 15$$

(cf. [68, Elliptic Curve 11.a2, Elliptic Curve 19.a2]). We obtain the following congruence relating the graded dimension $\dim W_D$ to class numbers, and Selmer groups and Tate–Shafarevich groups of such twists.

Theorem 1.3. *Assume the Birch and Swinnerton-Dyer Conjecture. If* $p = 11$ *or* 19 *and* $-D < 0$ *is a fundamental discriminant for which* $\left(\frac{-D}{p}\right) = -1$, *and* $g_p \in O'N$ *has order* p, *then the following are true.*

(1) We have that $\mathrm{Sel}(E_p(-D))[p] \neq \{0\}$ *if and only if*

$$\dim W_D \equiv \mathrm{tr}(g_p|W_D) \equiv -24H(D) \pmod{p}.$$

(2) Suppose that $L(E_p(-D),1) \neq 0$. *Then we have that* $\mathrm{rk}(E(-D)) = 0$. *Moreover, we have* $p|\#\text{Ш}(E_p(-D))$ *if and only if*

$$\dim W_D \equiv \mathrm{tr}(g_p|W_D) \equiv -24H(D) \pmod{p}.$$

Remark. The claim about ranks in Theorem 1.3 (2) is unconditional thanks to the work of Kolyvagin [67].

Remark. By Goldfeld's famous conjecture on ranks of quadratic twists of elliptic curves [51], it turns out that the hypothesis in Theorem 1.3 (2) is expected to hold for 100% of the $-D$ for which $\left(\frac{-D}{p}\right) = -1$. Therefore, for almost all such $-D$, we should have a test for determining the presence of order p elements in these Tate–Shafarevich groups.

Remark. There is a more complicated congruence for the prime $p = 31$. For fundamental discriminants $-D < 0$ satisfying $\left(\frac{-D}{31}\right) = -1$, we have that $\dim W_D \equiv \mathrm{tr}(g_{31}|W_D) \pmod{31}$ are related to the central critical values of the $-D$ twists of the L-function for the genus 2 curve

$$C: \quad y^2 + (x^3+x+1)y = x^5 + x^4 + x^3 - x - 1$$

(cf. [68, Genus 2 Curve 961.a.961.3]). Its L-function arises from the two newforms in $S_2(\Gamma_0(31))$ which are Galois conjugates. Namely, if $\phi := \frac{1+\sqrt{5}}{2}$ then the two newforms are f^σ and

$$f(\tau) := \sum_{n=1}^{\infty} a(n)q^n = q + \phi q^2 - 2\phi q^3 + (\phi-1)q^4 + q^5 - (2\phi+2)q^6 + O(q^7),$$

where $\sigma(\sqrt{5}) = -\sqrt{5}$. If $p \nmid 31$ is prime, then the local L-factor $L_p(T)$ at p is

$$L_p(T) := (1 - a(p)T + pT^2)(1 - \sigma(a(p))T + pT^2).$$

Remark. Apart from the claims about $\mathrm{tr}(g_{17}|W_D)$ (there are no elements of order 17 in $O'N$), Theorem 1.3 holds for $p = 17$ as well. Namely, the congruences hold for E_{17}, the optimal $\Gamma_0(17)$ elliptic curve over $\mathbb{Q}$ (cf. [68, Elliptic Curve 17.a3]) given by

$$E_{17}: \quad y^2 + xy + y = x^3 - x^2 - x - 14.$$

The two theorems on congruences above only pertain to the dimensions of the graded components of the $O'N$-module W. We now turn to congruences for graded traces for elements of order 2 and 3. To this end, we let E_{14} and E_{15} be the corresponding optimal elliptic curves over $\mathbb{Q}$ (cf. see [68, Elliptic Curve 14.a6, Elliptic Curve 15.a5]) given by

$$E_{14}: \quad y^2 + xy + y = x^3 + 4x - 6,$$
$$E_{15}: \quad y^2 + xy + y = x^3 + x^2 - 10x - 10.$$

Using work of Skinner and Skinner–Urban [85, 86] related to the Iwasawa main conjectures for GL_2, we obtain the following unconditional result.

Theorem 1.4. *Assume the notation above, and suppose that* $N \in \{14, 15\}$*. If* p *is the unique prime* ≥ 5 *dividing* N*, then let* $\delta_p := \frac{p-1}{2}$ *and let* $p' := N/p$*. If* $-D < 0$ *is a fundamental discriminant for which* $\left(\frac{-D}{p}\right) = -1$ *and* $\left(\frac{-D}{p'}\right) = 1$*, then the following are true.*

(1) We have that $\mathrm{Sel}(E_N(-D))[p] \neq \{0\}$ *if and only if*

$$\mathrm{tr}(g_{p'}|W_D) \equiv \mathrm{tr}(g_N|W_D) \equiv \delta_p \cdot (H(D) - \delta_p H^{(p')}(D)) \pmod{p}.$$

(2) Suppose that $L(E_N(-D), 1) \neq 0$*. Then we have that* $\mathrm{rk}(E(-D)) = 0$*. Moreover, we have* $p|\#\text{Ш}(E_N(-D))$ *if and only if*

$$\mathrm{tr}(g_{p'}|W_D) \equiv \mathrm{tr}(g_N|W_D) \equiv \delta_p \cdot (H(D) - \delta_p H^{(p')}(D)) \pmod{p}.$$

Remark. We note that Theorem 1.4 does not apply for $p = 2$ (resp. $p = 3$) when $N = 14$ (resp. $N = 15$). In the case of $p = 2$ the work of Skinner–Urban does not apply. For $p = 3$ the connection between graded traces and central values of Hasse-Weil L-functions does not hold. Namely, a critical hypothesis due to Kohnen in terms of eigenvalues of Atkin–Lehner involutions fails (cf. Proposition 4.4).

Remark. In view of the new results presented here, it is natural to wonder where one should look for further moonshine. It seems likely that other sporadic groups will fall within the scope of weight $3/2$ moonshine. In another direction, one can ask about other half-integral weights. Also, it is natural to wonder if there are extensions of moonshine to Shimura curves and varieties. Are there infinite-dimensional G-modules which organize the arithmetic of their divisors?

1.3. **Methods.**

To prove Theorem 1.1, we employ the theory of Rademacher sums, harmonic Maass forms, and standard facts about the representation theory of finite groups. Namely, we make use of the character table of *O'N* (cf. Table A.1), and the Schur orthogonality relations for group characters. In Section 2, we first recall essential facts about harmonic Maass forms and Rademacher sums. In Section 3, we prove a theorem which, using harmonic Maass forms, explicitly constructs weakly holomorphic weight $3/2$ modular forms, one for each conjugacy class of *O'N*. Furthermore, we establish that these modular forms have integer Fourier coefficients. To complete the proof, we apply the Schur orthogonality relations to these functions to construct weight $3/2$ modular forms whose coefficients encode the multiplicities of the irreducibles of the graded components of the alleged module W. The proof is complete once it is established that these multiplicities are integral. Since the obstruction to integrality is bounded by group theoretical considerations, the proof of integrality follows by confirming sufficiently many congruence relations among these forms. These calculations confirm that W is a virtual module. However, as mentioned earlier, it turns out that the multiplicities of each irreducible are non-negative in W_m once $m > 16$. This claim follows from an analytic argument which involves bounding sums of Kloosterman sums. These statements are proved in Section 4. In Section 5 we recall properties of singular moduli, and we interpret the modular forms number theoretically in terms of singular moduli and class numbers and cusp forms. We prove Theorems 1.2, 1.3 and 1.4 in Section 6. These proofs require the explicit formulas for the $F_{[g]}$, the results in Section 5, and the work of Skinner–Urban on the Birch and Swinnerton-Dyer Conjecture. We conclude the paper in Section 7 with numerical examples of some of these results.

Acknowledgements

The authors thank Kathrin Bringmann, Michael Griffin, Dick Gross, Maryam Khaqan, Winfried Kohnen, Martin Raum, Jeremy Rouse, Jean-Pierre Serre and anonymous referees for helpful comments and corrections. The authors thank Theo Johnson-Freyd for communication regarding his joint work with David Treumann on the cohomology of the O'Nan group. The authors thank Drew Sutherland for computing the elliptic curve invariants in Tables 7.5 and 7.6.

2. Rademacher Sums and Harmonic Maass Forms

Harmonic Maass forms are now a central topic in number theory. Their study originates from the work of Bruinier–Funke [18] on geometric theta lifts and Zwegers' seminal work [101] on Ramanujan's mock theta functions. These realizations played a central role in the work of Bringmann and one of the authors on the Andrews–Dragonette Conjecture and Dyson's partition ranks [15, 17]. For an overview on the subject of harmonic Maass forms and its applications in number theory and various other fields of mathematics, including mathematical physics, we refer the reader to [14, 31, 74, 100].

Here, we briefly recall the essential facts about harmonic Maass forms that are required in this paper. Namely, we recall Rademacher sums, and we describe their projection to Kohnen's plus space.

2.1. **Rademacher Sums.** Here and throughout, we let $\tau = u + iv$, $u, v \in \mathbb{R}$, denote a variable in the upper half-plane $\mathfrak{H}$ and we use the shorthand $e(\alpha) := e^{2\pi i \alpha}$.

Definition 2.1. *We call a smooth function $f : \mathfrak{H} \to \mathbb{C}$ a harmonic Maass form of* weight $k \in \frac{1}{2}\mathbb{Z}$ *and* level N *if the following conditions are satisfied:*

(1) *We have $f|_k\gamma(\tau) = f(\tau)$ for all $\gamma \in \Gamma_0(N)$ and $\tau \in \mathfrak{H}$, where we define*

$$f|_k\gamma(\tau) := \begin{cases} (c\tau+d)^{-k} f\left(\frac{a\tau+b}{c\tau+d}\right) & \text{if } k \in \mathbb{Z} \\ \left(\left(\frac{c}{d}\right)\varepsilon_d\right)^{2k} \left(\sqrt{c\tau+d}\right)^{-2k} f\left(\frac{a\tau+b}{c\tau+d}\right) & \text{if } k \in \frac{1}{2}+\mathbb{Z}. \end{cases}$$

with

$$\varepsilon_d := \begin{cases} 1 & \text{if } d \equiv 1 \pmod 4, \\ i & \text{if } d \equiv 3 \pmod 4. \end{cases}$$

and where we assume $4|N$ if $k \notin \mathbb{Z}$.

(2) *The function f is annihilated by the* weight k hyperbolic Laplacian,

$$\Delta_k f := \left[-v^2\left(\frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2}\right) + ikv\left(\frac{\partial}{\partial u} + i\frac{\partial}{\partial v}\right)\right] f \equiv 0.$$

(3) *There is a polynomial $P(q^{-1})$ such that $f(\tau) - P(e^{-2\pi i\tau}) = O(v^c)$ for some $c \in \mathbb{R}$ as $v \to \infty$. Analogous conditions are required at all cusps of $\Gamma_0(N)$.*

We denote the space of harmonic Maass forms of weight k and level N by $H_k(\Gamma_0(N))$.

Remark. We note that condition (3) in the definition above differs from other definitions which occur commonly in the literature. For example, *harmonic Maass forms with principal parts* are those forms for which the $O(v^c)$ bound is replaced by $O(e^{-cv})$ for $c > 0$. Namely, the harmonic Maass forms we consider here are permitted to have 0^{th} Fourier coefficients which are essentially powers of v.

For the basic properties of these functions, we again refer to the literature mentioned above. We mention however the following lemmas.

Lemma 2.2. *Let $f \in H_k(\Gamma_0(N))$ be a harmonic Maass form of weight $k \neq 1$. Then there is a canonical splitting*

$$f(\tau) = f^+(\tau) + f^-(\tau), \tag{2.1}$$

where for some $m_0 \in \mathbb{Z}$ we have the Fourier expansions

$$f^+(\tau) := \sum_{n=m_0}^{\infty} c_f^+(n) q^n,$$

and

$$f^-(\tau) := \overline{c_f^-(0)} \frac{(4\pi v)^{1-k}}{k-1} + \sum_{n=1}^{\infty} \overline{c_f^-(n)} n^{k-1} \Gamma(1-k; 4\pi n v) q^{-n},$$

where

$$\Gamma(\alpha; x) := \int_x^{\infty} t^{\alpha} e^{-t} \frac{dt}{t}$$

denotes the usual incomplete gamma function.

The q-series f^+ in (2.1) is called the *holomorphic part* of the harmonic Maass form f.

An important differential operator in the theory of harmonic Maass forms is the ξ-operator, a variation of the Maass lowering operator.

Proposition 2.3. *The operator*

$$\xi_k : H_k(\Gamma_0(N)) \to M_{2-k}(\Gamma_0(N)),\ f \mapsto \xi_k(f) := 2iy^k \overline{\frac{\partial f}{\partial \overline{\tau}}}$$

is a well-defined and surjective anti-linear map with kernel $M_k^!(\Gamma_0(N))$.

Mock modular forms are the holomorphic parts of harmonic Maass forms. Any mock modular form has an associated modular form, called its *shadow*, which is the image of its corresponding harmonic Maass form under the ξ-operator. A mock modular form with vanishing shadow is a (weakly holomorphic) modular form.

The next lemma seems to have been missed by the literature.

Lemma 2.4. *A harmonic Maass form whose holomorphic part vanishes at all cusps is a (holomorphic) cusp form.*

Proof. This is a direct consequence of the properties of the Bruinier–Funke pairing (cf. Proposition 3.5 in [18]). □

A convenient way to construct mock modular forms, which are holomorphic parts of harmonic Maass forms, is through *Rademacher sums*. These were introduced by Rademacher in his work on coefficients of the J-function [79], and further developed in the context of moonshine mainly by Cheng, Frenkel and one of the authors [22, 23, 36].

Rademacher sums can be thought of as low weight analogues of Poincaré series. For a fixed level N and some $K > 0$, we define the set

$$\Gamma_{K,K^2}(N) := \left\{ \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N) \; : \; |c| < K \text{ and } |d| < K^2 \right\}.$$

Given an integer μ we can use this to formally define the Rademacher sum

$$R^{[\mu]}_{k,N}(\tau) := \lim_{K\to\infty} \sum_{\gamma\in\Gamma_\infty\backslash\Gamma_{K,K^2}(N)} q^\mu|_k\gamma$$

where as usual $\Gamma_\infty := \{\pm \left(\begin{smallmatrix} 1 & n \\ 0 & 1 \end{smallmatrix}\right) \; : \; n \in \mathbb{Z}\}$ denotes the stabilizer of ∞ in $\Gamma_0(N)$. If convergent, these sums define mock modular forms of the indicated weight, level and character. Convergence for these series however is in general a delicate matter when the weight k is between 0 and 2. We will be interested in these series when the weight is $k = \frac{3}{2}$ in which case it has been established in [22, Section 5] that they do converge (possibly using a certain regularization explained in loc. cit.) and define holomorphic functions on $\mathfrak{H}$.

By construction, Rademacher sums are 1-periodic and therefore have a Fourier expansion. It is given in terms of infinite sums of *Kloosterman sums*

$$K_k(m,n,c) := \sum_{d \pmod c}^{*} \left(\frac{c}{d}\right) \varepsilon_d^{2k} e\left(\frac{m\overline{d}+nd}{c}\right) \tag{2.2}$$

weighted by Bessel functions. Here we have that $k \in \frac{1}{2} + \mathbb{Z}$, c is divisible by 4, the * at the sum indicates that it runs over primitive residue classes modulo c, and $\overline{d}$ denotes the multiplicative inverse of d modulo c. Computing the Fourier expansion of a Rademacher sum is a standard computation, see for instance [23, Section 3.1] and [74, Section 8.3].

Theorem 2.5. *Assuming locally uniform convergence, for $\mu \leq 0$ and $k \in \frac{1}{2}+\mathbb{N}$ and $4|N$, the Rademacher sum $R^{[\mu]}_{k,N}$ defines a mock modular form of weight k for $\Gamma_0(N)$ whose shadow is given by a constant multiple of the Rademacher sum $R^{[-\mu]}_{2-k,N}$. Its Fourier expansion is given by*

$$R^{[\mu]}_{k,N}(\tau) = q^\mu + \sum_{n=1}^{\infty} c^{[\mu]}_{k,N}(n) q^n,$$

where

$$c^{[\mu]}_{k,N}(n) = -2\pi i^k \left|\frac{n}{\mu}\right|^{\frac{k-1}{2}} \sum_{\substack{c>0 \\ c\equiv 0 \pmod N}} \frac{K_k(\mu,n,c)}{c} \cdot I_{k-1}\left(\frac{4\pi\sqrt{|\mu n|}}{c}\right) \tag{2.3}$$

for $\mu < 0$ and

$$c^{[0]}_{k,N}(n) = (-2\pi i)^k \frac{n^{k-1}}{\Gamma(k)} \sum_{\substack{c>0 \\ c\equiv 0 \pmod N}} \frac{K_k(0,n,c)}{c^k}. \tag{2.4}$$

The completion $\widehat{R^{[\mu]}_{k,N}}$ of $R^{[\mu]}_{k,N}$ to a harmonic Maass form has a pole of order μ at the cusp ∞ and vanishes at all other cusps.

Remark. One can also consider Rademacher sums of weights $\leq 1/2$, which are the main subject of [22] and play a crucial rule in both umbral and Thompson moonshine. The formulas look very similar in those cases, but since they are not needed, we omit them here.

2.2. **Kohnen's Plus Space.** In [66], Kohnen introduced the notion of the so-called plus space, a natural subspace of weight $k + \frac{1}{2}$ cusp forms for $\Gamma_0(4N)$ which is isomorphic via the Shimura correspondence to the space of weight $2k$ cusp forms of level N as a Hecke module, provided that N is odd and square-free. This space is easily characterized via Fourier expansions. Namely, it consists of all forms in $S_{k+\frac{1}{2}}(\Gamma_0(4N))$ (or, by extension, $M^!_{k+\frac{1}{2}}(\Gamma_0(4N))$ and also $H_{k+\frac{1}{2}}(\Gamma_0(4N))$) whose Fourier coefficients are supported on exponents n with $n \equiv 0, (-1)^k \pmod 4$. There is a natural projection operator

$$| \operatorname{pr} : S_{k+\frac{1}{2}}(\Gamma_0(4N)) \to S^+_{k+\frac{1}{2}}(\Gamma_0(4N))$$

for N odd given in terms of slash operators (see loc. cit.), which extends to spaces of weakly holomorphic modular forms and harmonic Maass forms. The action of this projection operator on principal parts of harmonic Maass forms is described in the following lemma (cf. Lemma 2.9 in [54]).

Lemma 2.6. *Let N be odd and let $f \in H_{k+\frac{1}{2}}(\Gamma_0(4N))$ for some $k \in \mathbb{N}_0$. Suppose that*

$$f^+(\tau) = q^{-m} + \sum_{n=0}^{\infty} a_n q^n$$

for some $m > 0$ with $-m \equiv 0, (-1)^k \pmod 4$, and suppose also that f has a non-vanishing principal part only at the cusp ∞ and is bounded at the other cusps of $\Gamma_0(4N)$. Then the projection $f|\operatorname{pr}$ of f to the plus space has a pole of order m at ∞ and has a pole of order $\frac{m}{4}$ either at the cusp $\frac{1}{N}$ if $m \equiv 0 \pmod 4$, or at the cusp $\frac{1}{2N}$ if $-m \equiv (-1)^k \pmod 4$, and is bounded at all other cusps.

For the purpose of this paper, we are particularly interested in the Fourier expansions of weight 3/2 Rademacher sums projected to the plus space (see the following section). Convergence for these follows along the same lines as in [22, Section 5]. The following proposition gives their Fourier expansion explicitly.

Proposition 2.7. *Consider the Rademacher sum $R^{[\mu]}_{\frac{3}{2},4N}$ for $\mu \leq 0$ such that $\mu \equiv 0, 3 \pmod 4$ and N odd. Then we have that*

$$R^{[\mu],+}_{\frac{3}{2},4N}(\tau) := \left(R^{[\mu]}_{\frac{3}{2},4N}|\operatorname{pr}\right)(\tau) = q^{\mu} + \sum_{\substack{n>0 \\ n \equiv 0,3 \pmod 4}} c^{[\mu],+}_{\frac{3}{2},4N}(n) q^n,$$

where we have

$$c^{[\mu],+}_{\frac{3}{2},4N}(n) = \kappa(\mu, n) \sum_{c=1}^{\infty} \left(1 + \delta_{odd}(Nc)\right) K_{\frac{3}{2}}(\mu, n, 4Nc) \cdot \mathcal{I}(\mu, n, 4Nc), \tag{2.5}$$

with

$$\kappa(\mu,n) := \begin{cases} 2\pi e\left(-\frac{3}{8}\right) & \textit{if } \mu=0,\\ 2\pi e\left(-\frac{3}{8}\right)(n/|\mu|)^{\frac{1}{4}} & \textit{otherwise,}\end{cases} \tag{2.6}$$

$$\delta_{odd}(n) := \begin{cases} 1 & \textit{if } n \textit{ is odd,}\\ 0 & \textit{otherwise,}\end{cases} \tag{2.7}$$

and

$$\mathcal{I}(\mu,n,c) := \begin{cases} \dfrac{(2\pi n)^{\frac{1}{2}}}{c^{\frac{3}{2}}\Gamma(3/2)} & \textit{if } \mu=0,\\ \\ \dfrac{I_{\frac{1}{2}}\left(\frac{4\pi\sqrt{|\mu n|}}{c}\right)}{c} & \textit{otherwise.}\end{cases} \tag{2.8}$$

The following proposition shows that the vanishing of Kloosterman sums automatically forces certain even level Rademacher sums to be in the plus space.

Proposition 2.8. *The Rademacher sum* $R^{[\mu]}_{\frac{3}{2},4N}$ *is automatically in the plus space if* N *is even and* $\mu \equiv 0,3 \pmod 4$. *Moreover, if* $N,\mu\equiv 0 \pmod 4$, *then the Fourier coefficients of* $R^{[\mu]}_{\frac{3}{2},4N}$ *are supported on exponents divisible by* 4.

Proof. We begin by noting that if c is divisible by 8, then the Kloosterman sum $K(m,n,c)$ in (2.2) vanishes unless $m-n\equiv 0,3 \pmod 4$. If c is divisible by 16, the same sum vanishes unless $m\equiv n \pmod 4$. Therefore, the claim follows from Theorem 2.5. ☐

Remark. This is an easy restatement (and slight correction) of [54, Lemma 2.10].

Remark. Proposition 2.8 actually follows from the splitting properties of the Weil representation, which is a stronger statement than the vanishing of Kloosterman sums we employed in the proof. However, since we don't use the language of vector-valued modular forms in this paper we use the above more elementary argument.

Remark. We note that the formulas in Proposition 2.7 also hold for even N if one defines the projection operator pr for even levels as a suitable sieving operator, which one easily sees by a comparison to Theorem 2.5.

3. THE RELEVANT MODULAR FORMS

Here we use the results from the previous section to realize the McKay–Thompson series for the O'N-module W whose existence shall be proved later. The main result here is the following theorem. To state it we define a character $\rho_{[g]}:\Gamma_0(4o(g))\to\mathbb{C}^*$ for each conjugacy class $[g]$ of O'N by setting $\rho_{[g]}\left(\begin{smallmatrix} * & * \\ c & * \end{smallmatrix}\right) := (-1)^{\frac{c}{128}}$ when $o(g)=16$, and letting $\rho_{[g]}$ be trivial otherwise.

Theorem 3.1. *Assuming the notation above, the following are true.*

(1) *For every conjugacy class* $[g]$ *of O'N there is a unique weakly holomorphic modular form*

$$F_{[g]}(\tau) = -q^{-4} + 2 + \sum_{n=1} a_{[g]}(n)q^n \tag{3.1}$$

of weight $3/2$ *for the group* $\Gamma_0(4o(g))$*, with character* $\rho_{[g]}$*, satisfying the following conditions:*

  (a) $F_{[g]}(\tau)$ *lies in the Kohnen plus space, i.e.,* $a_{[g]}(n) = 0$ *if* $n \equiv 1, 2 \pmod 4$.

  (b) $F_{[g]}(\tau)$ *has a pole of order* 4 *at the cusp* ∞*, a pole of order* $\frac{1}{4}$ *at the cusp* $\frac{1}{o(g)}$ *if* $o(g)$ *is odd (as forced by the projection to the plus space, see Lemma 2.6), and vanishes at all other cusps.*

  (c) *We have* $a_{[g]}(3) = \chi_7(g)$*, and* $a_{[g]}(4) = \chi_1(g) + \chi_{12}(g) + \chi_{18}(g)$*, and* $a_{[g]}(7)$ *as given in Tables B.1 to B.3, where* χ_j*, for* $j = 1, ..., 30$*, denotes the* j^{th} *irreducible character of O'N as given in Table A.1.*

(2) *The function* $F_{[g]}(\tau)$ *above has integer Fourier coefficients.*

Remark. One can also give a more intrinsic description of the conditions in part (c) above. The proof of the theorem will show that $F_{[g]}$ is already determined by conditions (a) and (b) in part (1), for the 19 conjugacy classes $[g]$ such that $o(g) \notin \{11, 14, 15, 16, 19, 28, 31\}$. For the remaining conjugacy classes we remark that whenever a prime p divides $o(g)$, we need the congruence

$$a_{[g]}(n) \equiv a_{[g']}(n) \pmod p \tag{3.2}$$

where $o(g') = o(g)/p$ in order for these to be generalized characters for *O'N*. Whenever one can choose the coefficient $a_{[g]}(n)$ for the function $F_{[g]}$—which turns out to be the case for $n = 3$ and $o(g) \in \{11, 15, 16\}$, for $n = 4$ for $o(g) \in \{14, 19\}$ and for $n \in \{4, 7\}$ for $o(g) \in \{28, 31\}$—we pick the least integer in absolute value satisfying (3.2) for all primes $p|o(g)$.

Remark. The mod 2 cohomology of the O'Nan group was computed by Adem–Milgram [2]. Using this, Johnson-Freyd–Treumann determined [65] that $H^4(O'N, \mathbb{Z})$ is cyclic of order 8. Furthermore, they have explained to us [64] that there is an element whose image under the restriction map $H^4(O'N, \mathbb{Z}) \to H^4(\langle g\rangle, \mathbb{Z})$ is zero unless $o(g) = 16$, in which case it is the element of order 2 in $H^4(\mathbb{Z}/16\mathbb{Z}, \mathbb{Z}) \simeq \mathbb{Z}/16\mathbb{Z}$. The significance of this is that if V is a holomorphic vertex operator algebra with an action by a finite group G then it is conjectured that the (G-twisted) representation theory of V, including the modularity of its associated trace functions, is controlled by an element of $H^4(G, \mathbb{Z}) \simeq H^3(G, U(1))$. In particular, an element of $H^4(G, \mathbb{Z})$ associates a multiplier system on $\Gamma_0(o(g))$ to each $g \in G$. The above statements about $H^4(O'N, \mathbb{Z})$ imply that there is an element that associates the trivial multiplier to $\Gamma_0(o(g))$ for all $g \in O'N$ except those with $o(g) = 16$, and in the latter case the multiplier arising is the order two character on $\Gamma_0(16)$ with kernel $\Gamma_0(32)$. That is, the characters determined by this element of $H^4(O'N, \mathbb{Z})$ are exactly those that are satisfied by the Jacobi forms $\varphi_{[g]}$ of Equation (1.1), and this is compatible with the existence of a holomorphic vertex operator algebra that realizes these functions, and hence also the $F_{[g]}$, and the *O'N*-module of Theorem 1.1. We refer to §2 of [49], and references therein, for more on the relationship between $H^3(G, U(1))$, modular forms and vertex operator algebra. We refer to §3.2 of [42] for a recent account of the aforementioned conjecture on vertex operator algebras.

Remark. The O'Nan group has a non-split extension $4^3 \cdot \mathrm{GL}_3(2)$ as a subgroup, whilst the sporadic simple Higman–Sims group contains a splitting extension $4^3 : \mathrm{GL}_3(2)$. In both cases the mentioned subgroups contain Sylow 2-subgroups, so can be used to detect the existence, or not, of 2-power elements in the cohomology of the corresponding simple groups. There may be something to be gained from a comparison of these groups, especially in light of the fact that the Higman–Sims group inherits a natural counterpart to monstrous moonshine by virtue of generalized moonshine, and the fact that it appears in the centralizers of suitable elements of order 5 in the monster. We thank an anonymous referee for offering this observation. We also thank the referee for pointing out that the extensions of $\mathrm{GL}_3(2)$ by 4^3 were studied by Alperin [5] and Griess [53]. Results on the cohomology of the Higman–Sims group can be found in [1] and [65].

Proof of Theorem 3.1. Let $g \in O'N$ be any element with $o(g) \neq 16$. Then the difference of Rademacher sums

$$-R^{[-4]}_{\frac{3}{2},4o(g)}(\tau) + 2R^{[0]}_{\frac{3}{2},4o(g)}(\tau)$$

of level $4o(g)$ is a mock modular form with the correct principal part at infinity and vanishes at all other cusps by Theorem 2.5. If $o(g)$ is even, then we know from Proposition 2.8 that this function is in the plus space. If on the other hand, $o(g)$ is odd, then we use the projection operator $|\,\mathrm{pr}$ to map it into the plus space, which by Lemma 2.6 introduces an additional pole of order $\frac{1}{4}$ at the cusp $\frac{1}{o(g)}$. This establishes the existence of a function

$$\widetilde{F}_{[g]}(\tau) := -R^{[-4],+}_{\frac{3}{2},4o(g)}(\tau) + 2R^{[0],+}_{\frac{3}{2},4o(g)}(\tau)$$

satisfying properties (a) and (b) in Theorem 3.1 (1) for $o(g) \neq 16$. To achieve this much for $o(g) = 16$ we use

$$\widetilde{F}_{[g]}(\tau) := -(2R^{[-4],+}_{\frac{3}{2},128}(\tau) - R^{[-4],+}_{\frac{3}{2},64}(\tau)) + 2(2R^{[0],+}_{\frac{3}{2},128}(\tau) - R^{[0],+}_{\frac{3}{2},64}(\tau))$$

since $\rho_{[g]}$ in this case is trivial on $\Gamma_0(128)$, and -1 on $\Gamma_0(64) \setminus \Gamma_0(128)$.

By Lemma 2.4 we see that the above properties determine a mock modular form uniquely up to cusp forms. Unless $o(g) \in \{11, 14, 15, 16, 19, 28, 31\}$ there are no cusp forms of weight $3/2$ in the plus spaces with the required characters, so one checks directly that in all those cases condition (c) is satisfied. In the remaining cases, condition (c) uniquely determines the contribution from cusp forms, because, as one can check using standard computer algebra systems (the authors used MAGMA [13] and PARI [77]), any weight $3/2$ cusp form of one of the given levels in the plus space with the relevant character is uniquely determined by the coefficients of q^3, q^4, and q^7.

We now show that the functions $F_{[g]}$ are actually all weakly holomorphic instead of just mock modular. First suppose that $o(g)$ is odd or $2||o(g)$. Then, because in those cases $o(g)$ is square-free, the shadow of $F_{[g]}(\tau)$ must be a multiple of

$$\vartheta(\tau) := \sum_{n\in\mathbb{Z}} q^{n^2},$$

which follows from the Serre-Stark basis theorem [83]. We compute Bruinier–Funke pairings (see Proposition 3.5 in [18]) and find that

$$\{\widehat{R^{[-4],+}_{\frac{3}{2},4o(g)}}(\tau),\vartheta(\tau)\}=2c \qquad \text{and} \qquad \{\widehat{R^{[0],+}_{\frac{3}{2},4o(g)}}(\tau),\vartheta(\tau)\}=c,$$

where c is some constant. This shows that the shadow of the mock modular form $F_{[g]}(\tau)=-R^{[-4],+}_{\frac{3}{2},4o(g)}(\tau)+2R^{[0],+}_{\frac{3}{2},4o(g)}(\tau)$ is 0, whence it is indeed a weakly holomorphic modular form.

If $o(g)$ is divisible by 4 or 8, but not 16, the space of possible shadows is *a priori* 2-dimensional, generated by $\vartheta(\tau)$ and $\vartheta(4\tau)$, but Proposition 2.8 and the fact that the shadow of a Rademacher sum is again a Rademacher sum show that the shadow's Fourier coefficients must be supported on exponents divisible by 4. So in fact, only multiples of $\vartheta(4\tau)$ can occur as shadows and the same computation as above shows the claim in these cases. For $o(g)=16$ the space of possible shadows is a priori one-dimensional, spanned by $\vartheta(\tau)-\vartheta(4\tau)$, but this function is supported on odd exponents so is also ruled out by the Rademacher sum construction.

It remains to show that the coefficients of the $F_{[g]}$ are all rational integers. This follows by checking finitely many coefficients and applying Sturm's Theorem [87], in a manner directly similar to the proof of Proposition 3.2 in [54], for example. As we will also see in Section 4.1, a possible bound up to which coefficients need to be checked to verify the claim is 225. ☐

4. Proof of Theorem 1.1

Here we prove that the weakly holomorphic modular forms given in Theorem 3.1 are McKay–Thompson series for the infinite-dimensional $O'N$-module W. We begin by stating a refined form of Theorem 1.1.

Theorem 4.1. *There is an infinite-dimensional graded virtual O'N-module*

$$W=\bigoplus_{\substack{m=3\\ m\equiv 0,3 \pmod 4}}^{\infty} W_m$$

such that we have

$$\mathrm{tr}(g|W_m)=a_{[g]}(m),$$

for all m. Moreover, W_m is an honest O'N-module for $m\notin\{7,8,12,16\}$ (see Tables B.1 to B.3).

We break down the proof of this theorem into separate pieces. Using the Schur orthogonality relations on the irreducible representations of $O'N$ we construct weakly holomorphic modular forms of weight $3/2$ whose coefficients are the multiplicities of the irreducible components if and only if W exists. Then the proof of Theorem 4.1 boils down to proving that these multiplicities are integral for all m, and non-negative for $m\notin\{7,8,12,16\}$. In Section 4.1 we establish integrality, and in Section 4.2 we establish the claim on non-negativity.

4.1. **Integrality of Multiplicities.** For every prime $p|\#O'N$ we find linear congruences among the alleged McKay–Thompson series. Here, we prove these, but first we note that their truth implies the following systematic congruences.

Theorem 4.2. *Let $g_j \in O'N$ of order d_j, $j = 1, 2$, with $d_2 = p^c \cdot d_1$ for some prime number p and $c \geq 1$. Then we have the congruence*

$$F_{[g_1]} \equiv F_{[g_2]} \pmod{p}.$$

In Appendix C, we list these congruences, which sometimes hold with higher prime power moduli than stated in Theorem 4.2. Assuming their correctness for the moment, we can show integrality just as described in [54]. For the convenience of the reader, we recall the method briefly.

Let $\mathbf{C} \in \mathbb{Z}^{30\times\infty}$ denote the matrix formed by the coefficients of the functions $F_{[g]}(\tau)$ for each of the 30 conjugacy classes of $O'N$ (in practice one uses a $30 \times B$ matrix for some large B). Further denote by $\mathbf{X} \in \overline{\mathbb{Q}}^{30\times 30}$ the matrix whose rows are indexed by irreducible characters and whose columns are indexed by conjugacy classes of $O'N$, with

$$\mathbf{X}_{\chi,[g]} := \frac{\overline{\chi(g)}}{\#C(g)},$$

where $C(g)$ denotes the centralizer of $g \in O'N$. By the first Schur orthogonality relation we see that the matrix

$$\mathbf{m} := \mathbf{XC}$$

gives the multiplicities of each irreducible representation in the alleged virtual representation in Theorem 4.1. Since there are repetitions among the rows of $\mathbf{C}$, because the functions $F_{[g]}(\tau)$ depend only on the order of elements in $[g]$, it does not have full rank, but by just deleting the repetitions it does turn out to have full rank, which is 18. Let $\mathbf{N}^* \in \mathbb{Z}^{18\times 30}$ denote the matrix performing this operation and let $\mathbf{N} \in \mathbb{Z}^{30\times 18}$ be the matrix that undoes it, so that

$$\mathbf{m} = \mathbf{XNN}^*\mathbf{C}.$$

Now for each prime $p|\#O'N$, we can reduce the matrix $\mathbf{N}^*\mathbf{C}$ according to the aforementioned congruences as in [54] by left-multiplying by a matrix $\mathbf{M}_p \in \mathbb{Q}^{18\times 18}$, which may be seen to have full rank. Hence we get

$$\mathbf{m} = (\mathbf{XNM}_p^{-1}) \cdot (\mathbf{M}_p\mathbf{N}^*\mathbf{C}).$$

The congruences in Appendix C ensure that the matrix $\mathbf{M}_p\mathbf{N}^*\mathbf{C} \in \mathbb{Q}^{18\times\infty}$ has all integer entries and one can check directly that the matrix $\mathbf{XNM}_p^{-1} \in \overline{\mathbb{Q}}^{30\times 18}$ has p-integral (rational) entries for every p. This shows that $\mathbf{m}$ has p-integral entries as well for each $p|\#O'N$, hence its entries must be integers, as claimed.

It remains to show the congruences. Since by Theorem 3.1 all the functions $F_{[g]}$ are weakly holomorphic modular forms, we can prove all the congruences with standard techniques from the theory of modular forms. For example, we may multiply each of the congruences by the unique cusp form g in $S^+_{\frac{25}{2}}(\Gamma_0(4))$ such that $g(\tau) = q^4 + O(q^5)$ (which has integral coefficients), thereby reducing the problem to congruences among holomorphic modular forms of weight

14. These can be checked in all cases using the Sturm bound [87], which is at most 225 in all cases.

4.2. **Positivity of Multiplicities.** Denote by $\mathrm{mult}_j(n)$ the multiplicity of the irreducible character χ_j of $O'N$ in the virtual module W_n as in Theorem 4.1, whose associated generalized character is given by the coefficients $a_{[g]}(n)$, cf. Theorem 3.1. Then the Schur orthogonality relations and the triangle inequality tell us that

$$\begin{aligned}\mathrm{mult}_j(n) &= \sum_{[g]\subseteq O'N} \frac{1}{\#C(g)} a_{[g]}(n)\overline{\chi_j(g)} \\ &\geq \frac{|a_1(n)|}{\#O'N}\chi_j(1) - \sum_{[g]\neq 1A} \frac{|a_{[g]}(n)|}{\#C(g)}|\chi_j(g)|,\end{aligned} \tag{4.1}$$

where the summations run over conjugacy classes of $O'N$. Hence in order to show the eventual positivity of all $\mathrm{mult}_j(n)$, we want to establish explicit lower bounds on $a_{1A}(n)$, and upper bounds on $a_{[g]}(n)$ for $g \neq 1$. Recall that

$$F_{[g]}(\tau) = -q^{-4} + 2 + \sum_{n=1}^{\infty} a_{[g]}(n)q^n = -R^{[-4],+}_{\frac{3}{2},4o(g)}(\tau) + 2R^{[0],+}_{\frac{3}{2},4o(g)}(\tau) + \text{cusp form}$$

for $o(g) \neq 16$, and

$$F_{[g]}(\tau) = -(2R^{[-4],+}_{\frac{3}{2},128}(\tau) - R^{[-4],+}_{\frac{3}{2},64}(\tau)) + 2(2R^{[0],+}_{\frac{3}{2},128}(\tau) - R^{[0],+}_{\frac{3}{2},64}(\tau))$$

for $o(g) = 16$. (For $o(g) = 16$ we have $\dim S^{+}_{\frac{3}{2}}(\Gamma_0(4o(g)), \rho_{[g]}) = 1$ but condition (c) in Theorem 3.1 rules out any cuspidal contribution to $F_{[g]}$. Cf. Appendix D.)

We bound each of the components individually, following the strategy already employed in [37, 49, 54], which we sketch briefly for the convenience of the reader. Note however that in the cited papers, only the coefficients of one Rademacher sum had to be considered, since the corrections there were known to come from weight $\frac{1}{2}$ modular forms, whose coefficients are bounded. In our case the corrections can grow with n.

Since the computations necessary to bound the contribution coming from the Rademacher sum $R^{[-4]}_{\frac{3}{2},4N}$, which is obviously going to be the dominant part, have been carried out in detail in [49, 54], we omit them here. The idea is to use the known formula for the coefficients of the Rademacher sum in terms of infinite sums of Kloosterman sums weighted by I-Bessel functions, see Section 2. One then splits this sum into three parts, a dominant part, an absolutely convergent remainder term and a value of a *Selberg–Kloosterman zeta function*, the first two of which may be bounded by elementary means, and for the third, one uses Proposition 4.1 in [54] (which we note is directly applicable to our situation).

4.2.1. *Bounding Coefficients of Rademacher Sums.* From Proposition 5.2 below, we see that the $\mu = 0$ Rademacher sum can be explicitly given in terms of generating functions of generalized Hurwitz class numbers $H^{(N)}(n)$ (see Section 5 for the definition). While strong bounds for class numbers are known (see for instance Chapter 23 in [63] and the references therein), they are usually not explicit. For our purposes, crude bounds on class numbers suffice.

Proposition 4.3. *For every $N \in \mathbb{N}$, $-D \leq -5$ a negative discriminant and $\varepsilon > 0$ we have*

$$H^{(N)}(D) \leq [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)] c_\varepsilon D^\varepsilon \cdot \frac{\sqrt{D}}{2\pi}\left(1 + \frac{1}{2}\log D\right),$$

where we can choose

$$c_\varepsilon = \prod_{p < e^{\frac{1}{2\varepsilon}}} (2\varepsilon p^{1/\log p - 2\varepsilon} \log p)^{-1}.$$

Proof. First we note that we trivially have the bound $H^{(N)}(D) \leq [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)] H^{(1)}(D)$ by definition. Now suppose for the moment that D is a fundamental discriminant. Then Dirichlet's class number formula gives

$$H(D) = \frac{\sqrt{D}}{2\pi} \cdot L\left(1, \left(\frac{-D}{\bullet}\right)\right).$$

Theorem 13.3 of Chapter 12 in [61] tells us that for $D \geq 5$ we have the upper bound

$$L\left(1, \left(\frac{-D}{\bullet}\right)\right) < 1 + \frac{1}{2}\log D.$$

By [97, pp. 73f.], Dirichlet's formula is also valid for non-fundamental discriminants if only primitive forms are counted, so that we get the bound

$$H(D) \leq \tau_\square(D) \frac{\sqrt{D}}{2\pi}\left(1 + \frac{1}{2}\log D\right),$$

where $\tau_\square(n)$ denotes the number of square divisors of n. Considering the prime factorisation of D, it is elementary to see that $\tau_\square(D) \leq c_\varepsilon D^\varepsilon$ for any $\varepsilon > 0$ and c_ε as claimed. ☐

This result together with Proposition 5.2 gives a sufficient and explicit bound for the coefficients of the Rademacher sum $R^{[0],+}_{\frac{3}{2},4N}$. For the actual computations we choose $\varepsilon = \frac{1}{8}$, which yields $c_\varepsilon \approx 10.6766$.

4.2.2. *Bounding Coefficients of Cusp Forms.* For $g \in O'N$ with

$$o(g) \in \{11, 14, 15, 19, 28, 31\},$$

there are non-trivial cusp forms in $S^+_{\frac{3}{2}}(\Gamma_0(4o(g)))$ contributing to our modular forms $F_{[g]}$, see Appendix D. According to the Ramanujan–Petersson conjecture, the coefficients of these cusp forms should grow like $O(n^{\frac{1}{4}+\varepsilon})$ (for n square-free). Unconditional bounds (again for square-free n) have been obtained by Iwaniec [62] for weights $\geq 5/2$ and Duke [32] for weight 3/2 (see also [33]). These bounds have one main disadvantage for our purposes, namely that the constants involved in them are not explicit or not computable. Here, we outline how to give completely explicit and computable, but very crude, estimates for the cusp form coefficients in question.

Let $P^{[m]}_{4N}$ denote the cuspidal Poincaré series of weight 3/2 characterized by the *Petersson coefficient formula*,

$$\langle f, P^{[m]}_{4N} \rangle = \frac{b_f(m)}{[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(4N)]\sqrt{4m}} \quad \forall\ f(\tau) = \sum_{n=1}^{\infty} b_f(n) q^n \in S^+_{\frac{3}{2}}(\Gamma_0(4N)), \tag{4.2}$$

where the Petersson inner product on $S^+_{\frac{3}{2}}(\Gamma_0(4N))$ is defined by the usual double integral

$$\langle f_1, f_2\rangle = \frac{1}{[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(4N)]}\int_{\Gamma_0(4N)\backslash\mathfrak{H}} f_1(\tau)\overline{f_2(\tau)}y^{\frac{3}{2}}\frac{du\,dv}{v^2}.$$

The Fourier coefficients of these Poincaré series are given in terms of infinite sums of Kloosterman sums times J-Bessel functions (see Proposition 4 in [66]), and essentially the same computation used to bound the coefficients of the Rademacher sums $R^{[-4]}_{\frac{3}{2},4N}$ can be used here as well. It is then only necessary to express the cusp forms $\mathscr{G}^{(o(g))}$ (see again Appendix D) in terms of these Poincaré series, which is particularly easy in the cases where $o(g) \neq 31$ is odd, since in those cases, the space $S^+_{\frac{3}{2}}(\Gamma_0(4o(g)))$ is one-dimensional and $\mathscr{G}^{(o(g))}$ is a newform. Hence we have $\langle \mathscr{G}^{(o(g))}, P^{[m]}_{4N}\rangle = \beta\langle \mathscr{G}^{(o(g))}, \mathscr{G}^{(o(g))}\rangle$, where we choose m to be the order of $\mathscr{G}^{(o(g))}$ at ∞. It therefore remains to compute the Petersson norm of the newform $\mathscr{G}^{(o(g))}$. This can be done by means of the following result due to Kohnen, which is an explicit version of Waldspurger's theorem (see Corollary 1 in [66]).

Proposition 4.4. *Let $N \in \mathbb{N}$ be odd and square-free, $f \in S^+_{k+\frac{1}{2}}(\Gamma_0(4N))$ be a newform and $F \in S_{2k}(\Gamma_0(N))$ the image of f under the Shimura correspondence. For a prime $\ell | N$, let w_ℓ be the eigenvalue of F under the Atkin–Lehner involution W_ℓ and choose a fundamental discriminant D with $(-1)^k D > 0$ and $\left(\frac{D}{\ell}\right) = w_\ell$ for all ℓ. Then we have*

$$\langle f, f\rangle = \frac{\langle F, F\rangle \pi^k}{2^{\omega(N)}(k-1)!|D|^{k-\frac{1}{2}}L(F, D; k)} \cdot |b_f(|D|)|^2,$$

where $L(F, D; s)$ denotes the twist of the newform F by the quadratic character $\left(\frac{D}{\bullet}\right)$ and $\omega(N)$ denotes the number of distinct prime divisors of N.

Since the twisted L-series has a functional equation of the usual type, there are efficient methods to compute its values numerically. (The authors used the built-in intrinsics of Magma [13].) Computing the Petersson norm of F is also possible to high accuracy, e.g. by using the well-known relationship (cf. [30, 98])

$$\langle F, F\rangle = \frac{\mathrm{vol}(E)}{4\pi^2}\deg(\varphi_E),$$

where F is the newform associated to the elliptic curve $E/\mathbb{Q}$, we denote the covolume of the period lattice of E by $\mathrm{vol}(E)$, and use φ_E for the modular parametrization of E. (Every elliptic curve E we consider in this paper has $\deg(\varphi_E) = 1$.) Alternatively, the Petersson norm of F is computed for N prime by Theorem 2 in [98].

Remark. Kohnen's result Proposition 4.4 has been extended to many situations, e.g. by Ueda and his collaborators [91, 92] to certain even levels and forms not in the plus-space (see in particular Corollary 1 in [69]). So the above reasoning carries over to $o(g) \in \{14, 28\}$, by noting that $\mathscr{G}^{(14)}$ and $\mathscr{G}^{(28)}$ both arise from the unique normalized cusp form in $S_{\frac{3}{2}}(\Gamma_0(28))$ (not in the plus space). The former may be obtained by applying sieve operators, the latter by applying the V_4-operator.

Remark. For $o(g) = 31$, the above reasoning only needs to be modified to take into account that $\mathscr{G}^{(31)}$ is not a Hecke eigenform, but its decomposition into newforms is given in Appendix D. Using the fact that these newforms are orthogonal, the only difference becomes that one needs to take into account two Poincaré series instead of one.

Putting the estimates for the Rademacher sums $R^{[-4]}_{\frac{3}{2},4N}$, $R^{[0]}_{\frac{3}{2},4N}$, and the occuring cusp forms together and plugging them all into (4.1), one finds that the multiplicities are nonnegative as soon as $n \geq 113$ (the worst case occurs for the character χ_1). Inspecting the remaining coefficients by computer then completes the proof of Theorem 4.1.

5. TRACES OF SINGULAR MODULI

In this section, we discuss and recall some basic notation and facts about traces of singular moduli. Their study originates in seminal work by Zagier [99], and has since been an important subject in number theory (cf. for instance [8, 16, 19, 70], just to name a few). They appeared in connection with moonshine for the Thompson group in [58].

5.1. **Genus Zero Levels.** It is well-known that for $N \in \{1,2,3,4,5,6,7,8,10,12,16\}$ the modular curve $X_0(N)$ has genus 0, so that in those cases, there is a Hauptmodul $J^{(N)}$. These Hauptmoduln are given explicitly in Table 5.1 in terms of the Dedekind eta function $\eta(\tau) := q^{\frac{1}{24}}\prod_{n>0}(1-q^n)$ and the Eisenstein series $E_4(\tau) := 1 + 240\sum_{n>0} n^3q^n(1-q^n)^{-1}$.

N	$J^{(N)}(\tau)$
1	$\frac{E_4(\tau)^3}{\eta(\tau)^{24}} - 744$
2	$\frac{\eta(\tau)^{24}}{\eta(2\tau)^{24}} + 24$
3	$\frac{\eta(\tau)^{12}}{\eta(3\tau)^{12}} + 12$
4	$\frac{\eta(\tau)^{8}}{\eta(4\tau)^{8}} + 8$
5	$\frac{\eta(\tau)^{6}}{\eta(5\tau)^{6}} + 6$
6	$\frac{\eta(\tau)^{5}\eta(3\tau)}{\eta(2\tau)\eta(6\tau)^{5}} + 5$
7	$\frac{\eta(\tau)^{4}}{\eta(7\tau)^{4}} + 4$
8	$\frac{\eta(\tau)^{4}\eta(4\tau)^2}{\eta(2\tau)^2\eta(8\tau)^{4}} + 4$
10	$\frac{\eta(\tau)^{3}\eta(5\tau)}{\eta(2\tau)\eta(10\tau)^{3}} + 3$
12	$\frac{\eta(\tau)^{3}\eta(4\tau)\eta(6\tau)^2}{\eta(2\tau)^2\eta(3\tau)\eta(12\tau)^{3}} + 3$
16	$\frac{\eta(\tau)^{2}\eta(8\tau)}{\eta(2\tau)\eta(16\tau)^{2}} + 2$

TABLE 5.1. Hauptmoduln for some $\Gamma_0(N)$

To make use of these Hauptmoduln we require some notation. Denote by $\mathcal{Q}^{(N)}_{-D}$ the set of positive definite quadratic forms $Q = ax^2 + bxy + cy^2 =: [a,b,c]$ of discriminant $-D = b^2 - 4ac < 0$ such that $N|a$. It is well-known that $\Gamma_0(N)$ acts on $\mathcal{Q}^{(N)}_{-D}$ with finitely many orbits, which correspond to the so-called *Heegner points* on the modular curve $X_0(N)$. For $Q = [a,b,c] \in \mathcal{Q}^{(N)}_{-D}$, we denote by $\tau_Q := \frac{-b+i\sqrt{D}}{2a}$ the unique root of $Q(x,1)$ in $\mathfrak{H}$. For a function $f : \mathfrak{H} \to \mathbb{C}$ invariant under the action of $\Gamma_0(N)$ we then define the trace function

$$\mathrm{Tr}^{(N)}_D(f) := \sum_{Q \in \mathcal{Q}^{(N)}_{-D}/\Gamma_0(N)} \frac{f(\tau_Q)}{\omega^{(N)}(Q)}, \tag{5.1}$$

where $\omega^{(N)}(Q) = \frac{1}{2} \cdot \# \operatorname{Stab}_{\Gamma_0(N)}(Q)$. Further let

$$\mathscr{H}^{(N)}(\tau) := -\frac{[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)]}{12} + \sum_{\substack{D>0 \\ D\equiv 0,3 \pmod 4}} H^{(N)}(D) q^D$$

denote the generating function of the *(generalized) Hurwitz class numbers of level N* which are defined as $H^{(N)}(D) := \operatorname{Tr}_D^{(N)}(1)$. The special case of $N = 1$ yields the classical Hurwitz class numbers $H^{(1)}(D) := H(D)$.

It is a straightforward consequence of Theorem 1.2 in [70], analogous to Theorem 1.2 in [8], that we can describe the Fourier coefficients of the Rademacher sums $R^{[-4],+}_{\frac{3}{2},4N}$ as traces of the Hauptmoduln in Table 5.1.

Proposition 5.1. *Let $N \in \mathbb{N}$ such that $X_0(N)$ has genus 0 and*

$$\operatorname{Tr}_4^{(N)}(D) := \frac{1}{2}\left(\operatorname{Tr}_D^{(N)}(J_2^{(N)}) - \operatorname{Tr}_D^{(N/d)}(J^{(N/d)})\right), \tag{5.2}$$

where $J_2^{(N)} = q^{-2} + O(q)$ is the unique modular function for $\Gamma_0(N)$ with this Fourier expansion at infinity and no poles anywhere else and $d := \gcd(N, 2)$. Then we have

$$\mathscr{T}^{(N)}(\tau) := -q^{-4} + \sum_{\substack{D>0 \\ D\equiv 0,3 \pmod 4}} \operatorname{Tr}_4^{(N)}(D) q^D = -R^{[-4],+}_{\frac{3}{2},4N}(\tau) - \frac{c_2}{2}\mathscr{H}^{(N)}(\tau) + \frac{c_1}{2}\mathscr{H}^{(N/d)}(\tau) \tag{5.3}$$

for certain rational numbers c_1 and c_2. In particular, the function $\mathscr{T}^{(N)}$ has integer Fourier coefficients.

Remark. It should be pointed out that Theorem 1.2 in [70] is only stated for odd levels, although the proof goes through for even levels as well.

Remark. The rational numbers c_2 and c_1 in Proposition 5.1 are the constant terms of the weight 0 Rademacher sums $R^{[-2]}_{0,N}$ and $R^{[-1]}_{0,N/d}$, respecitvely. For a proof of the rationality of these numbers see Lemma 3.2 in [8].

For the Rademacher sum $R^{[0],+}_{\frac{3}{2},4N}$ we get the following.

Proposition 5.2. *For $N \in \mathbb{N}$ we have*

$$R^{[0],+}_{\frac{3}{2},4N} = -\frac{12}{\varphi(N)} \sum_{d|N} \frac{d}{[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(d)]} \mu\left(\frac{N}{d}\right) \mathscr{H}^{(d)}$$

where μ and φ denote the Möbius function and Euler's totient function, respectively.

Proof. This follows from a straightforward modification of the proof of Theorem 1.2 in [70]. □

Note that the above Proposition 5.2 is indeed valid for all N, not just those such that $X_0(N)$ has genus 0.

Putting Propositions 5.1 and 5.2 together we obtain explicit descriptions of the functions $F_{[g]}$ in terms of singular moduli for $o(g) \in \{1, 2, 3, 4, 5, 6, 7, 8, 10, 12\}$. These are given in Appendix D.

5.2. **Positive Genus Levels.** In the remaining cases, i.e. where

$$o(g) \in \{11, 14, 15, 16, 19, 20, 28, 31\},$$

our $F_{[g]}$ involve (cf. the proof of Theorem 3.1) Rademacher sums $R^{[-4],+}_{\frac{3}{2},4N}$ where N is such that $X_0(N)$ has positive genus. So there is no notion of a Hauptmodul there. However, it is known that for all these levels, the modular curve $X_0^+(N)$, being the quotient of $X_0(N)$ by all Atkin–Lehner involutions, does have genus 0 (see e.g. [43]). So there exists a Hauptmodul $J^{(N,+)}(\tau)$ for the corresponding group $\Gamma_0^+(N)$. See Table 5.2 for these. There, $E_2(\tau) := 1 - 24\sum_{n>0} nq^n(1-q^n)^{-1}$ is the quasimodular Eisenstein series, $f_{19} = q - 2q^3 + O(q^4)$ denotes the weight 2 newform associated to the elliptic curve

$$E_{19} : y^2 + y = x^3 + x^2 - 9x - 15$$

([68, Elliptic Curve 19.a2]), and $f_{31} = q + \frac{1+\sqrt{5}}{2}q^2 + O(q^3)$ denotes the unique newform in $S_2(\Gamma_0(31))$ up to Galois conjugation (which is denoted by an exponent σ).

N	11	14
$J^{(N,+)}(\tau)$	$-\frac{E_2(\tau)-11E_2(11\tau)}{10\eta(\tau)^2\eta(11\tau)^2} - \frac{22}{5}$	$-\frac{E_2(\tau)+2E_2(2\tau)-7E_2(7\tau)-14E_2(14\tau)}{18\eta(\tau)\eta(2\tau)\eta(7\tau)\eta(14\tau)} - \frac{7}{3}$

N	15	16
$J^{(N,+)}(\tau)$	$-\frac{E_2(\tau)+3E_2(3\tau)-5E_2(5\tau)-15E_2(15\tau)}{16\eta(\tau)\eta(3\tau)\eta(5\tau)\eta(15\tau)} - \frac{5}{2}$	$\frac{\eta(2\tau)^6\eta(8\tau)^6}{\eta(\tau)^4\eta(4\tau)^4\eta(16\tau)^4} - 4$

N	19	20	28
$J^{(N,+)}(\tau)$	$-\frac{E_2(\tau)-19E_2(19\tau)}{18f_{19}(\tau)} - \frac{4}{3}$	$\frac{\eta(2\tau)^8\eta(10\tau)^8}{\eta(\tau)^4\eta(4\tau)^4\eta(5\tau)^4\eta(20\tau)^4} - 4$	$\frac{\eta(2\tau)^6\eta(14\tau)^6}{\eta(\tau)^3\eta(4\tau)^3\eta(7\tau)^3\eta(28\tau)^3} - 3$

N	31	32
$J^{(N,+)}(\tau)$	$\frac{\sqrt{5}(f_{31}(\tau)+f_{31}^{\sigma}(\tau))}{2(f_{31}(\tau)-f_{31}^{\sigma}(\tau))} - \frac{5}{2}$	$\frac{\eta(2\tau)^3\eta(16\tau)^3}{\eta(\tau)^2\eta(4\tau)\eta(8\tau)\eta(32\tau)^2} - 2$

TABLE 5.2. Hauptmoduln for some $\Gamma_0^+(N)$

Armed with these Hauptmoduln we can now express the Fourier coefficients of all the remaining Rademacher sums $R^{[-4],+}_{\frac{3}{2},4N}$ in terms of singular moduli of holomorphic modular functions and class numbers.

Proposition 5.3. *Let $N \in \mathbb{N}$ such that $X_0^+(N)$ has genus 0 and define*

$$\mathrm{Tr}_4^{(N,+)}(D) := \frac{1}{2}\left(\frac{1}{2^{\omega(N)}}\,\mathrm{Tr}_D^{(N)}\left(J_2^{(N,+)}\right) - \frac{1}{2^{\omega(N/d)}}\,\mathrm{Tr}_D^{(N/d)}\left(J^{(N/d,+)}\right)\right) \tag{5.4}$$

where $J_2^{(N,+)} = q^{-2} + O(q)$ *is the unique modular function for* $\Gamma_0^+(N)$ *with this Fourier expansion at infinity and no poles anywhere else and* $d := \gcd(N,2)$*. Then we have*

(5.5)

$$\mathscr{T}^{(N,+)}(\tau) := -q^{-4} + \sum_{\substack{D>0\\ D\equiv 0,3 \pmod 4}} \mathrm{Tr}_4^{(N,+)}(D)q^D = -R^{[-4],+}_{\frac{3}{2},4N}(\tau) - \frac{c_2}{2}\mathscr{H}^{(N)}(\tau) + \frac{c_1}{2}\mathscr{H}^{(N/d)}(\tau)$$

for some rational numbers c_1 *and* c_2*, where* $\omega(N)$ *denotes the number of distinct prime factors of* N*.*

Proof. Proposition 5.1 turns out to be valid for all N, if one replaces the Hauptmodul $J^{(N)}$ by the completed Rademacher sum $\widehat{R^{[-1]}_{0,N}}$, normalized so that its constant term is 0 and $J_2^{(N)}$ by $\widehat{R^{[-2]}_{0,N}}$ with the same normalization, which is the original formulation in [70]. Note that these Rademacher sums coincide with the Hauptmoduln where applicable. Now we consider for $N'||N$, i.e. $\gcd(N', N/N') = 1$, the Atkin–Lehner involution $W_{N'}$. These involutions map the set $\mathcal{Q}^{(N)}_{-D}/\Gamma_0(N)$ bijectively to itself (see e.g. Section 1 of [56]), so for any $\Gamma_0(N)$-invariant function f we have that $\mathrm{Tr}_D^{(N)}(f) = \mathrm{Tr}_D^{(N)}(f|W_{N'})$. Since there are exactly $2^{\omega(N)}$ Atkin–Lehner involutions of level N this means that

$$\mathrm{Tr}_D^{(N)}(f) = \frac{1}{2^{\omega(N)}}\mathrm{Tr}_D^{(N)}(\tilde{f})$$

where $\tilde{f} := \sum_{N'||N} f|W_{N'}$. The function $\tilde{f}$ is clearly $\Gamma_0^+(N)$-invariant. By checking the polar parts we conclude that if f is $\widehat{R^{[-1]}_{0,N}}$ or $\widehat{R^{[-2]}_{0,N}}$ then $\tilde{f}$ has to coincide with $J^{(N,+)}$ or $J_2^{(N,+)}$, respectively, up to a rational additive constant. This proves the result. ☐

We now put Propositions 5.2 and 5.3 together to obtain explicit descriptions of the functions $F_{[g]}$ in terms of singular moduli for $o(g) \in \{11, 14, 15, 19, 28, 31\}$. For $o(g) = 16$ we use Proposition 5.1 as well since $F_{[g]}$ involves Rademacher sums $R^{[\mu],+}_{\frac{3}{2},4N}$ for both $N = 16$ and $N = 32$ in this case. The resulting expressions are given in Appendix D.

6. NUMBER THEORETIC APPLICATIONS

In this section we prove the arithmetic applications of O'Nan moonshine given in Theorems 1.2 to 1.4. All these proofs rely on the following easy observation.

Lemma 6.1. *Let* $N > 1$ *be an integers and* $-D < 0$ *a discriminant which is not a square in* $\mathbb{Z}/N\mathbb{Z}$*. Then the set* $\mathcal{Q}^{(N)}_{-D}$ *is empty. In particular, we have that* $\mathrm{Tr}_{-D}^{(N)}(f) = H^{(N)}(D) = 0$ *for any* $\Gamma_0(N)$*-invariant function* f*.*

Proof. A quadratic form $[a,b,c] \in \mathcal{Q}^{(N)}_{-D}$ satisfies $-D = b^2 - 4ac$ and $N|a$, hence if $-D$ is not a square modulo N, there cannot be any such forms. ☐

6.1. **Proof of Theorem 1.2.**

Suppose first that $p \in \{5, 7\}$ and let D be as in Theorem 1.2. The congruences in Appendix C together with the identities in Appendix D imply the congruence

$$\dim(W_D) \equiv \mathrm{tr}(g_p|W_D) \equiv \mathrm{Tr}_4^{(p)}(D) - 24H(D) + \alpha_p H^{(p)}(D) \pmod p$$

for some integer α_p. By Lemma 6.1, the terms $\mathrm{Tr}_4^{(p)}(D)$ and $H^{(p)}(D)$ vanish for D as required, proving the result. For $p = 3$, one replaces the modulus above by 3^2, making the congruence non-trivial.

For $p = 2$, we note that there is a congruence between $\dim W_D$ and $\mathrm{tr}(g_2|W_D)$ modulo 2^{11} by Appendix C. As one easily sees through a Sturm bound argument, we also have

$$\dim W_D \equiv \mathrm{tr}(g_2|W_D) \equiv 0 \pmod{16}$$

for $D \equiv 4, 8 \pmod{16}$, which is the case in particular when $-D < 8$ is an even fundamental discriminant. The fact that for these D the class number is even can be seen in various ways, for example by noting that by a famous theorem of Gauss and Hermite we have that $24H(D) = 2r_3(D/4)$, where $r_3(n)$ is the number of representations of n as the sum of three squares. Since $-D$ is fundamental, it follows that $D/4$ is square-free and hence is not the sum of three or just two equal squares. Through an easy case-by-case analysis one then finds that $r_3(D/4)$ is always divisible by 8. Alternatively, one could also show the modular forms congruence

$$\sum_{n\equiv 1,2 \pmod{4}} r_3(n)q^n \equiv 6\sum_{n=0}^{\infty} q^{(2n+1)^2} + 4\sum_{n=0}^{\infty} q^{2(2n+1)^2} \pmod{8}.$$

This completes the proof.

6.2. **Preliminaries on Elliptic Curves.** The proofs of Theorems 1.3 and 1.4 require a little preparation which we provide in this section.

One of the most important open problems in the theory of elliptic curves is the Birch and Swinnerton-Dyer Conjecture.

Conjecture 6.2. *Let $E/\mathbb{Q}$ be an elliptic curve. Then we have that*

$$\frac{L^{(r)}(E,1)}{r!\Omega_E} = \frac{\#\text{Ш}(E)\cdot \mathrm{Reg}(E)\prod_\ell c_\ell(E)}{(\#E(\mathbb{Q})_{tors})^2}, \tag{6.1}$$

where r denotes the order of vanishing of $L(E,s)$ at $s = 1$, which equals the Mordell–Weil rank of E, Ω_E is the real period of E, $\#\text{Ш}(E)$ and $\mathrm{Reg}(E)$ denote the order of the Tate-Shafarevich group and the regulator of E, respectively, the $c_\ell(E)$ for prime ℓ are the Tamagawa numbers of E, and $\#E(\mathbb{Q})_{tors}$ signifies the order of the torsion subgroup of the $\mathbb{Q}$-rational points of E.

The weak Birch and Swinnerton-Dyer conjecture—that the order of vanishing of $L(E,s)$ at $s = 1$ equals the rank of E—was established for curves of ranks 0 and 1 through work of Gross–Zagier [57] and Kolyvagin [67]. More recently, Bhargava–Shankar [9] proved, using Kolyvagin's theorem and the proof of the Iwasawa main conjectures for GL_2 by Skinner–Urban [86] (among other deep results), that a positive proportion of all elliptic curves satisfy the weak Birch and Swinnerton-Dyer Conjecture.

It is known that the left-hand side of (6.1) is always a rational number, see for instance [3, Theorem 3.2]. The following result shows that in certain situations, a local version of Conjecture 6.2, which is going to be sufficient for our purposes, holds.

Theorem 6.3 ([85], Theorem C)**.** *Let $E/\mathbb{Q}$ be an elliptic curve and $p \geq 3$ a prime of good ordinary or multiplicative reduction. Further assume that the $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$-representation $E[p]$ is irreducible and that there exists a prime $p' \neq p$ at which E has multiplicative reduction and $E[p]$ ramifies. If $L(E,1) \neq 0$, then we have that*

$$\mathrm{ord}_p\left(\frac{L(E,1)}{\Omega_E}\right) = \mathrm{ord}_p\left(\#\text{Ш}(E)\prod_\ell c_\ell(E)\right).$$

If $L(E,1) = 0$, then we have $\mathrm{Sel}(E)[p] \neq \{0\}$.

We are especially interested in quadratic twists of elliptic curves. In this context, the following result by Agashe, giving the real period of such a twist, turns out to be very useful.

Lemma 6.4 ([4], Lemma 2.1)**.** *Let $E/\mathbb{Q}$ be an elliptic curve of conductor N and let $-D < 0$ be a fundamental discriminant coprime to N. Then we have that*

$$\Omega_{E(-D)} = c_E \cdot c_\infty(E(-D)) \cdot \omega_-(E)/\sqrt{D},$$

where c_E denotes the Manin constant of E, $c_\infty(E(-D))$ denotes the number of components of $E(-D)$ over $\mathbb{R}$, and $\omega_-(E)$ denotes the second period of the period lattice of E.

Remark. The famous Manin Conjecture states that $c_E = 1$.

Combining this with a theorem of Kohnen [66] (cf. Proposition 4.4), we obtain the following.

Lemma 6.5. *Let $E/\mathbb{Q}$ be an elliptic curve of odd, square-free conductor N and let $-D < 0$ be a fundamental discriminant satisfying $\left(\frac{-D}{\ell}\right) = w_\ell$, where w_ℓ denotes the eigenvalue of the newform $F_E \in S_2(\Gamma_0(N))$ associated to E and the Atkin–Lehner involution W_ℓ, $\ell|N$. Denote by D_0 the smallest such discriminant. Further let $f_E(\tau) = \sum_{n=3}^\infty b_E(n)q^n \in S^+_{\frac{3}{2}}(\Gamma_0(4N))$ be the weight $3/2$ cusp form associated to F_E under the Shintani lift. For $p \geq 3$ prime we then have that*

$$\mathrm{ord}_p\left(\frac{L(E(-D),1)}{\Omega_{E(-D)}}\right) = \mathrm{ord}_p\left(\frac{L(E(-D_0),1)}{\Omega_{E(-D_0)}}\right) + \mathrm{ord}_p\left(b_E(|D|)^2\right).$$

Proof. By combining Proposition 4.4 and Lemma 6.4, we find for the fundamental discriminants $-D < 0$ as in the lemma that

$$\frac{L(E(-D),1)}{\Omega_{E(-D)}} = \frac{\pi\langle F,F\rangle}{c_E \cdot c_\infty(E(-D))2^{\omega(N)}\langle f,f\rangle\omega_-(E)} \cdot |b_E(D)|^2. \tag{6.2}$$

We see that the only quantities in this formula depending on D are $c_\infty(E(-D))$ and $b_E(D)$. Since the former is always either 1 or 2 and p is odd, it doesn't affect the p-adic valuation at all, which proves the lemma. □

Remark. If the conductor N is even but still square-free, the same result still holds along the same lines, using the remark following Proposition 4.4. The exact formula in this case only differs from (6.2) by a power of 2, which doesn't affect the p-adic valuation.

6.3. **Proofs.** In this section, we prove Theorems 1.3 and 1.4. The proofs of both theorems are very similar in their main steps, so we combine them here.

Proof of Theorems 1.3 and 1.4. By applying the expressions for the relevant $F_{[g]}$ in terms of the traces of singular moduli, class numbers and weight 3/2 cusp forms in Appendix D, and using the congruences in Appendix C, we find that

$$\begin{aligned}
\dim(W_D) \equiv \operatorname{tr}(g_{11}|W_D) &\equiv \mathrm{Tr}_4^{(11)}(D) - 24H(D) + \alpha_{11}H^{(11)}(D) + \gamma_{11}b_{11}(D) \pmod{11},\\
\operatorname{tr}(g_2|W_D) \equiv \operatorname{tr}(g_{14}|W_D) &\equiv \mathrm{Tr}_4^{(14)}(D) + \delta_7(H(D) - \delta_7 H^{(2)}(D))\\
&\qquad + \alpha_7 H^{(7)}(D) + \beta_7 H^{(14)}(D) + \gamma_7 b_{14}(D) \pmod{7},\\
\operatorname{tr}(g_3|W_D) \equiv \operatorname{tr}(g_{15}|W_D) &\equiv \mathrm{Tr}_4^{(15)}(D) + \delta_5(H(D) - \delta_5 H^{(3)}(D))\\
&\qquad + \alpha_5 H^{(5)}(D) + \beta_5 H^{(15)}(D) + \gamma_5 b_{15}(D) \pmod{5},\\
\dim(W_D) \equiv \operatorname{tr}(g_{19}|W_D) &\equiv \mathrm{Tr}_4^{(19)}(D) - 24H(D) + \alpha_{19}H^{(19)}(D) + \gamma_{19}b_{19}(D) \pmod{19},
\end{aligned}$$

where $\delta_p = \frac{p-1}{2}$, α_p, β_p are some integers, γ_p are p-adic units, and $b_N(D)$ denotes the D^{th} coefficient of the weight 3/2 cusp form $\mathscr{G}^{(N)}$ specified in Appendix D. If $-D$ is a fundamental discriminant as specified in Theorems 1.3 and 1.4 respectively, then by Lemma 6.1, the terms $\mathrm{Tr}_4^{(N)}(D)$ as well as $H^{(p)}(D)$ and $H^{(N)}(D)$ above disappear. This shows that the class number congruences in our theorems hold if and only if p divides the coefficient $b_N(D)$, i.e. if and only if $\mathrm{ord}_p\left(\frac{L(E_N(-D),1)}{\Omega_{E_N(-D)}}\right) > 0$ by Lemma 6.5. (A Magma computation reveals that the ratio $\frac{L(E_N(-D_0),1)}{\Omega_{E_N(-D_0)}}$ for the smallest possible D_0 is in each case a p-adic unit.)

Suppose for simplicity that $L(E_N(-D),1) \neq 0$. According to the Birch and Swinnerton-Dyer Conjecture 6.2, this implies that

$$\mathrm{ord}_p(\#\text{Ш}(E_N(-D))\prod_\ell c_\ell(E(-D))) > 0,$$

so our theorems follow, conditionally on Conjecture 6.2, if the Tamagawa numbers $c_\ell(E(-D))$ are never divisible by p in our cases. To establish this, we note (cf. [84, Appendix C, Table 15.1]) that for an elliptic curve $E/\mathbb{Q}$ we have that $p|c_\ell(E)$ if and only if the reduction type of E at ℓ is I_n with $p|n$, which means that $\mathrm{ord}_\ell(\Delta(E)) = n$, where $\Delta(E)$ denotes the (minimal) discriminant of E. An inspection of Tate's algorithm for the computation of Tamagawa numbers and the well-known formulas for minimal discriminants from the Kraus–Laska algorithm reveals that in our case, because we are considering twists of elliptic curves by fundamental discriminants, all the Tamagawa numbers must be in $\{1,2,3,4\}$. The argumentation in the case $L(E(-D),1) = 0$ is similar. This completes the proof of Theorem 1.3 for $N \in \{11, 19\}$.

The truth of Theorem 1.4 does not depend on the Birch and Swinnerton-Dyer Conjecture, but rather on Skinner's Theorem 6.3. A lemma of Serre [82, §2.8, Corollaire, p. 284] shows that the Galois representations $E_{14}(-D)[7]$ and $E_{15}(-D)[5]$ are surjective and hence irreducible. Furthermore, it is immediate to check that $E_{14}(-D)$ (resp. $E_{15}(-D)$) has multiplicative reduction modulo 2 (resp. 3) and that $E_{14}(-D)[7]$ (resp. $E_{15}(-D)[5]$) ramifies there, so the conditions of Theorem 6.3 are satisfied, completing the proof of Theorem 1.4. ☐

7. Examples

Here we offer some numerical examples which illustrate the congruences described in the introduction.

7.1. **Class Number Congruences.** Here we present some class number congruences that arise from Theorem 1.2. Recall that this theorem offers congruences modulo 16, 9, 5, and 7 for certain fundamental discriminants $-D < 0$ which satisfy given congruence conditions. The three columns in Tables 7.1 to 7.4 are congruent, which illustrates the theorem.

Table 7.4. $p = 7$

7.2. **Selmer and Tate–Shafarevich Group Congruences.** Theorems 1.3 and 1.4 offer criteria for detecting elements in p-Selmer groups and Tate–Shafarevich groups of quadratic twists of certain elliptic curves. Theorem 1.3 assumes the truth of the Birch and Swinnerton-Dyer Conjecture. Theorem 1.4 is unconditional thanks to results of Skinner–Urban.

Here we offer data related to the curves E_{14} and E_{15}. In the notation of Theorem 1.4, we consider fundamental discriminants $-D$ such that $\left(\frac{-D}{p}\right) = -1$ and $\left(\frac{-D}{p'}\right) = 1$. For convenience let

$$\begin{aligned} H_{14}(D) &:= \delta_7(H(D) - \delta_7 H^{(2)}(D)), \\ \mathrm{tr}_2(D) &:= \mathrm{tr}(g_2|W_D), \\ \mathrm{Diff}_{14}(D) &:= H_{14}(D) - \mathrm{tr}_2(D), \end{aligned} \qquad \begin{aligned} H_{15}(D) &:= \delta_5(H(D) - \delta_5 H^{(3)}(D)), \\ \mathrm{tr}_3(D) &:= \mathrm{tr}(g_3|W_D), \\ \mathrm{Diff}_{15}(D) &:= H_{15}(D) - \mathrm{tr}_3(D). \end{aligned}$$

We have the following numerics. In Tables 7.5 and 7.6, the second and third columns offer graded traces and differences of class numbers. The fourth and fifth columns offer Mordell–Weil ranks and orders of Tate–Shafarevich groups assuming the Birch and Swinnerton-Dyer Conjecture. By Theorem 1.4, these columns are congruent if and only the corresponding p-Selmer group is nontrivial. First note that if these two columns are incongruent, then both the Mordell–Weil rank over $\mathbb{Q}$ and the p-part of the Tate–Shafarevich groups are trivial. However, when these columns are congruent, notice that either the rank is positive or the Tate–Shafarevich group is nontrivial at p.

The authors thank Drew Sutherland for computing the elliptic curve invariants in Tables 7.5 and 7.6.

Appendix A. The Character Table of *O'N*

Here we give the character table of the O'Nan group $O'N$ over the complex numbers. For $n \in \mathbb{N}$ we let $\zeta_n := e^{\frac{2\pi i}{n}}$ and define

$$A := \frac{1+3\sqrt{5}}{2}, \qquad B := \sqrt{2},$$
$$C := -\zeta_{19} - \zeta_{19}^{7} - \zeta_{19}^{8} - \zeta_{19}^{11} - \zeta_{19}^{12} - \zeta_{19}^{18},$$
$$D := -\zeta_{19}^{4} - \zeta_{19}^{6} - \zeta_{19}^{9} - \zeta_{19}^{10} - \zeta_{19}^{13} - \zeta_{19}^{15},$$
$$E := -\zeta_{19}^{2} - \zeta_{19}^{3} - \zeta_{19}^{5} - \zeta_{19}^{14} - \zeta_{19}^{16} - \zeta_{19}^{17},$$
$$F := i\sqrt{5}, \qquad G := \sqrt{7}, \qquad H := \frac{-1+i\sqrt{31}}{2}.$$

We use $\overline{A}$, $\overline{B}$, &c. to denote images under the obvious Galois involutions. Note that C, D, and E are in one Galois orbit as well, since

$$(X-C)(X-D)(X-E) = X^3 - X^2 - 6X + 7.$$

The character table is reproduced from Gap4 [50].

Table B.3. Multiplicities, part III.

Appendix C. Congruences

$\underline{p = 31}$:

$$0 \equiv F_{1A} - F_{31AB} \pmod{31}$$

$\underline{p = 19}$:

$$0 \equiv F_{1A} - F_{19ABC} \pmod{19}$$

$\underline{p = 11}$:

$$0 \equiv F_{1A} - F_{11A} \pmod{11}$$

$\underline{p = 7}$:

$$\begin{aligned} 0 &\equiv F_{1A} - F_{7AB} && \pmod{7^3} \\ &\equiv F_{2A} - F_{14A} && \pmod{7} \\ &\equiv F_{4AB} - F_{28AB} && \pmod{7} \end{aligned}$$

$\underline{p = 5}$:

$$\begin{aligned} 0 &\equiv F_{1A} - F_{5A} && \pmod{5^3} \\ &\equiv F_{2A} - F_{10A} && \pmod{5} \\ &\equiv F_{3A} - F_{15AB} && \pmod{5} \\ &\equiv F_{4AB} - F_{20AB} && \pmod{5} \end{aligned}$$

$\underline{p=3}$:

$$\begin{aligned}
0 &\equiv F_{1A} - F_{3A} && \pmod{3^5}\\
&\equiv F_{2A} - F_{6A} && \pmod{3^2}\\
&\equiv F_{4AB} - F_{12A} && \pmod{3^2}\\
&\equiv F_{5A} - F_{15AB} && \pmod{3^2}
\end{aligned}$$

$\underline{p=2}$:

$$\begin{aligned}
0 &\equiv F_{1A} + 303F_{2A} + 3024F_{4AB} + 4864F_{8AB} + 57344F_{16ABCD} && \pmod{2^{16}}\\
&\equiv F_{2A} + 7F_{4AB} + 8F_{8AB} + 112F_{16ABCD} && \pmod{2^7}\\
&\equiv F_{3A} + F_{6A} + 6F_{12A} && \pmod{2^3}\\
&\equiv F_{4AB} + F_{8AB} + 14F_{16ABCD} && \pmod{2^4}\\
&\equiv F_{5A} + F_{10A} + 6F_{20AB} && \pmod{2^3}\\
&\equiv F_{6A} + F_{12A} && \pmod{2}\\
&\equiv F_{7AB} + F_{14AB} && \pmod{2^3}\\
&\equiv F_{8AB} + 7F_{16ABCD} && \pmod{2^3}\\
&\equiv F_{10A} + F_{20AB} && \pmod{2}\\
&\equiv F_{14A} + F_{28AB} && \pmod{2}
\end{aligned}$$

Appendix D. Traces of Singular Moduli

We give the explicit descriptions of $F_{[g]}$ in terms of traces of singular moduli and class numbers as described in Section 5.

$$\begin{aligned}
F_{1A} &= \mathscr{T}^{(1)},\\
F_{2A} &= \mathscr{T}^{(2)} + 12\mathscr{H}^{(1)} - 12\mathscr{H}^{(2)},\\
F_{3A} &= \mathscr{T}^{(3)} + 12\mathscr{H}^{(1)} - 12\mathscr{H}^{(3)},\\
F_{4AB} &= \mathscr{T}^{(4)} + 12\mathscr{H}^{(2)} - 12\mathscr{H}^{(4)},\\
F_{5A} &= \mathscr{T}^{(5)} + 6\mathscr{H}^{(1)} - 6\mathscr{H}^{(5)},\\
F_{6A} &= \mathscr{T}^{(6)} - 12\mathscr{H}^{(1)} + 8\mathscr{H}^{(2)} + \frac{21}{2}\mathscr{H}^{(3)} - \frac{13}{2}\mathscr{H}^{(6)},\\
F_{7AB} &= \mathscr{T}^{(7)} + 4\mathscr{H}^{(1)} - 4\mathscr{H}^{(7)},\\
F_{8AB} &= \mathscr{T}^{(8)} + 4\mathscr{H}^{(4)} - 4\mathscr{H}^{(8)},\\
F_{10A} &= \mathscr{T}^{(10)} - 6\mathscr{H}^{(1)} + 4\mathscr{H}^{(2)} + \frac{11}{2}\mathscr{H}^{(5)} - \frac{7}{2}\mathscr{H}^{(10)},\\
F_{11A} &= \mathscr{T}^{(11,+)} + \frac{12}{5}\mathscr{H}^{(1)} - \frac{6}{5}\mathscr{H}^{(11)} - \frac{4}{5}\mathscr{G}^{(11)},\\
F_{12A} &= \mathscr{T}^{(12)} - 4\mathscr{H}^{(2)} + 4\mathscr{H}^{(4)} + \frac{5}{2}\mathscr{H}^{(6)} - \frac{5}{2}\mathscr{H}^{(12)},\\
F_{14A} &= \mathscr{T}^{(14,+)} - 4\mathscr{H}^{(1)} + \frac{8}{3}\mathscr{H}^{(2)} + \frac{15}{4}\mathscr{H}^{(7)} - \frac{41}{24}\mathscr{H}^{(14)} + \frac{8}{3}\mathscr{G}^{(14)},\\
F_{15AB} &= \mathscr{T}^{(15,+)} - 3\mathscr{H}^{(1)} + \frac{9}{4}\mathscr{H}^{(3)} + \frac{5}{2}\mathscr{H}^{(5)} - \frac{13}{8}\mathscr{H}^{(15)} + \frac{9}{4}\mathscr{G}^{(15)},\\
F_{16ABCD} &= 2\mathscr{T}^{(32,+)} - \mathscr{T}^{(16)} - 2\mathscr{H}^{(8)} + 4\mathscr{H}^{(16)} - \mathscr{H}^{(32)},\\
F_{19ABC} &= \mathscr{T}^{(19,+)} + \frac{4}{3}\mathscr{H}^{(1)} - \frac{2}{3}\mathscr{H}^{(19)} + \frac{4}{3}\mathscr{G}^{(19)},\\
F_{20AB} &= \mathscr{T}^{(20,+)} - 2\mathscr{H}^{(2)} + 2\mathscr{H}^{(4)} + \frac{3}{2}\mathscr{H}^{(10)} - \frac{3}{2}\mathscr{H}^{(20)},\\
F_{28AB} &= \mathscr{T}^{(28,+)} - \frac{4}{3}\mathscr{H}^{(2)} + \frac{4}{3}\mathscr{H}^{(4)} + \frac{25}{24}\mathscr{H}^{(14)} - \frac{25}{24}\mathscr{H}^{(28)} + \frac{8}{3}\mathscr{G}^{(28)},\\
F_{31AB} &= \mathscr{T}^{(31,+)} + \frac{4}{5}\mathscr{H}^{(1)} - \frac{2}{5}\mathscr{H}^{(31)} + \frac{3}{5}\mathscr{G}^{(31)}.
\end{aligned}$$

Here, $\mathscr{G}^{(N)}$ denotes the unique weight 3/2 cusp form for $\Gamma_0(4N)$ in the plus space with leading coefficient 1 if $N < 28$, $\mathscr{G}^{(28)}$ is the unique normalized cusp form in $S_{\frac{3}{2}}(\Gamma_0(28))$ hit with the V_4-operator, and $\mathscr{G}^{(31)} \in S_{\frac{3}{2}}^{+}(\Gamma_0(124))$ is the unique cusp form in this space satisfying

$$\mathscr{G}^{(31)}(\tau) = q^4 + \frac{11}{3}q^7 + O(q^8).$$

There is exactly one newform $f^{(31)}$ in $S^{+}_{\frac{3}{2}}(\Gamma_0(124))$ up to Galois conjugation and we have

$$f^{(31)}(\tau) = q^4 - \frac{1+\sqrt{5}}{2}q^7 - \frac{1-\sqrt{5}}{2}q^8 + \frac{1+\sqrt{5}}{2}q^{16} + O(q^{20}),$$

so that we can express $g^{(31)}$ in terms of this newform as follows,

$$\mathscr{G}^{(31)}(\tau) = \frac{3+5\sqrt{5}}{6}f^{(31)}(\tau) + \frac{3-5\sqrt{5}}{6}f^{(31)^{\sigma}}(\tau),$$

where, as in Table 5.2, a superscript σ denotes Galois conjugation.

Abstract

Preliminary Version
Comments and suggestions are welcome.

The word moonshine refers to unexpected relations between the two distinct mathematical structures: finite group representations and modular objects. It is believed that the key to understanding moonshine is through physical theories with special symmetries. Recent years have seen a varieties of new ways in which finite group representations and modular objects can be connected to each other, and these developments have brought promises and also puzzles into the string theory community.

These lecture notes aim to bring graduate students in theoretical physics and mathematical physics to the forefront of this active research area. In Part II of this note, we review the various cases of moonshine connections, ranging from the classical monstrous moonshine established in the last century to the most recent findings. In Part III, we discuss the relation between the moonshine connections and physics, especially string theory. After briefly reviewing a recent physical realisation of monstrous moonshine, we will describe in some details the mystery of the physical aspects of umbral moonshine, and also mention some other setups where string theory black holes can be connected to moonshine.

To make the exposition self-contained, we also provide the relevant background knowledge in Part I, including sections on finite groups, modular objects, and two-dimensional conformal field theories. This part occupies half of the pages of this set of notes and can be skipped by readers who are already familiar with the relevant concepts and techniques.

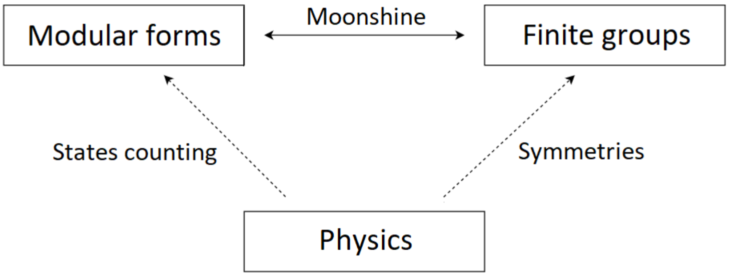
Introduction

The word moonshine is employed in mathematics to refer to an unexpected relationship between modular objects and representations of finite groups. The study of moonshine phenomenon has seen rapid developments in the past five years. While the relation is between two mathematical structures, it is expected that the existence of this surprising relation has its origin in physics, and in string theory in particular.



Moonshine: what, how and why?

Q: What is moonshine?

The structures of modular forms and that of finite group representations have a priori nothing to do with each other. The word moonshine refers to an unexpected relation between them. But this simple answer calls for more questions. Where does moonshine occur? What types of modular objects feature in moonshine relations? What types of finite groups can be represented by (mock) modular forms? In what ways? Is there a classification possible of such moonshine relations? Before satisfying answers to these questions can be found, the existence of moonshine relation remains to a large extent a mysterious phenomenon.

Q: How do moonshine relations arise?

In the classical cases of monstrous (and similarly Conway) moonshine, reviewed in §4, the relevant group representation has the structure of vertex operator algebra (VOA). In physical terms, these cases of moonshine can be can be thought of as being "explained" by the existence of certain special 2-dimensional conformal field theories (CFTs) that have the relevant finite groups as symmetry groups.

It would be very gratifying to have a similar physical construction for the finite group modules underlying umbral and other recently discovered moonshine relations. In certain "simpler" cases this has been achieved (cf. §5.2). Nevertheless, a uniform construction of the umbral moonshine module, reflecting the uniform structure among the twenty-three instances of umbral moonshine, is still absent. Similarly, the modules underlying the various other cases of new moonshines have not been constructed so far.

Apart from the question "what are these finite group modules?" there is also a deeper question of "what kind of (algebraic) structure do these moonshine modules possess?". The *mock* modular nature of the modular objects involved in the new cases of moonshine seems to suggest that a departure from the familiar unitary conformal field theories with discrete spectrum is necessary in order to accommodate the corresponding moonshine modules. However, the existence of generalised umbral moonshine (cf. §5.2) suggests that certain features resembling those of holomorphic orbifold CFTs should still be present in these new modules.

Last but not least, the first case of umbral moonshine, often referred to as the Mathieu moonshine, was uncovered in the context of string theory in the background of $K3$ surfaces. Subsequent development established the intimate relation between $K3$ string theory and all twenty-three instances of umbral moonshine. This relation to $K3$ string theory is the topic of §8.

To sum up, the origin of the classical monstrous moonshine can be understood as lying in the existence of certain special physical theory – certain 2d chiral CFTs and the corresponding string theory embedding to be more precise. See §4 and §7. The search for the origin of the newer cases of moonshine is still largely a challenging puzzle. However, one does expect the answer to again lie in certain physical theories, and most probably arises from the framework of string theory.

Q: Why should I care about moonshine?

Here are a few reasons why the authors, and many other mathematicians and physicists, care about moonshine phenomenon. First, theoretical physics is to a large extent about symmetries, and moonshine is to a large extent about hidden symmetries, which (conjecturally) take place in a physical context. There are therefore very good reasons for physicists to care about what is going on in moonshine. More generally speaking, the broad and interdisciplinary nature of the question and its connection to different areas in mathematics and theoretical physics suggests that the understanding of this mathematical paradigm is likely to spur novel developments in these areas, as was clearly true in the case of the classical monstrous moonshine. Here we highlight a few examples of such connections, in the context of recent developments:

- The discovery of umbral moonshine was initiated in the context of $K3$ string theory, arguably one of the most important examples of string theory compactifications. The development of umbral moonshine has led to new results in the study of automorphic forms and $K3$ geometry, especially in the context of string theory. We expect it to also shed light on the structure of BPS states and on other interesting aspects of the string landscape in the future. See §5.1, 5.2 and §8.

- The discovery of various new moonshine examples (cf. §6), involving various types of finite groups including an infinite family of them, poses a fascinating challenge for theoretical physics to accommodate the corresponding group representations. The solution of this (completely well-posed) puzzle is likely to point to novel structures in physics.

- The connection between certain new examples of moonshine and arithmetic geometry is interesting and constitutes a potentially fruitful path towards new perspectives in number theory. See §6.

Moreover, it is fascinating and puzzling why the two distinct structures of modular objects and finite groups are so deeply connected. An understanding of the true nature of these connections has the potential to change the way mathematicians think about these objects in a profound way.

About these lecture notes

The lecture note is written for the occasion of the TASI 2017 lectures on Moonshine given by the second author.

Acknowledgement

The second author would like to thank the organisers of the TASI 2017 school for giving her the opportunity to lecture in this very nice school. We would like to thank OUR FRIEND**A**, **B**..... for comments on an earlier version of the draft. Last but not least, the second author would like to thank Sarah Harrison, Jeff Harvey, Shamit Kachru, Natalie Paquette, Brandon Rayhaun, Roberto Volpato, Max Zimet, and in particular John Duncan for enjoyable collaborations on related topics, and for having taught me so much about this really fun subject!

Part I
Background

In the first part we briefly summarise the relevant background knowledge in moonshine study, including sections on finite groups, modular objects, and two-dimensional conformal field theories. This part can be safely skipped by readers who are familiar with these topics.

1 Finite groups and their representations

In this chapter we briefly review of basic notions of finite groups and their representations. We mainly follow [1–3] (see also [4]).

1.1 Groups

A group is a set G, together with a "multiplication" operation $\bullet : G \times G \to G$, formally denoted as $(G, \bullet)$. The symbol for this operation is usually implicit, and we often write ab for $a \bullet b$. A group must satisfy the following axioms:

1. **Closure:** $ab = c \in G$ for any $a, b \in G$.
2. **Associativity:** $(ab)c = a(bc)$ for any $a, b, c \in G$.
3. **Identity:** There exists a unique identity element $e \in G$, such that $eg = ge = g$ for any $g \in G$.
4. **Inverses:** For every $g \in G$, there exists a unique inverse element $g^{-1} \in G$, such that $gg^{-1} = g^{-1}g = e$. We also have that $e^{-1} = e$.

Notice that $ab \neq ba$ in general. In the case that $ab = ba$ for every $a, b \in G$, i.e. the group operation is commutative, the group is called *Abelian.* The number of elements of G is called the *order* of G, and it can be either finite or infinite. We also define the *order of an element*, $|g|$, to be the minimum number of times we need to multiply it with itself in order to reach the identity, i.e. $g^{|g|} = e$ (the order can also be infinite).

Next we give a brief summary of a few important notions of group theory.

Group homomorphisms. We say that a map $\phi : G \to F$ between two groups $(G, \bullet)$ and $(F, \star)$ is a *group homomorphism* if it preserves the group structure of G. In other words, ϕ must satisfy

$$\phi(a \bullet b) = \phi(a) \star \phi(b) \ , \tag{1.1}$$

for all $a, b \in G$. If there also exists the inverse homomorphic map $\phi^{-1} : F \to G$, then G and F are isomorphic; such groups are abstractly the same, but they may still have different realisations. An isomorphism $G \to G$ is called *automorphism*, and is often called a symmetry of G. The set of all automorphisms of G, denoted $\operatorname{Aut} G$, forms a group.

Conjugacy classes. Two group elements $a, b \in G$ are said to be conjugate to each other if there exists an element $g \in G$ such that $gag^{-1} = b$. In this case, we symbolically write $a \sim b$. Conjugation is an equivalence relation, since it is reflective ($a \sim a$), symmetric ($a \sim b$ iff $b \sim a$) and transitive (if $a \sim b$ and $b \sim c$ then $a \sim c$). Such a relation implies that G can be split into disjoint subsets $[a] \subset G$, called *conjugacy classes*, each containing all elements that are conjugate to each other:

$$[a] = \left\{ b \in G \mid gag^{-1} = b \;\; \text{for some} \;\; g \in G \right\} \ . \tag{1.2}$$

Obviously, a conjugacy class can be represented by any one of its elements, i.e. $[a] = [b]$ for all $b \sim a$. The number of distinct conjugacy classes is referred to as the *class number* of G, denoted here as $\mathrm{Cl}(G)$. All elements of a class have the same order. It is easy to see that an element constitutes a conjugacy class of its own if it commutes with all other elements of the group. As a result, in an Abelian group each class contains only one element and the class number equals the order of the group.

A common notation for conjugacy classes is writing the order of its elements, followed by an alphabetical letter. For example, $4A$ denotes a class of order four, $4B$ a different class of order four, $6A$ a class of order six, and so on. The identity is always a class of its own, namely $1A$, the unique class of order one.

Subgroups. A subgroup H is a subset $H \subset G$ which is itself a group, with the group structure inherited from G. Note that the identity element e always forms a subgroup $\{e\}$ of order 1, called the trivial subgroup. Subgroups H other than the trivial subgroup and G itself are called *proper subgroups* of G, and the notation $H < G$ is used for them (we use the notation $H \leq G$ if we can have $H = G$).

A *normal subgroup* N, also denoted as $N \triangleleft G$, is a subgroup of G that is invariant under conjugation by all elements of G:

$$N \triangleleft G \;\; \Leftrightarrow \;\; gNg^{-1} = N \text{ for all } g \in G \ . \tag{1.3}$$

As such, N is necessarily a union of conjugacy classes. A *maximal normal subgroup* of G is a normal subgroup which is not contained in any other normal subgroup of G, apart from G itself. Normal subgroups play a prominent role in quotient groups and group extensions (see below).

The centre $Z(G)$ of a group G is the set of all elements that commute with every other element, i.e.

$$Z(G) := \{a \in G \,|\, ab = ba \;\; \text{for all } b \in G\} \ . \tag{1.4}$$

The centre is always a normal subgroup of G. The *centralizer* of an element $g \in G$ is similarly defined by

$$C_G(g) = \{a \in G \,|\, ag = ga\}, \tag{1.5}$$

being the set of all elements that commute with g. Clearly, the centralizer of an element is always a subgroup of G.

Cosets. Let H be a subgroup of G, and take $g \in G$. We define the *left coset* of H in G with respect to g as the subset

$$gH = \{gh \mid h \in H\} \ . \tag{1.6}$$

The set of all left cosets of H in G is denoted by $G/H := \{gH \mid g \in G\}$. Similarly, the *right coset* of H in G with respect to g is defined as

$$Hg := \{hg \mid h \in H\} \ , \tag{1.7}$$

and the set of all right cosets of H in G is denoted by $H\backslash G := \{Hg \mid g \in G\}$. Notice that H is both a left and a right coset of itself, with respect to the identity $e \in G$.

One can more intuitively define left cosets in terms of an equivalence relation on G (not to be confused with conjugation); namely, for $a, b \in G$ we set $a \sim b$ iff $ah = b$ for some $h \in H$, i.e. a and b are related by multiplication of an element in H to the right. Then a, b represent the same equivalence class, which is exactly the coset $aH = bH$. All such classes make up G/H, which is viewed as a disjoint partition of G, as a set. Corresponding statements hold for right cosets. Some further facts about cosets:

- The number of left cosets is always equal to the number of right cosets, and is known as the *index* of H in G, denoted by $[G : H]$.
- If G is a finite group, then Lagrange's theorem states that the index equals the quotient of the order of G over the order of H, i.e. $[G : H]|H| = |G|$. This is indicatory of how G is partitioned under the coset equivalence relation associated with H.
- The left and the right cosets of H have the same number of elements, which is equal to the order of H.
- The left and right cosets of a normal subgroup coincide, as can be easily seen from its definition.

Quotient groups and group extensions. Cosets, like conjugacy classes, are in general not subgroups. However, given a normal subgroup N, the set G/N of right cosets (which coincides with the set of left cosets) inherits the group structure of G, and is called the *quotient group*. This can be seen by $(aN)(bN) = (ab)N$. The normal subgroup N can then be viewed as the kernel of the homomorphism $\psi : G \to G/N$. Note that in general G/N is not isomorphic to any subgroup of G. Moreover, the order of G/N is equal to the index $[G : N] = |G|/|N|$.

Consider now a *short exact sequence* of groups

$$1 \to M \xrightarrow{\phi} G \xrightarrow{\psi} Q \to 1 \ . \tag{1.8}$$

This means that $\phi(M)$, the embedding of M inside G, by ϕ is the kernel of the homomorphism ψ; in other words M is isomorphic to a normal subgroup $N \lhd G$, and $Q \cong G/N$. We then say that G is an *extension* of Q by M. An extension, as well as the corresponding sequence, is called *split* if there exists a homomorphism (embedding) $\widetilde{\psi} : Q \to G$ such that $\psi \circ \widetilde{\psi} = \mathrm{id}_Q$, the identity map on Q. We use the semi-direct product to denote such a split extension, $G = N \rtimes Q$. Otherwise, the extension is called *non-split*, and we write $G = N.Q$.

1.2 Classification of finite groups

From now on we focus on finite groups, which are groups with finite number of elements. The problem of classifying such groups can be reduced to the classification of a finite simple groups. A group is said to be *simple* if it has no proper normal subgroups. If G is not simple, then it can always be "decomposed" into a series of smaller groups, by considering quotients by maximal normal subgroups. To be precise, one can consider the *composition series*, which has the form

$$1 \lhd N_1 \lhd N_2 \lhd \cdots \lhd N_{n-1} \lhd N_n = G \ . \tag{1.9}$$

Here 1 denotes the trivial group, and every step of the series involves a maximal normal subgroup N_{i-1} of N_i, as well as the implied quotient group N_i/N_{i-1}. It can be shown that all the resulting quotient groups are simple, and the Jordan–Hölder theorem guarantees that for given G, two different composition series lead to the same simple groups. As a result, studying finite simple groups is to a large extent sufficient to understand general finite groups.

After a heroic effort spanning over half a century and involving more than 100 mathematicians leading to tens of thousands of pages of proof, all finite simple groups have been classified (see [5,6] for historical remarks). They belong to one of the following four categories: cyclic groups $\mathbb{Z}_p$ for prime p, alternating groups $\mathcal{A}_n$ ($n \geq 5$), 16 families of Lie type and 26 *sporadic groups*. Unlike the rest of finite simple groups, the 26 sporadic groups appear "sporadically" and are not part of infinite families. We will say more about the sporadic groups in the following section.

1.3 Sporadic groups and lattices

The largest sporadic group is the Fischer–Griess Monster group $\mathbb{M}$, which gets its name from its enormous size. The number of its element is

$$|\mathbb{M}| = 2^{46} \cdot 3^{20} \cdot 5^{9} \cdot 7^{6} \cdot 11^{2} \cdot 13^{3} \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71 \approx 8 \times 10^{53},$$

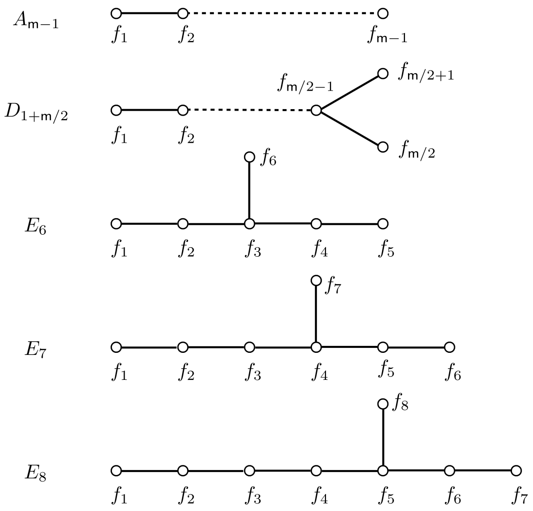
roughly the same as the number of atoms in the solar system. The Monster contains 20 of the 26 sporadic groups as its subgroups or quotients of subgroups, and these 20 is said to form 3 generations of a *happy family* by Robert Griess. In particular, the happy family includes the five Mathieu groups $M_{11}, M_{12}, M_{22}, M_{23}, M_{24}$. They are all subgroups of M_{24}, which is in turn a subgroup of the permutation group S_{24}, and are the the first sporadic groups to be discovered. The rest 6 which are not involved in the Monster are called the *pariahs* of sporadic groups.

The sporadic nature of the sporadic groups makes their existence somewhat mysterious and one might wonder what their "natural" representations are. An important hint is that many of the sporadic groups, especially those connected to the Monster, arise as subgroups of quotients of the automorphic groups of various special lattices. The appearance of moonshine involving sporadic groups sheds important light on the question, and the construction of moonshine often relies on the existence of these special lattices. As a result, in what follows we will briefly review the definition of lattices and their root systems, and introduce the special lattices relevant for moonshine.

Let V be a finite-dimensional real vector space of dimension r, equipped with an inner product $\langle \cdot, \cdot \rangle$. A finite subset $X \subset V$ of non-zero vectors is called a *root system of rank* r, if the following conditions are satisfied

- X spans V
- X is closed under reflections. Namely, $\beta - 2\dfrac{\langle \alpha, \beta \rangle}{\langle \alpha, \alpha \rangle}\alpha \in X$ for all $\alpha, \beta \in X$.

Figure 1: The ADE Dynkin diagrams.



- The only multiples of $\alpha \in X$ that belong to X are α and $-\alpha$.
- For all $\alpha, \beta \in X$, we have $\dfrac{2\langle\alpha,\beta\rangle}{\langle\alpha,\alpha\rangle} \in \mathbb{Z}$.

The elements $\alpha \in X$ of a root system are called *roots*. A root system X is said to be irreducible if it cannot be partitioned into proper orthogonal subsets $X = X_1 \cup X_2$. It turns out that the roots of such a system can have at most two possible lengths. If all roots have the same length, then the irreducible root system is called *simply-laced*. One can choose a subset Φ of roots $f_i \in X$ with $i = 1, \ldots, r$, such that each root can be written as an integral combination of $f_i \in \Phi$ with either all negative or all positive coefficients. Such a subset is called a set of *simple roots*, and is unique up to the action of the group generated by reflections with respect to all roots, called the *Weyl group* of X and denoted by $\mathrm{Weyl}(X)$.

To each irreducible root system we can attach a connected *Dynkin diagram*. Each simple root is associated with a node, and nodes associated to two distinct simple roots f_i, f_j are connected with N_{ij} lines, where

$$N_{ij} = \frac{2\langle f_i, f_j\rangle}{\langle f_i, f_i\rangle}\frac{2\langle f_j, f_i\rangle}{\langle f_j, f_j\rangle} \in \{0,1,2,3\}\ . \tag{1.10}$$

For simply-laced root systems we only have $N_{ij} \in \{0,1\}$. These correspond to the Dynkin diagrams of type A_n, D_n, E_6, E_7, E_8 with the subscript denoting the rank of the associated root system, as shown in figure 1.

Each irreducible root system contains a unique *highest root* θ with respect to a given set Φ of simple roots, whose decomposition

$$\theta = \sum_{i=1}^{r} a_i f_i \tag{1.11}$$

maximizes the sum $\sum a_i$. The *Coxeter number* of X is then defined by

$$m := 1 + \sum_{i=1}^{r} a_i\ . \tag{1.12}$$

The Coxeter number can also be defined in terms of $\mathrm{Weyl}(X)$. The product of reflections with respect to all simple roots $w = r_{f_1} r_{f_2} \cdots r_{f_r} \in W^X$ is called *Coxeter element*, and its order equals the Coxeter number m.

A *lattice* L of rank n is a free Abelian group isomorphic to the additive group $\mathbb{Z}^n$, equipped with a symmetric bilinear form $\langle \cdot, \cdot \rangle$. Embedding L into $\mathbb{R}^n$ gives the picture of a set of points inside the vector space $\mathbb{R}^n$. A few properties some lattices have that will be useful for us include the following:

- *Positive-definite*: the bilinear form induces a positive-definite inner product on $\mathbb{R}^n$.
- *Integral*: $\langle \lambda, \mu \rangle \in \mathbb{Z}$ for all $\lambda, \mu \in L$.
- *Even*: $\langle \lambda, \lambda \rangle \in 2\mathbb{Z}$ for all $\lambda \in L$.
- *Unimodular*: the dual lattice, defined by $L^* := \{\lambda \in L \otimes_{\mathbb{Z}} \mathbb{R} | \ \langle \lambda, L \rangle \subset \mathbb{Z}\}$, is isomorphic to the lattice itself.

All elements $\lambda \in L$ such that $\langle \lambda, \lambda \rangle = 2$ are called the *roots* of L.

Even, unimodular, positive-definite lattices in 24 dimensions play a distinguished role in several instances of moonshine, as we will discuss in the Part II and Part III of this note. It was proven by H. V. Niemeier in 1973 that there are only 24 inequivalent such lattices [7]. One of them, first discovered by J. Leech in 1967 and named the *Leech lattice*, is the only one of the 24 that has no root vectors [8–10]. The other 23, which we refer to as the *Niemeier lattices*, have non-trivial root systems. In fact, one useful construction of the Niemeier lattices is by combining the root lattices with the appropriate "glue vectors" [11]. It turns out that the 23 Niemeier lattices are uniquely labelled by the root systems X, called the *Niemeier root systems*, which are precisely one of the 23 unions of simply-laced (ADE) root systems $X = \cup_i Y_i$ satisfying the following conditions: 1) All components have the same Coxeter number, $\mathrm{Cox}(Y_i) = \mathrm{Cox}(Y_j)$; 2) the total rank equals the rank of the lattice $\sum_i \mathrm{rk}(Y_i) = 24$. Some examples out of the 23 include $24A_1$, $2A_{12}$, $8E_8$ and $D_{16}E_8$.

For each of these 24 even, unimodular, positive-definite lattices of rank 24 N we define a finite group

$$G_N := \mathrm{Aut}(N)/\mathrm{Weyl}(N), \tag{1.13}$$

where $\mathrm{Weyl}(N)$ denotes the Weyl group of the root system of N. In particular, when $N = \Lambda$ is the Leech lattice, the Weyl group $\mathrm{Weyl}(\Lambda)$ is the trivial group and $G_\Lambda \cong Co_0$ is the Conway group Co_0. By considering the quotients of this group and subgroups stabilising various structures we can obtain many of the sporadic groups. For instance, the sporadic simple group Co_1 is given by the quotient by the centre $Co_1 \cong Co_0/\{\pm 1\}$, and the Mathieu group M_{23} arises as the subgroup fixing a specific rank-2 sublattice. See Chapter 10 of [11] for a detailed discussion. If instead we choose N to be the Niemeier lattice with root system $24A_1$, for instance, the finite group $G_N \cong M_{24}$ is given by the largest Mathieu group. For the Niemeier lattice with root system $12A_2$, the finite group is $2.M_{12}$, the non-trivial extension of the Mathieu group M_{12}. These groups will play an important role in moonshine (cf. §4.2, §8.1, §5.2) and in the discussion of their physical context (cf. §8).

1.4 Representations of finite groups

The structure of groups is just what we need to describe symmetries. To put this into use we need the concept of representations of groups. In what follows we limit our discussion to *complex representations*, arising from group acting on a complex vector space V. More precisely, consider the group homomorphism $\rho : G \to GL(V)$. We can think of $\rho(g)$ as invertible $n \times n$ complex matrices. In particular we have $\rho\left(g^{-1}\right) = (\rho(g))^{-1}$. The vector space together with the map (V, ρ) is called a *representation* of dimension n. Often one refers to either V or ρ as the representation, while implicitly referring to the full data. The vector space V is also called a G-module in this context, and is said to carry a G-action. We say that the G-action is *faithful*, if no two distinct elements $g, g' \in G$ lead to $\rho(g) = \rho(g')$ (the corresponding representation is also called faithful).

Irreducible representations and dual representations. Given two representations (V, ρ) and (V', ρ') one can define their direct sum and their tensor product in a straightforward way, which leads to new representations $V \oplus V'$ and $V \otimes V'$.

Two representations ρ, ρ' are *equivalent* if there exists an invertible $n \times n$ matrix M such that $M\rho'(g) = \rho(g)M$ for all $g \in G$. A *subrepresentation* of a representation (V, ρ) is a representation (U, ρ'), where U is a subspace $U \subset V$ that is preserved by the action of G, and ρ' is the restriction of ρ to U. A representation V is said to be *irreducible* if it does not contain any proper subrepresentation, and *indecomposable* if it cannot be written as a direct sum of two (or more) non-zero subrepresentations. For finite groups, these two notions coincide. A representation is called *completely reducible* if it is a direct sum of finitely many irreducible representations, i.e. if it can be fully decomposed into irreducible pieces.

The so-called Maschke's theorem states that all (finite-dimensional) representations of a finite group are always completely reducible. There are two steps for proving this. First we show that a unitary representation is always completely reducible, by using the fact that given an inner product $\{\cdot, \cdot\} : V \times V \to \mathbb{C}$, the orthogonal complement of U in V is also a subrepresentation if U itself is a subrepresentation of V. Next we show that any representation is unitary with respect to the group-invariant inner product

$$\{v, w\} := \frac{1}{|G|} \sum_{g \in G} \langle \rho(g)v, \rho(g)w \rangle, \quad v, w \in V \ , \tag{1.14}$$

which then completes the proof.

We also mention the *dual representation* ρ^* of a representation ρ, defined by

$$\rho^*(g) := \left(\rho\left(g^{-1}\right)\right)^T \ , \quad g \in G \ , \tag{1.15}$$

which is the natural group action on the dual space $V^* = \mathrm{End}(V, \mathbb{C})$. Taking ρ to be unitary, we have $\rho^*(g) = \overline{\rho(g)}$. In other words, the dual representation is equivalent to the complex conjugate representation.

Characters. The character χ_ρ of a representation (V, ρ), with V a vector space over $\mathbb{C}$, is a map $G \to \mathbb{C}$ defined by the trace of the representation matrices,

$$\chi_\rho(g) := \mathrm{Tr}(\rho(g)) \ , \quad g \in G. \tag{1.16}$$

We will also often denote this trace by $\mathrm{Tr}_V\, g$. If ρ is irreducible, χ_ρ is called an irreducible character. Some properties of characters (for finite groups) are summarized below:

- The character is a *class function*, i.e. $\chi_\rho\left(hgh^{-1}\right) = \chi_\rho(g) \quad \forall\ g, h \in G$. This follows directly from the cyclic property of the trace.
- Two complex representations for a finite group have the same characters if and only if they are equivalent, which can be shown using the orthogonality property discussed below.
- The restriction of a character of G to a subgroup $H < G$ is a character of H.
- $\chi_\rho\left(g^{-1}\right) = \overline{\chi_\rho(g)}$, as follows from the fact that all eigenvalues of $\rho(g)$ are $|g|$-th roots of unity.
- For be two representations ρ, ρ' of G and $g \in G$, we have:

  $$\chi_{\rho\oplus\rho'}(g) = \chi_\rho(g) + \chi_{\rho'}(g)\ ,\quad \chi_{\rho\otimes\rho'}(g) = \chi_\rho(g)\chi_{\rho'}(g)\ ,\quad \chi_{\rho^*}(g) = \overline{\chi_\rho(g)}\ . \tag{1.17}$$

  This means that the characters form a commutative and associative algebra.

Orthogonality. Due to Schur's orthogonality relations (e.g. §4 of [2]), characters of unitary representations are equipped with a Hermitian inner product,

$$\langle \chi_\rho, \chi_{\rho'} \rangle = \frac{1}{|G|} \sum_{g\in G} \chi_\rho(g)\overline{\chi_{\rho'}(g)}\ . \tag{1.18}$$

When ρ and ρ' are irreducible representations, one can show that $\langle \chi_\rho, \chi_{\rho'} \rangle = 1$ if the two irreducible representations are equivalent, and it vanishes otherwise. As a result, characters of irreducible representations are orthonormal vectors in the space of class functions. In fact, it is possible to show that they span this space, from which one can conclude the important fact that the number of (inequivalent) irreducible representations equals the number of conjugacy classes (see for instance §3-7 of [1]). Moreover, one can show that there is another orthonormality property,

$$\sum_\rho \chi_\rho(g)\ \overline{\chi_\rho(h)} = \begin{cases} |C_G(g)|, & h \in [g] \\ 0, & \text{otherwise} \end{cases}\ , \tag{1.19}$$

where the sum is over inequivalent irreducible representations, and $|C_G(g)|$ denotes the order of the centralizer of $g \in G$, which is equal to the order of the group divided by the number of elements in the conjugacy class $[g]$.

Character table. We have already mentioned that the number of irreducible representations of a finite group G is equal to the number of conjugacy classes of G. We can group all characters of G into its *character table*, which is a square table of size $\mathrm{Cl}(G) \times \mathrm{Cl}(G)$, with rows labelling the different irreducible representations and columns labelling the different conjugacy classes. In other words, the (i, j) component of the character table is the character $\chi_i(g)$ of the i-th irreducible representation, evaluated at any g in the j-th conjugacy class . As an example, the character table for the alternating group $\mathcal{A}_6$ is displayed in Table 1. Note that there is an additional piece of information in the above table, the so-called power map. The row starting with sP gives the conjugacy classes $[g^s]$.

		1A	2A	3A	3B	4A	5A	5B
	2P	1A	1A	3A	3B	2A	5B	5A
	3P	1A	2A	1A	1A	4A	5B	5A

χ_1		1	1	1	1	1	1	1
χ_2		5	1	2	-1	-1	0	0
χ_3		5	1	-1	2	-1	0	0
χ_4		8	0	-1	-1	0	A	${}^*A$
χ_5		8	0	-1	-1	0	${}^*A$	A
χ_6		9	1	0	0	1	-1	-1
χ_7		10	-2	1	1	0	0	0

Table 1: Character table for $\mathcal{A}_6$, where $A = \frac{1-\sqrt{5}}{2}$ and ${}^*A = \frac{1+\sqrt{5}}{2}$.

Supermodules. We say that a G-module on a superspace ($\mathbb{Z}_2$-graded vector space) is a G-supermodule. Explicitly, if V is a G-supermodule it has the structure

$$V = V_{\underline{0}} \oplus V_{\underline{1}} \tag{1.20}$$

where $V_{\underline{0}}$ and $V_{\underline{1}}$ are both G-modules. We will sometimes refer to V as a *virtual representation* of G. The supertrace Str is defined to act with a minus sign on the odd subspaces: $\mathrm{Str}_V g := \mathrm{Tr}_{V_{\underline{0}}} g - \mathrm{Tr}_{V_{\underline{1}}} g$.

Cycle shapes and Frame shapes. As the name suggests, an N-dimensional *permutation representation* ρ_p of a group G has as its representation matrices $N \times N$ permutation matrices (all elements zero, apart from a single entry of 1 in each row and column). Given such a representation, to each conjugacy class in such a representation we can associate a *cycle shape*, which encodes the number and type of permutation cycles that elements of this class correspond to. A cycle shape has the general form

$$n_1^{\ell_1} n_2^{\ell_2} \cdots n_r^{\ell_r} \ , \quad \sum_{s=1}^{r} \ell_s n_s = N \ , \tag{1.21}$$

where n_s, ℓ_s are all positive integers, and n denotes an *n-cycle*, i.e. it represents a permutation of n elements. The exponents ℓ_s count the number of n_s-cycles. Clearly, an order k element can only have cycles of size n_s which divides k. Note that the cycle shapes can be read directly off the character table, including the power map.

More generally, we can define the *Frame shape* of $g \in G$ given any representation ρ, provided that all characters of ρ are rational numbers. Their rationality ensures that if λ is an eigenvalue of g, then λ^k is also an eigenvalue when k is co-prime to $|g|$ [12]. Denoting by $\lambda_1, \lambda_2, \ldots, \lambda_N$ the g-eigenvalues, then there exists a set of positive integers $i_1, i_2, \ldots, i_s$ and a set of non-zero integers $\ell_1, \ell_2, \ldots, \ell_s$ with the same cardinality such that

$$\det(\mathbf{1} - t\rho(g)) = \prod_{i=1}^{N} (1 - t\lambda_i) = \prod_{r=1}^{s} (1 - t^{i_r})^{\ell_r} \ . \tag{1.22}$$

Clearly one must have $\sum_{s=1}^{r} \ell_s i_s = N$ and we call $i_1^{\ell_1} i_2^{\ell_2} \cdots i_r^{\ell_r}$ the Frame shape of the conjugacy class $[g]$ for the representation ρ.

2 Modular objects

In this chapter we will briefly introduce the concept of modular forms and their extensions including mock modular forms, Jacobi forms, and mock Jacobi forms.

2.1 Modular forms

One of the standard references on modular forms, which we partially follow here, is [13]. It is well-known that $SL_2(\mathbb{R})$ acts on the upper-half plane $\mathbb{H} := \{\tau \in \mathbb{C} | \ \Im(\tau) > 0\}$ by a fractional linear (Möbius) transformation:

$$\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} : \mathbb{H} \to \mathbb{H} \ , \quad \tau \mapsto \gamma\tau := \frac{a\tau + b}{c\tau + d} \ . \tag{2.1}$$

In defining modular forms we consider discrete subgroups of $SL_2(\mathbb{R})$, an important example of which is the modular group $SL_2(\mathbb{Z})$. It is generated by

$$T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \tag{2.2}$$

satisfying $(ST)^3 = 1$ and $S^2 = -1$. We will also often work with $PSL_2(\mathbb{Z}) \cong SL_2(\mathbb{Z})/\{\pm 1\}$, which is also the mapping class group of the torus (cf. §3). We will often also consider the upper-half plane extended by adding the *cusps* $\{i\infty\} \cup \mathbb{Q}$, which $SL_2(\mathbb{Z})$ acts transitively on as one can see from $\gamma\infty = \frac{a}{c}$.

We start by defining weight zero modular forms on the modular group $SL_2(\mathbb{Z})$, which are simply holomorphic functions on $\mathbb{H}$ that are invariant under the action of $SL_2(\mathbb{Z})$:

$$f(\tau) = f(\gamma\tau) \quad \forall\, \gamma \in SL_2(\mathbb{Z}). \tag{2.3}$$

In particular, f has to be holomorphic as τ approaches the boundary of $\mathbb{H}$ at the cusps $\{i\infty\} \cup \mathbb{Q}$. But this turns out to be too restrictive: basic complex analysis tells us that constants are the only such functions. As a result, we would like to further generalise the above definition in the following directions:

1. *Analyticity*: the function is allowed to have exponential growth near the cusps. Such functions are said to be *weakly holomorphic modular forms.*

2. *Weights*: one allows for a scaling factor in the transformation rule. See (2.6).

3. *Other Groups*: one replaces $SL_2(\mathbb{Z})$ by a general $\Gamma < SL_2(\mathbb{R})$ in the transformation property (2.3).

4. *Multipliers*: one modifies the transformation rule (2.3) by allowing for a non-trivial character $\psi : SL_2(\mathbb{Z}) \to \mathbb{C}^*$. See (2.6).

5. *Vector-Valued*: instead of $f : \mathbb{H} \to \mathbb{C}$ we consider a vector-valued function $f : \mathbb{H} \to \mathbb{C}^n$ with n components.

Of course, the above generalisations can be combined. For instance one can consider a vector-valued modular form with multipliers for a subgroup Γ of $SL_2(\mathbb{R})$. Obviously, in the vector-valued case the character ψ is no longer a phase but a matrix. Also, the above concepts are not entirely independent. For instance, a component of a vector-valued modular form for $SL_2(\mathbb{Z})$ can be considered as a (single-valued) modular form for a subgroup of $SL_2(\mathbb{Z})$, and vice versa.

We will first start with the first generalisation and introduce the concept of *modular functions*. We say that $f : \mathbb{H} \to \mathbb{C}$ is a modular function if f is meromorphic in $\mathbb{H}$, satisfies the transformation rule (2.3), and grows like $e^{2\pi i \tau m}$ for some $m > -\infty$. In fact, modular functions form a function field with a single generator, called the *Hauptmodul* or *principal modulus*. This is because the fundamental domain $SL_2(\mathbb{Z})\backslash\mathbb{H}$ is a genus zero Riemann surface when finitely many points are added. Writing the upper-half plane with the cusps attached as $\hat{\mathbb{H}} = \mathbb{H} \cup \{i\infty\} \cup \mathbb{Q}$, the Hauptmodul has the property that it is an isomorphism between the two spheres $SL_2(\mathbb{Z})\backslash\hat{\mathbb{H}}$ and $\hat{\mathbb{C}}$. Clearly, such a Hauptmodul is unique up to Möbius transformations, or the choice of three points on the sphere. As a result, there is a unique Hauptmodul with the expansion

$$J(\tau) = q^{-1} + O(q) \tag{2.4}$$

near $\tau \to i\infty$. Here and in what follows we will write $q := \mathrm{e}(\tau)$, where $\mathrm{e}(x) := e^{2\pi i x}$ for $x \in \mathbb{C}$. In terms of the Eisenstein series and Dedekind eta function (cf. (2.7) and (2.19)), the J-function is given by

$$J(\tau) = j(\tau) - 744 = \frac{E_4^3(\tau)}{\eta^{24}(\tau)} - 744. \tag{2.5}$$

In general, a Hauptmodul can be defined as the generator of the field of modular functions for $\Gamma \le SL_2(\mathbb{R})$ whenever $\Gamma\backslash\hat{\mathbb{H}}$ is genus zero. These Hauptmoduls play an important role in moonshine.

Apart from the definition given above, there are three other equivalent ways of viewing modular functions. First, due to (2.3) we can view f as a function from the suitably compactified fundamental domain $SL_2(\mathbb{Z})\backslash\mathbb{H}$ to the Riemann sphere $\hat{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$. Second, due to the relation between $SL_2(\mathbb{Z})$ and rank two lattices we can associate to each τ a complex lattice $\Lambda_\tau := 1 \cdot \mathbb{Z} + \tau \cdot \mathbb{Z}$, and identify f as a function that associates to each such lattice Λ_τ a complex function $f(\tau)$, which is moreover invariant under a rescaling $\Lambda \mapsto \lambda\Lambda$, $\lambda \in \mathbb{C}$ of the lattice. The third way, which plays an important role in the a relation between modular forms and 2-dimensional conformal field theories, stems from the interpretation of $SL_2(\mathbb{Z})\backslash\mathbb{H}$ as the complex structure moduli space of a Riemann surface of genus one. This can be easily understood from the fact that a torus can be described as the complex plane modulo a rank two lattice, and is therefore up to a scale given by $\mathbb{C}/\Lambda_\tau$ for some $\tau \in \mathbb{H}$. The modular function can then be thought of as associating to each torus a complex number which only depends on its complex structure modulus τ. In this context, the group $PSL_2(\mathbb{Z}) := SL_2(\mathbb{Z})/\{\mathbb{1}, -\mathbb{1}\}$ plays the role of the mapping class group of a torus (cf. §3), where the $\mathbb{Z}_2 = \{\mathbb{1}, -\mathbb{1}\}$ central subgroup acts trivially on $\mathbb{H}$.

Next we turn to the second generalisation and introduce modular forms on the modular group $SL_2(\mathbb{Z})$ of a general weight k. They are defined as holomorphic functions on $\mathbb{H}$ that transform under the action of $SL_2(\mathbb{Z})$ as:

$$f(\tau) = (c\tau + d)^{-k} f\left(\frac{a\tau + b}{c\tau + d}\right) \quad \forall \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) \,. \tag{2.6}$$

From the lattice point of view, we consider complex functions f associated to a lattice Λ that scale like $f \mapsto \lambda^{-k} f$ under a rescaling $\Lambda \mapsto \lambda\Lambda$ of the lattice. We will consider integral and half-integral weight k.[1]

With this definition we start to get some non-trivial examples, even when holomorphicity at the cusps is required. For instance the following Eisenstein series:

$$\begin{aligned} E_4(\tau) &= 1 + 240 \sum_{n=1}^{\infty} \frac{n^3 q^n}{1-q^n} = 1 + 240\, q + 2160\, q^2 + \dots \ , \\ E_6(\tau) &= 1 - 504 \sum_{n=1}^{\infty} \frac{n^5 q^n}{1-q^n} = 1 - 504\, q - 16632\, q^2 + \dots \ , \end{aligned} \tag{2.7}$$

are examples of modular forms of weight 4 and weight 6, respectively. But the definition is still somewhat too restrictive as these two Eisenstein series are all there is: the ring of modular forms on $SL_2(\mathbb{Z})$ is generated freely by E_4 and E_6. Namely, any modular form of integral weight k can be written (uniquely) as a sum of monomials $E_4^{\alpha} E_6^{\beta}$ with $k = 4\alpha + 6\beta$. We denote the space of modular forms of weight k for group Γ by $M_k(\Gamma)$. Among modular forms, the so-called cusp forms are often of special interest. We say that a modular form f of weight k is a cusp form if $y^{k/2} f(x+iy)$ is bounded as $y \to \infty$. This condition guarantees that f has vanishing constants in its Fourier coefficients at all cusps.

In the third type of generalisation, we often encounter the $SL_2(\mathbb{Z})$ subgroups defined by the following congruences. For a positive integer N, we define

$$\Gamma_0(N) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) \ \mid c \equiv 0 \bmod N \right\} \ . \tag{2.8}$$

Below we will illustrate the generalisations above with some examples.

First we consider the Jacobi theta functions. Consider a 1-dimensional lattice with bilinear form $\langle x, x \rangle = x^2$. The associated theta function is

$$\theta_3(\tau) = \sum_{n \in \mathbb{Z}} q^{n^2/2} \, . \tag{2.9}$$

This simple function turns out to admit an expression in terms of infinite products

$$\theta_3(\tau) = \sum_{n \in \mathbb{Z}} q^{n^2/2} = \prod_{n=1}^{\infty} (1-q^n)(1+q^{n-1/2})^2 \ , \tag{2.10}$$

and has nice modular properties. To describe the modular properties, it is most natural to introduce another two theta functions,

$$\theta_2(\tau) = \sum_{n+\frac{1}{2} \in \mathbb{Z}} q^{n^2/2} = 2 q^{1/8} \prod_{n=1}^{\infty} (1-q^n)(1+q^n)^2 \ , \tag{2.11}$$

$$\theta_4(\tau) = \sum_{n \in \mathbb{Z}} (-1)^n q^{n^2/2} = \prod_{n=1}^{\infty} (1-q^n)(1-q^{n-1/2})^2 \ . \tag{2.12}$$

It turns out that they are the three components of a vector-valued modular form for $SL_2(\mathbb{Z})$

$$\Theta(\tau) := \begin{pmatrix} \theta_2(\tau) \\ \theta_3(\tau) \\ \theta_4(\tau) \end{pmatrix} , \quad \Theta(\tau) = \sqrt{\frac{i}{\tau}} \mathcal{S}\, \Theta\left(-\frac{1}{\tau}\right) = \mathcal{T}\, \Theta(\tau+1) \, , \tag{2.13}$$

---

[1] Clearly, special care needs to be taken when k is half-integral. Strictly speaking, one should work with the metaplectic double cover of $SL_2(\mathbb{Z})$. However we will avoid discussing the subtleties here as they will not cause any difficulty for us. We will refer the reader to [14] for more details.

where

$$\mathcal{S} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \mathcal{T} = \begin{pmatrix} e(-\frac{1}{8}) & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{2.14}$$

To illustrate the relation between vector-valued modular forms and modular forms for a congruence subgroup, consider $\theta(\tau) := \theta_3(2\tau)$. This transforms in the following way as a weight $1/2$ modular form for $\Gamma_0(4)$ with a non-trivial multiplier:

$$\theta(\tau) = \left(\frac{c}{d}\right) \epsilon_d \; (c\tau + d)^{-\frac{1}{2}} \; \theta(\gamma\tau) \tag{2.15}$$

for all $\gamma \in \Gamma_0(4)$, where

$$\epsilon_d := \begin{cases} 1 \, , & d \equiv 1 \bmod 4 \\ i \, , & d \equiv 3 \bmod 4 \end{cases}$$

and the Legendre symbol used above is defined as[2]

$$\left(\frac{\kappa}{\lambda}\right) := \begin{cases} +1 \, , & \text{if } \; \kappa \neq 0 \bmod \lambda \text{ and } \kappa \text{ is a quadratic residue modulo } \lambda \\ -1 \, , & \text{if } \; \kappa \neq 0 \bmod \lambda \text{ and } \kappa \text{ is not a quadratic residue modulo } \lambda \\ \;\; 0 \, , & \text{if } \; \kappa \equiv 0 \bmod \lambda \end{cases} .$$

Later we will see that these theta functions can be naturally considered as the specialisation at $z = 0$ of the two-variable Jacobi theta functions, defined either as infinite sums or infinite products:

$$\begin{aligned}
\theta_1(\tau, z) &= -i \sum_{n+\frac{1}{2}\in\mathbb{Z}} (-1)^{n-\frac{1}{2}} y^n q^{n^2/2} \\
&= -i q^{1/8} (y^{1/2} - y^{-1/2}) \prod_{n=1}^{\infty} (1-q^n)(1-yq^n)(1-y^{-1}q^n) \, , \\
\theta_2(\tau, z) &= \sum_{n+\frac{1}{2}\in\mathbb{Z}} y^n q^{n^2/2} \\
&= (y^{1/2} + y^{-1/2}) q^{1/8} \prod_{n=1}^{\infty} (1-q^n)(1+yq^n)(1+y^{-1}q^n) \, , \\
\theta_3(\tau, z) &= \sum_{n\in\mathbb{Z}} y^n q^{n^2/2} = \prod_{n=1}^{\infty} (1-q^n)(1+yq^{n-1/2})(1+y^{-1}q^{n-1/2}) \, , \\
\theta_4(\tau, z) &= \sum_{n\in\mathbb{Z}} (-1)^n y^n q^{n^2/2} = \prod_{n=1}^{\infty} (1-q^n)(1-yq^{n-1/2})(1-y^{-1}q^{n-1/2}) \quad .
\end{aligned}$$

They transform in the following way.

Let

$$\Theta(\tau, z) := \begin{pmatrix} \theta_1(\tau, z) \\ \theta_2(\tau, z) \\ \theta_3(\tau, z) \\ \theta_4(\tau, z) \end{pmatrix} \quad , \tag{2.16}$$

then we have (cf. §2.2),

$$\Theta(\tau, z) = \sqrt{\frac{i}{\tau}} \, e\big(-\frac{z^2}{2\tau}\big) \, \mathcal{S}' \, \Theta\big(-\frac{1}{\tau}, \frac{z}{\tau}\big) = \mathcal{T}' \, \Theta(\tau + 1, z) \, , \tag{2.17}$$

---

[2] κ is said to be a quadratic residue modulo λ if $\exists \; x \in \mathbb{Z}$ such that $x^2 \equiv \kappa \bmod \lambda$.

where

$$\mathcal{S}' = \begin{pmatrix} i & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad \mathcal{T}' = \begin{pmatrix} e(-1/8) & 0 & 0 & 0 \\ 0 & e(-1/8) & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}. \tag{2.18}$$

Another modular form one frequently encounters is the *Dedekind eta function*

$$\eta(\tau) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n) \ . \tag{2.19}$$

It is a weight 1/2 modular form with a non-trivial multiplier, satisfying

$$\eta(\tau) = \sqrt{\frac{i}{\tau}} \eta\big(-\frac{1}{\tau}\big), \quad \eta(\tau) = e\big(-\frac{1}{24}\big)\, \eta(\tau+1). \tag{2.20}$$

It is related to the theta functions by

$$\eta(\tau)^3 = \frac{1}{2} \theta_2(\tau)\theta_3(\tau)\theta_4(\tau). \tag{2.21}$$

Its 24-th power $\Delta := \eta^{24}$ is the familiar weight 12 cusp form for the modular group $SL_2(\mathbb{Z})$.

2.2 (Skew-)Holomorphic Jacobi forms

In this subsection we collect the definitions of (skew-)holomorphic Jacobi forms. These types of objects play a crucial role in moonshine and its connection to physics. This subsection, consisting mostly of definitions, follows §3.1 of [15] very closely.

We first define elliptic forms [16]. For m an integer define the index m *elliptic action* of the group $\mathbb{Z}^2$ on functions $\phi : \mathbb{H} \times \mathbb{C} \to \mathbb{C}$ by setting

$$(\phi|_m(\lambda, \mu))(\tau, z) := \mathrm{e}(m\lambda^2\tau + 2m\lambda z)\, \phi(\tau, z + \lambda\tau + \mu) \tag{2.22}$$

for $(\lambda, \mu) \in \mathbb{Z}^2$. Say that a smooth function $\phi : \mathbb{H} \times \mathbb{C} \to \mathbb{C}$ is an *elliptic form* of index m if $z \mapsto \phi(\tau, z)$ is holomorphic. Denote by $\mathcal{E}_m$ the space of elliptic forms of index m. Observe that any elliptic form $\phi \in \mathcal{E}_m$ admits a *theta-decomposition*

$$\phi(\tau, z) = \sum_{r \bmod 2m} h_r(\tau)\theta_{m,r}(\tau, z) \ , \tag{2.23}$$

where the theta series are given by

$$\theta_{m,r}(\tau, z) := \sum_{\ell = r \bmod 2m} q^{\ell^2/4m} y^{\ell} \ ,$$

for some $2m$ smooth functions $h_r : \mathbb{H} \to \mathbb{C}$. To see this, note from $\phi(\tau, z) = \phi(\tau, z+1)$ that we have $\phi(\tau, z) = \sum_{\ell \in \mathbb{Z}} c_\ell(\tau) y^\ell$ for some $c_\ell : \mathbb{H} \to \mathbb{C}$. Then the identity $\phi|_m(1, 0) = \phi$ implies that $c_r(\tau)q^{-r^2/4m}$ depends only on $r \bmod 2m$. The $2m$ functions $h_r(\tau) := c_r(\tau)q^{-r^2/4m}$ are precisely the theta-coefficients of ϕ in the theta-decomposition.

It will be convenient to regard h_r and $\theta_{m,r}$ in (2.23) as defining $2m$-vector-valued functions $h := (h_r)_{r \bmod 2m}$ and $\theta_m := (\theta_{m,r})_{r \bmod 2m}$. Then the theta-decomposition (2.23) may be more succinctly written as $\phi = h^t\theta_m$, where the superscript t denotes matrix transpose.

It follows from the Poisson summation formula that the vector-valued function $\theta_m = (\theta_{m,r})$ has the following behaviour under $SL_2(\mathbb{Z})$:

$$\theta_m\left(-\frac{1}{\tau},\frac{z}{\tau}\right)\frac{1}{\sqrt{\tau}}\,\mathrm{e}\left(-\frac{mz^2}{\tau}\right) = \mathcal{S}\theta_m(\tau,z), \quad \theta_m(\tau+1,z) = \mathcal{T}\theta_m(\tau,z), \tag{2.24}$$

where $\mathcal{S} = (\mathcal{S}_{rr'})$ and $\mathcal{T} = (\mathcal{T}_{rr'})$ are unitary matrices defined for a fixed positive integer m, given by $\mathcal{S}_{rr'} := \frac{1}{\sqrt{2m}}\,\mathrm{e}\left(-\frac{1}{8}-\frac{rr'}{2m}\right)$ and $\mathcal{T}_{rr'} := \mathrm{e}\left(\frac{r^2}{4m}\right)\delta_{r,r'}$. (Cf. e.g. §5 of [17].) This suggests that we obtain elliptic forms $\phi = h^t\theta_m \in \mathcal{E}_m$ with good modular transformation properties $SL_2(\mathbb{Z})$ by requiring suitable conditions on h.

To formulate these notions precisely, define the weight k *modular*, and *skew-modular* actions of $SL_2(\mathbb{Z})$ on $\mathcal{E}_m$, for k and m integers, by setting

$$\begin{aligned}(\phi|_{k,m}\gamma)(\tau,z) &:= \phi\left(\frac{a\tau+b}{c\tau+d},\frac{z}{c\tau+d}\right)\frac{1}{(c\tau+d)^k}\,\mathrm{e}\left(-\frac{cmz^2}{c\tau+d}\right)\\ (\phi|^{\mathrm{sk}}_{k,m}\gamma)(\tau,z) &:= \phi\left(\frac{a\tau+b}{c\tau+d},\frac{z}{c\tau+d}\right)\frac{1}{(c\bar\tau+d)^k}\frac{c\bar\tau+d}{|c\tau+d|}\,\mathrm{e}\left(-\frac{cmz^2}{c\tau+d}\right)\ ,\end{aligned} \tag{2.25}$$

for $\phi \in \mathcal{E}_m$ and $\gamma = \left(\begin{smallmatrix} a & b\\ c & d\end{smallmatrix}\right) \in SL_2(\mathbb{Z})$.

Roughly speaking, a Jacobi form of weight k and index m is an elliptic form $\phi(\tau,z)$, holomorphic in the τ-variable, which is moreover invariant under $|_{k,m}\gamma$ for all $\gamma \in SL_2(\mathbb{Z})$. Note that $\phi|_{k,m}\left(\begin{smallmatrix} 1 & 1\\ 0 & 1\end{smallmatrix}\right) = \phi$ implies the expansion

$$\phi(\tau,z) = \sum_{\substack{D,\ell\in\mathbb{Z}\\ D=\ell^2 \bmod 4m}} C_\phi(D,\ell)q^{-D/4m}q^{\ell^2/4m}y^\ell\ , \tag{2.26}$$

where $C_\phi(D,\ell)$ depends only on $\ell \bmod 2m$, corresponding to the theta decomposition

$$h_r(\tau) = \sum_{\substack{D\in\mathbb{Z}\\ D=r^2 \bmod 4m}} C_\phi(D,r)q^{-D/4m}\ . \tag{2.27}$$

The invariance under $SL_2(\mathbb{Z})$ of $\phi = h^t\theta_m$ leads to the modularity of the vector-valued function $h = (h_r)$. In other words, $h = (h_r)$ transforms as a vector-valued modular form and contains precisely the same information as the Jacobi form. To complete the definition, we also need to specify the growth behaviour of $h(\tau)$ near the cusp. We say that $\phi \in \mathcal{E}_m$, invariant under $|_{k,m}\gamma$ for all $\gamma \in SL_2(\mathbb{Z})$, is a *weak holomorphic/holomorphic/cuspidal holomorphic Jacobi form* if the Fourier coefficients satisfy $C_\phi(D,r) = 0$ unless $-D + r'^2 \geq 0$ for all $r' = r \bmod 2m$, $C_\phi(D,r) = 0$ for $D > 0$, or $C_\phi(D,r) = 0$ for $D \geq 0$, respectively. We denote the space of weak holomorphic Jacobi forms of weight k and index m by $J^{\mathrm{wk}}_{k,m}$. Notice that, at odd weight, applying (2.25) to the case $\gamma = -\left(\begin{smallmatrix} 1 & 0\\ 0 & 1\end{smallmatrix}\right)$ shows that the Jacobi form must be odd under $z \leftrightarrow -z$. It will therefore be convenient to introduce

$$\hat\theta_{m,r} = \theta_{m,r} - \theta_{m,-r}\ . \tag{2.28}$$

We now turn to the closely related skew-holomorphic Jacobi forms. An elliptic form $\phi \in \mathcal{E}_m$ is called a *weak skew-holomorphic Jacobi form* if it meets the following conditions. First, its theta-coefficients are anti-holomorphic functions on $\mathbb{H}$; second, it is invariant for the weight k skew-modular action (2.25), so that $\phi|^{\mathrm{sk}}_{k,m}\gamma = \phi$ for all $\gamma \in SL_2(\mathbb{Z})$; finally, $\tau \mapsto \phi(\tau, z)$ remains bounded as $\Im(\tau) \to \infty$ for fixed $z \in \mathbb{C}$. Thus a weak skew-holomorphic Jacobi form admits a Fourier expansion of the form

$$\phi(\tau, z) = \sum_{\substack{D,\ell \in \mathbb{Z} \\ D=\ell^2 \bmod 4m}} C_\phi(D, \ell)\, \bar{q}^{D/4m} q^{\ell^2/4m} y^\ell \ , \tag{2.29}$$

for some $2m$ functions $D \mapsto C_\phi(D, r)$, and we recover its theta-coefficients by writing

$$h_r(\tau) = \sum_{\substack{D \in \mathbb{Z} \\ D=r^2 \bmod 4m}} C_\phi(D, r) \bar{q}^{D/4m} \ . \tag{2.30}$$

A weak skew-holomorphic Jacobi form ϕ is called a *skew-holomorphic Jacobi form*, or a *cuspidal skew-holomorphic Jacobi form*, when the Fourier coefficients satisfy $C_\phi(D, r) = 0$ for $D < 0$, or $C_\phi(D, r) = 0$ for $D \leq 0$, respectively.

We will close this subsection with some examples.

- Define

  $$\begin{aligned} \phi_{0,1}(\tau, z) &= 4 \sum_{i=2,3,4} \Big(\frac{\theta_i(\tau, z)}{\theta_i(\tau, 0)}\Big)^2 \ , \\ \phi_{-2,1} &= -\frac{\theta_1(\tau, z)^2}{\eta^6(\tau)} \ . \end{aligned} \tag{2.31}$$

  The ring of weak Jacobi forms of even weight is freely generated by $\phi_{0,1}$ and $\phi_{-2,1}$ over the ring of modular forms for $SL_2(\mathbb{Z})$:

  $$J^{\rm wk}_{2k,m} = \sum_{j=0}^{m} M_{2k+2j}(SL_2(\mathbb{Z}))\, \phi_{-2,1}^j \phi_{0,1}^{m-j} \ . \tag{2.32}$$

  The function $\phi_{0,1}$ plays an important role in Mathieu and umbral moonshine, since $2\phi_{0,1}$ coincides with the $K3$ elliptic genus $\mathbf{EG}(\tau, z; K3)$. See §3.3 for a definition of the elliptic genus.

- In [18] it was shown that the modified elliptic genus of the so-called MSW string [19] involves a skew-holomorphic Jacobi form with index specified by the charges of the black hole, provided that the moduli is fixed at their black hole attractor value. See §9 for more discussions on this.

  As a concrete example, consider a single M5 brane wrapping $\mathbb{P}^2$. The modified elliptic genus of the resulting effective string is given by $\frac{1}{2\eta^6(\tau)} \overline{t_{2,2}(\tau, \frac{\bar{z}}{2})}$, where

  $$t_{2,2}(\tau, z) = \sum_{r \bmod 4} \overline{\theta^1_{2,r}(\tau)} \theta_{2,r}(\tau, z)$$

  is a weight 2 skew-holomorphic Jacobi forms. In the above we have used the definition

  $$\theta^1_{m,r}(\tau) := \frac{1}{2\pi i} \frac{\partial}{\partial z} \theta_{m,r}(\tau, z)|_{z=0} \ . \tag{2.33}$$

  Note that $\theta^1_{2,1}(\tau) = -\theta^1_{2,-1}(\tau) = \eta^3(\tau)$ coincides with the shadow of the Mathieu moonshine function (2.42).

2.3 Mock modular forms

In this section we introduce mock modular forms and the closely related concept of mock Jacobi forms. We follow the treatment of §7.1 of [16] and §3.2 of [15] closely. The subject, initiated by the legendary mathematician Srinivasa Ramanujan, has a fascinating history. We recommend [20] for a short account of it.

Let $w \in \frac{1}{2}\mathbb{Z}$ and let h be a holomorphic function on $\mathbb{H}$ with at most exponential growth at all cusps. We say that h is a (weakly holomorphic) mock modular form of weight w for a discrete subgroup $\Gamma \leq SL_2(\mathbb{R})$ if there is a modular form g of weight $2-w$ such that the sum $\hat{h} := h + g^*$ transforms like a holomorphic modular form of weigh w for Γ. Moreover, we say that g is the *shadow* of the mock modular form h and $\hat{h}$ is its *completion*. In the above we have used the following definition of g^*. Writing the Fourier expansion of g as $g(\tau) = \sum_{n\geq 0} c_g(n)q^n$, then

$$g^*(\tau) := \overline{c_g(0)}\frac{(-\Im(\tau))^{1-w}}{w-1} + \sum_{n>0}(-4\pi n)^{w-1}\overline{c_g(n)}q^{-n}\Gamma(1-w, 4\pi n\Im(\tau)) \ , \tag{2.34}$$

where $\Gamma(1-w,x) = \int_x^\infty e^{-t}t^w dt$ denotes the incomplete gamma function. When $c_g(0) = 0$, the above coincides with the so-called *non-holomorphic weight w Eichler integral* of g, given by

$$g^*(\tau) := (-2)^{w-1}\,\mathrm{e}(\tfrac{w-1}{4})\int_{-\bar{\tau}}^{\infty}(\tau' + \tau)^{-w}\overline{g(-\overline{\tau'})}\mathrm{d}\tau' \ . \tag{2.35}$$

Note that

$$-2i\Im(\tau)^w\frac{\partial}{\partial\bar{\tau}}g^*(\tau) = \overline{g(\tau)} \ , \tag{2.36}$$

and hence $\hat{h}$ is annihilated by the weight w Laplacian $\Delta_w := \Im(\tau)^{2-w}\partial_\tau\Im(\tau)^w\partial_{\bar{\tau}}$. Such functions are called harmonic Maass forms, and one can identify h as the (uniquely defined) holomorphic part of the harmonic Maass form $\hat{h}$. Finally, note that from (2.34) it is obvious that the harmonic Maass form $\hat{h}$ transforms with a multiplier which is the inverse of that of the modular form g.

Just as in the case of usual modular forms, one can generalise the above definition of mock modular forms in various directions, including incorporating non-trivial multiplier systems and considering vector-valued mock modular forms. Next we turn our attention to a specific type of vector-valued mock modular forms, namely those arising from the so-called mock Jacobi forms. For integers k and m, we say that an elliptic form $\phi \in \mathcal{E}_m$ is a *weak mock Jacobi form* of weight k and index m if the following is true. Write the theta-decomposition of ϕ as $\phi = \sum_r h_r\theta_{m,r}$. First, $\tau \mapsto \phi(\tau, z)$ is bounded as $\Im(\tau) \to \infty$ for every fixed $z \in \mathbb{C}$; second, all the h_r are holomorphic; finally, there exists a skew-holomorphic Jacobi form $\sigma = \sum_r \overline{g_r}\theta_{m,r} \in S^{\mathrm{sk}}_{3-k,m}$, such that $\hat{\phi} := \sum_r \hat{h}_r\theta_{m,r}$ is invariant for the weight k modular action $|_{k,m}$ of $SL_2(\mathbb{Z})$ on $\mathcal{E}_m$ (cf. (2.25)) with the definition

$$\hat{h}_r(\tau) := h_r(\tau) + \frac{1}{\sqrt{2m}}g^*_r(\tau) \ . \tag{2.37}$$

As discussed in [21] and analysed carefully in [16, 22], meromorphic Jacobi forms – what one obtains when relaxing the condition on Jacobi forms to allow for poles at torsion points $z \in \mathbb{Q} + \mathbb{Q}\tau$ – naturally give rise to mock Jacobi forms. In particular, all the mock Jacobi forms featured in umbral moonshine can be viewed as arising from meromorphic Jacobi forms.

From a physical point of view, as demonstrated in a series of recent works, the "mockness" of these mock modular objects is often related to the non-compactness of relevant spaces in the theory. See, for instance, [16,23–26]. Let us take 2d CFTs with a non-compact target space as an example. The non-compactness of the target space often lead to a continuous part of the spectrum. In this case the standard CFT arguments might fail. In particular there could be imperfect pairing between the bosonic and fermionic states in the continuous part of the spectrum and we could end up with a non-holomorphic BPS index, given by the completion of a mock modular object, as a result. See for instance [24,27–31] for details for some specific examples, and see the remark at the end of §3.3 for a more detailed discussion in the context of elliptic genus. Another context in which non-compactness appears and leads to a role for mock modular forms is wall-crossing (when approaching the wall, the distance of the bound black hole centers goes to infinity). The BPS counting of the black hole microstates hence depends on the moduli and correspondingly the countour of integration [32], and the result of the integration is mock modular [16].

Another source of mock modular forms in physics is the characters of supersymmetric infinite algebras, such as the $\mathcal{N}=2$ and $\mathcal{N}=4$ superconformal algebras mentioned in §8.1. Some more examples can be found in for instance [33] and references therein. Interestingly, as we will explain in §8.2, the mockness of the mock modular form in (2.42) can be seen as either arising from CFT with non-compact target space or as a result to the mockness of characters of the $\mathcal{N}=4$ superconformal algebra.

We will end this subsection with a few examples.

- Ramanujan wrote down the following simple-looking Eulerian series in his 1920 letter to Hardy [34],

$$\chi_0(q)=\sum_{n=0}^{\infty}\frac{q^n}{(1-q^{n+1})(1-q^{n+2})\dots(1-q^{2n})}=1+q+q^2+2\,q^3+\dots\ ,$$
$$\chi_1(q)=\sum_{n=0}^{\infty}\frac{q^n}{(1-q^{n+1})(1-q^{n+2})\dots(1-q^{2n})(1-q^{2n+1})}=1+2\,q+2\,q^2+3\,q^3+\dots\ ,$$

as two of the examples of his *mock theta functions* (of order 5). In fact, they are closely related to mock Jacobi forms.

Define $I^{3E_8}=\{1,7\}$, $A=\{1,11,19,29\}$, and

$$H_1^{3E_8}(\tau)=q^{-1/120}(2\chi_0(q)-4)\ ,\quad H_7^{3E_8}(\tau)=2q^{71/120}\chi_1(q), \tag{2.38}$$

then $(H_r^{3E_8})_{r\in I^{3E_8}}$ is a vector-valued mock modular form of weight 1/2 for the modular group. Its shadow is given by the index 30 theta functions

$$g_r^{3E_8}=3\sum_{a\in A}\theta^1_{30,a\,r}. \tag{2.39}$$

Writing $\hat{H}_r^{3E_8}(\tau)=H_r^{3E_8}+(g_r^{3E_8})^*$, we have

$$\begin{pmatrix}\hat{H}_1^{3E_8}\\ \hat{H}_7^{3E_8}\end{pmatrix}(\tau+1)=\begin{pmatrix}\mathrm{e}(-\frac{1}{120}) & 0\\ 0 & \mathrm{e}(-\frac{49}{120})\end{pmatrix}\begin{pmatrix}\hat{H}_1^{3E_8}\\ \hat{H}_7^{3E_8}\end{pmatrix}(\tau) \tag{2.40}$$

and

$$\begin{pmatrix} \hat{H}^{3E_8}_1 \\ \hat{H}^{3E_8}_7 \end{pmatrix} \left(-\frac{1}{\tau}\right) = \tau^{1/2} i^{3/2} \begin{pmatrix} \frac{1}{2}\sqrt{1-\frac{1}{\sqrt{5}}} & \frac{1}{2}\sqrt{1+\frac{1}{\sqrt{5}}} \\ \frac{1}{2}\sqrt{1-\frac{1}{\sqrt{5}}} & -\frac{1}{2}\sqrt{1-\frac{1}{\sqrt{5}}} \end{pmatrix} \begin{pmatrix} \hat{H}^{3E_8}_1 \\ \hat{H}^{3E_8}_7 \end{pmatrix} (\tau) \quad (2.41)$$

Moreover, $H^{3E_8}_i$ can be viewed as arising from the theta composition of the mock Jacobi form $\psi^{3E_8}(\tau,z) := \sum_{r\in I^{3E_8}} H^{3E_8}_r \sum_{a\in A} \hat{\theta}^{3E_8}_{a\,r}$. More specifically, $\hat{\psi}^{3E_8}(\tau,z) := \sum_{r\in I^{3E_8}} \hat{H}^{3E_8}_r \sum_{a\in A} \hat{\theta}^{3E_8}_{a\,r}$ is non-holomorphic in τ and transforms as a Jacobi form of weight 1 and index 30. As the notation suggests, $H^{3E_8}_r$ encodes the graded dimension of the umbral moonshine module underlying the case of umbral moonshine corresponding to Niemeier lattice N with root system $3E_8$, as we will discuss in §5.2.

- Let $H : \mathbb{H} \to \mathbb{C}$ be given by

$$H(\tau) = \frac{-2E_2(\tau) + 48F^{(2)}_2(\tau)}{\eta(\tau)^3} = 2q^{-\frac{1}{8}}\left(-1 + 45\,q + 231\,q^2 + 770\,q^3 \ldots\right) \;, \quad (2.42)$$

where

$$E_2 = 1 - 24\sum_{n=1}^{\infty} \frac{nq^n}{1-q^n}$$

is the weight two Eisenstein series (which is not a modular form) and

$$F^{(2)}_2(\tau) = \sum_{\substack{r>s>0 \\ r-s=1 \bmod 2}} (-1)^r\, s\, q^{rs/2} = q + q^2 - q^3 + q^4 + \ldots \;.$$

Note that the first few Fourier coefficients of $H/2$: 45, 231 770, 2277 , 5796, coincide with dimensions of certain irreducible representations of the sporadic group M_{24}! Indeed, in umbral moonshine $H = H^{24A_1}$ plays the role of the graded dimensions of the underlying M_{24}-module. See 5.1.

This function is a mock modular form with shadow $24\eta^3(\tau)$ (and therefore with a multiplier given by the inverse of that of $\eta^3(\tau)$). In other words,

$$\hat{H}(\tau) = H(\tau) + 24\,(4i)^{-1/2}\int_{-\bar{\tau}}^{\infty} (z+\tau)^{-1/2}\overline{\eta(-\bar{z})^3}\mathrm{d}z, \quad (2.43)$$

transforms as a weight 1/2 modular form for the modular group $SL_2(\mathbb{Z})$.

Moreover, the two-variable function $\psi^{24A_1}(\tau,z) := H(\tau)(\theta_{2,1} - \theta_{2,-1})(\tau,z)$ is a mock Jacobi form of weight one and index two. This mock Jacobi form can be seen as arising from a meromorphic Jacobi form by subtracting its "polar part". To see this, consider the weight one index two meromorphic Jacobi form

$$\psi(\tau,z) := -2i\frac{\theta_1(\tau,2z)\eta^3(\tau)}{\theta_1^2(\tau,z)}\phi_{0,1}(\tau,z) = -i\frac{\theta_1(\tau,2z)\eta^3(\tau)}{\theta_1^2(\tau,z)}\mathbf{EG}(\tau,z;K3) \;, \quad (2.44)$$

(cf. (2.31)) which has a simple pole at $z \in \mathbb{Z}+\mathbb{Z}\tau$. Then the following identity holds,

$$\psi(\tau,z) = \psi^{24A_1}(\tau,z) - 24\,\mathrm{Av}^{(2)}\left[\frac{y+1}{y-1}\right] \;. \quad (2.45)$$

In the above $\mathrm{Av}^{(m)}$ denotes the index-m averaging operator

$$\mathrm{Av}^{(m)}[F(y)] = \sum_{k\in\mathbb{Z}} q^{mk^2} y^{2mk} F(q^k y) \ ,$$

with the elliptic symmetry $\mathrm{Av}^{(m)}[F(y)]|_m(\lambda,\mu) = \mathrm{Av}^{(m)}[F(y)]$ for all $\lambda, \mu \in \mathbb{Z}$, and the second term in (2.45) can be interpreted as the canonical "polar part" of the meromorphic Jacobi form φ.

- Consider the set of binary quadratic forms with discriminant D,

  $$\mathcal{Q}_D := \{Q[X,Y] = AX^2 + BXY + CY^2 | B^2 - 4AC = D\} \ . \tag{2.46}$$

  This has a natural action of $SL_2(\mathbb{Z})$, and we are interested in elements in $\mathcal{Q}_D$ that are not equivalent under the modular group action. For instance, an interesting number is the *Hurwitz-Kronecker class number*

  $$H(D) := \sum_{Q\in\mathcal{Q}_D \backslash SL_2(\mathbb{Z})} \frac{1}{\omega_Q} \ , \tag{2.47}$$

  where ω_Q denotes the order of the $SL_2(\mathbb{Z})$-subgroup that leaves Q invariant. It takes values in $\{1, 2, 3\}$. Roughly speaking, this number counts the number of inequivalent quadratic forms with discriminant D, and will play an important role in §6 and §9.

  To each $Q \in \mathcal{Q}_D$ there is a unique root α_D (satisfying $Q[1, \alpha_D] = 0$) in the upper-half plane. Clearly, $J(\alpha_Q)$ is independent of which representative of Q one picks in the $SL_2(\mathbb{Z})$-orbit and one can similarly define weighted sums like (2.47), but now involving values of polynomials of J evaluated at α_Q, referred to as the *traces of singular moduli.* The generating functions of such quantities (summing over D with the grading factor q^{cD} for some c) will turn out to have interesting modular properties.

  For instance, the following generating of the Hurwitz-Kronecker class number, extended by $H(0) = -\frac{1}{12}$,

  $$\mathcal{H}(\tau) := \sum_{D\leq 0} H(D) q^{|D|} = -\frac{1}{12} + \frac{1}{3}q^3 + \frac{1}{2}q^4 + q^7 + q^8 + \dots \tag{2.48}$$

  is a mock modular form of weight $\frac{3}{2}$ for $\Gamma_0(4)$, with shadow given by the theta function $\theta(\tau)$ (see §2.1). The mock modularity property of this function is realised very early on in [35]. This form also has the interesting feature that it is bounded at all cusps and hence has slow growth in its Fourier coefficients, corresponding to the subtle growth of the class numbers.

  The physical relevance of this function will be mentioned in §9. This is in fact perhaps the first mock modular form which was found to play a role in physic [36, 37].

3 Conformal field theory in 2 dimensions

This chapter gives a brief summary of some key ingredients of 2-dimensional conformal field theories (CFTs), and is in no way meant as a complete exposition. CFTs are relevant for moonshine, since in the cases that are known so far the corresponding moonshine modules feature vertex operator algebra (VOA) structures, which capture the structure of the chiral algebra of a 2d CFT. Instead of the more formal VOA language, we opt for the CFT language more familiar to physicists. References on the basic knowledge of CFT include [38–41]. See also Professor Xi Yin's TASI lecture notes in this volume [42].

After the general summary of the basic structure in §3.1, we quickly review aspects of (holomorphic) orbifolds that are relevant for moonshine, in particular for the understanding of the modular properties of the moonshine functions. After that we focus on supersymmetric conformal field theories and introduce the so-called elliptic genus, counting BPS states, that will play an important role in the discussion of the physical context of Mathieu and umbral moonshine (§8).

3.1 General structure

A conformal field theory is a quantum field theory with conformal symmetry. Conformal transformations are coordinate transformations that preserve the conformal flatness of the metric. Focusing on Riemannian manifolds of Euclidean signature, a metric is said to be conformally flat if it can be written in the form $ds^2 = e^{\omega(x)}\delta_{\mu\nu}dx^\mu dx^\nu$. Conformal transformations locally preserve the angles but may deform the lengths arbitrarily, so conformal symmetry is typically associated with the absence of an intrinsic length scale. On the conformal compactification (by adding the point at infinity which is necessary for the special conformal transformation to be well-defined) of $\mathbb{R}^{n,0}$ for $n \geq 3$, all conformal transformations are globally well-defined and form a group isomorphic to $SO(n+1,1,\mathbb{R})$. The corresponding local transformations thus form a finite-dimensional Lie algebra isomorphic to $\mathfrak{so}(n+1,1,\mathbb{R})$. In two dimensions, however, the condition of conformal invariance is equivalent to the Cauchy-Riemann equation and any holomorphic function gives rise to an infinitesimal conformal transformation. Use the generators

$$\ell_n = -z^{n+1}\partial_z \ , \quad \bar{\ell}_n = -\bar{z}^{n+1}\partial_{\bar{z}} \tag{3.1}$$

for $n \in \mathbb{Z}$, we see that the local conformal transformations form an infinite-dimensional Lie algebra, which contains two commuting copies of the Witt algebra with commutation relations

$$\mathfrak{Witt}: \quad [\ell_m, \ell_n] = (m-n)\ell_{m+n} \ . \tag{3.2}$$

It is important to emphasise that most of the conformal generators in 2 dimensions are purely local, i.e. they do not generate globally well-defined transformations. Consider, for example, the Riemann sphere $\widehat{\mathbb{C}} = \mathbb{C} \cup \infty$, i.e. the Riemann surface of genus zero. On $\widehat{\mathbb{C}}$, only $\ell_0, \ell_{\pm 1}$ generate global conformal transformations, which form the Möbius group $SO(3,1,\mathbb{R}) \cong PSL(2,\mathbb{C})$.

The quantisation of a 2-dimensional CFT is typically done on $\mathbb{C}$. The theory on the Riemann sphere determines the theory on any other Riemann surface uniquely, but does not guarantee their consistency, as one must also require crossing symmetry and modular invariance of the torus partition function (see below). To see how to quantise on $\mathbb{C}$, we note that $\mathbb{C}$ with origin removed is conformally equivalent to a cylinder $S^1 \times \mathbb{R}$. Denoting by y and t the coordinates for S^1 and the Euclidean time $\mathbb{R}$, the conformal map $z = e^{t+iy}$ maps the cylinder to $\mathbb{C}\backslash\{0\}$ and in particular maps the infinite past to the origin. The usual time ordering on the cylinder becomes radial ordering on the plane, and the associated space of states is built on radial slices.

Anything that resembles a local field $\phi(z, \bar{z})$ is called a field in CFT. If a field depends only on the holomorphic variable z we call it *chiral field* (or *anti-chiral* if it depends only on $\bar{z}$). Upon quantisation, fields become operator-valued distributions that create states in the space of states $\mathcal{H}$, by acting on the vacuum $|0\rangle \in \mathcal{H}$. This is called the *state-field correspondence*, which maps an field ϕ to a state

$$\phi \mapsto |\phi\rangle := \lim_{z,\bar{z}\to 0} \phi(z, \bar{z})|0\rangle \ , \tag{3.3}$$

created at the origin on the plane (or past infinity on the cylinder). A crucial property of a CFT is that the above map is bijective; every state corresponds uniquely to a single local operator, whereas for a typical QFT different fields can produce the same asymptotic state. This can be understood through the fact that under conformal transformation $t \to -\infty$ is mapped to a single local point on $\widehat{\mathbb{C}}$.

The product of two fields inserted at the same point is generically singular. The singularity structure is captured by the so-called *operator product expansion* (OPE)

$$\phi_1(z)\phi_2(z') \sim \sum_{n=0}^{\infty} D_n(z - z')O_n(z') \ , \tag{3.4}$$

where $\sim$ means that we only keep the singular terms. Here $O_n(z)$ are fields of the theory and $D_n(z - z')$ are complex-valued functions with polynomial or logarithmic singularities when $z \to z'$. The non-singular part of $\phi_1(z)\phi_2(z')$ is captured by the *normal-ordered product*, which can be defined as

$$:\!\phi_1(z)\phi_2(z')\!: \ := \phi_1(z)\phi_2(z') - \sum_{n=0}^{\infty} D_n(z - z')O_n(z') \ . \tag{3.5}$$

When there are only polynomial singularities in $D_n(z - z')$ we say that the fields ϕ_1 and ϕ_2 are local with respect to each other, in the sense that there are no branch cuts and contour integrals are well-defined.

The conserved current associated with the continuous conformal symmetry of a 2d CFT is the *stress-energy tensor*, and we denote $T(z) := T_{zz}(z)$ and $\bar{T}(\bar{z}) := T_{\bar{z}\bar{z}}(\bar{z})$. Classically, these are the only non-vanishing components. Upon quantisation on a generic Riemann surface this is broken to $\langle T^a_{\ a}\rangle = -\frac{c}{12}R$ where R is the Ricci scalar.

Since the treatment of the chiral and anti-chiral parts is identical, we will from now on focus on the former. The holomorphicity of the stress-energy tensor $T(z)$ follows from the fact that the associated conserved charges are precisely the generators of infinitesimal holomorphic conformal transformations (3.1). Specifically, we have the mode expansion

$$L_n := \frac{1}{2\pi} \oint T(z) z^{n+1} dz \ \Leftrightarrow \ T(z) = \sum_{n\in\mathbb{Z}} L_n z^{-n-2} \ . \tag{3.6}$$

The modes L_n however, do not generally satisfy the Witt algebra (3.2). This is because the conformal symmetry is typically "softly" broken by quantum effects. The OPE of $T(z)$ with itself,

$$T(z)T(w) \sim \frac{c/2}{(z - w)^4} + \frac{2T(w)}{(z - w)^2} + \frac{\partial T(w)}{z - w} \ , \tag{3.7}$$

is equivalent via the mode expansions to the commutation relations

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}m(m^2-1)\delta_{m+n,0} \ . \tag{3.8}$$

In the above, the real constant c is called *central charge*, and the new algebra is the *Virasoro algebra* $\mathfrak{Vir}$, which is a central extension of $\mathfrak{Witt}$ by the term containing the central charge. Moreover, the two resulting $\mathfrak{Vir}$ copies commute, i.e. $[L_m, \bar{L}_n] = 0$, and there is a central charge $\bar{c}$ associated with the anti-chiral part, which can in principle be different from c. The central charge captures important information of a CFT and gives a measure for the number of degrees of freedom, but there can exist multiple different CFTs with the same central charge. It is related to a "soft" breaking of the conformal symmetry because it indicates that the stress-energy tensor, which generates conformal transformations, transforms anomalously under conformal mappings. For instance, for the transformation $z = e^w, w = t + iy$ from the cylinder to the Riemann sphere, we have

$$T(z) = z^{-2}\left(T_{\text{cyl}}(w) + \frac{c}{24}\right) \ , \tag{3.9}$$

which leads to the following relation between the Hamiltonian $\oint_{\text{time-slice}} dw (T_{\text{cyl}}(w) + \bar{T}_{\text{cyl}}(\bar{w}))$ and $\oint_{\text{radial-slice}} \frac{dz}{z}(T(z) + \bar{T}(\bar{z}))$:

$$H = L_0 + \tilde{L}_0 - \frac{c+\tilde{c}}{24}. \tag{3.10}$$

Similarly, we have the momentum (or *spin*)

$$P = L_0 - \tilde{L}_0 - \frac{c-\tilde{c}}{24}. \tag{3.11}$$

As a result, the eigenvalues of L_0 plays the role of the chiral part of the energy, and the central charge gives rise to non-vanishing ground state energy. The eigenvalue h under L_0 of an eigenstate $|h\rangle \in \mathcal{H}$, i.e. $L_0|h\rangle = h|h\rangle$, is called the *conformal weight* of $|h\rangle$. If, moreover, $L_n|h\rangle = 0$ for all $n > 0$, then $|h\rangle$ is called a *Virasoro primary state* and the corresponding field called a primary field. This terminology also extends to the corresponding fields ϕ_h via the state-field correspondence. A state of the form $L_{-k_1}L_{-k_2}\cdots L_{-k_n}|h\rangle$ $(k_i > 0)$ is called a *Virasoro descendant* of $|h\rangle$. If $|h\rangle$ is a primary state, then along with all of its descendants they form a so-called *Verma module* for $\mathfrak{Vir}$. The primary state $|h\rangle$ is then called the *highest-weight state* of the module, since it has the lowest (somewhat confusingly) conformal weight among all of its descendants.

Since the states organise themselves into Virasoro representations, one can decompose the space of states of a CFT into a direct sum of $\mathfrak{Vir}$ and $\overline{\mathfrak{Vir}}$ modules. In general, focussing on the chiral part, one can have an enlarged symmetry algebra that contains $\mathfrak{Vir}$. This is called the *chiral algebra* of the CFT, and is denoted here by $\mathcal{V}$. We are mainly interested in *rational conformal field theories* (RCFTs), which contain a finite number of such modules; let $\Phi(\mathcal{V})$, $\overline{\Phi}(\overline{\mathcal{V}})$ denote the sets of these (chiral and anti-chiral respectively). The space of states can then be written as

$$\mathcal{H} \ = \bigoplus_{M\in\Phi(\mathcal{V}),\overline{N}\in\overline{\Phi}(\overline{\mathcal{V}})} \mathcal{Z}_{M,\overline{N}}\left(M \otimes \overline{N}\right) \ . \tag{3.12}$$

The states in such RCFTs get organized in $\mathcal{V}$-modules, whose highest-weight states correspond to *chiral primaries*, which are not only Virasoro primaries, but also primaries with respect to $\mathcal{V}$. The chiral descendants are generated by acting with $\mathcal{V}$ on the chiral primaries. This means that if $A(z) \in \mathcal{V}$, then $A(z)M \subset M$ for any $M \in \Phi(\mathcal{V})$.

The subspace $V \subset \mathcal{H}$, corresponding to the chiral algebra $\mathcal{V}$ via the state-field correspondence, always forms an irreducible $\mathcal{V}$-module $V := M_1 \in \Phi(\mathcal{V})$, which contains the vacuum and all states corresponding to the Virasoro primaries generating $\mathcal{V}$, also commonly called *currents*, along with their chiral descendants. Modular invariance requires that the eigenvalues of $L_0 - \overline{L}_0$ are integers, which also means that all states in any $M \in \Phi(\mathcal{V})$ have the same weight up to an integer. Specifically, all states in the vacuum module V should have integer weights. However, by dropping modular invariance as an initial requirement, the chiral algebra can possibly contain currents of half-integer weights (fermionic currents), or any rational weight (parafermions). The price to pay is that these currents have non-local OPEs (in the sense discussed previously), with the corresponding branch cuts leading to the introduction of various sectors (for fermionic currents these would be the Ramond and Neveu-Schwarz sectors). The modular invariant theory can then be constructed by a suitable projection.

The chiral algebras themselves are the central objects in the theory of Vertex Operator Algebras (VOAs), where they are discussed in an axiomatic manner. In the context of moonshine, an important property of a chiral algebra is the finite group part of $\mathrm{Aut}(\mathcal{V})$. The most famous example is the Monster CFT $V^\natural$, which is a VOA with $\mathrm{Aut}(V^\natural) = \mathbb{M}$, the Monster group. Furthermore, $V^\natural$ is an example of a *holomorphic VOA*, i.e. a VOA that has a unique irreducible $\mathcal{V}$-module, namely the space V.

In 2d CFT one is interested in calculating correlation functions of fields, inserted at specific points on a Riemann surface Σ. These can be cast in terms of chiral quantities called *chiral blocks*. Writing $\Sigma = \Sigma_{g,n}$ with genus g and n marked points $p_1, \dots, p_n$, a chiral block is a multilinear map from $M_1 \otimes \cdots \otimes M_n$ to a meromorphic function. This notation means that a field in $M_i \in \Phi(\mathcal{V})$ is inserted at the point p_i. In the case of RCFT, they can often be obtained as solutions to certain differential equations [43–45]. The chiral blocks form representations of the *mapping class group* $\Gamma_{g,n}$, which captures the discrete (and almost always infinite) symmetries of $\Sigma_{g,n}$. It can be defined by the quotient $\Gamma_{g,n} \cong \mathrm{Aut}(\Sigma_{g,n})/\mathrm{Aut}_0(\Sigma_{g,n})$, where $\mathrm{Aut}_0(\Sigma_{g,n})$ is the component of $\mathrm{Aut}(\Sigma_{g,n})$ that is connected to the identity. Hence, $\Gamma_{g,n}$ maps between equivalent Riemann surfaces $\Sigma_{g,n}$, which only differ by a discrete automorphism. As a result, the *moduli space* $\mathcal{M}_{g,n}$, which parametrises the conformally inequivalent Riemann surfaces, has naturally the following quotient form,

$$\mathcal{M}_{g,n} = \mathcal{T}_{g,n}/\Gamma_{g,n} \ , \tag{3.13}$$

where $\mathcal{T}_{g,n}$ is the so-called *Teichmüller space*.

Chiral blocks have in general non-trivial monodromy as functions of the moduli space $\mathcal{M}_{g,n}$ (see for example [40] for more details). Chiral blocks will thus generally be multi-valued functions on $\mathcal{M}_{g,n}$, and in order to make them well-defined one should lift them to $\mathcal{T}_{g,n}$. As a result, they will then carry a representation of the mapping class group $\Gamma_{g,n}$. This is one way to understand the origin of the modular properties of torus blocks, and in particular moonshine modules.

To explain this, let us now focus on the case of $\Sigma_{1,1}$, i.e. tori with a single marked point. As explained in §2.1, a torus can be described up to a scale by $\mathbb{C}/\Lambda_\tau$, where Λ_τ is the lattice in $\mathbb{C}$ generated by the vectors 1 and $\tau \in \mathbb{H}$. An

$SL_2(\mathbb{Z})$ transformation leaves the lattice invariant and as a result the mapping class group $\Gamma_{1,0} = PSL_2(\mathbb{Z})$ is given by the part of $SL_2(\mathbb{Z})$ that acts non-trivially on the Teichmüller space $\mathbb{H}$. As any point is equivalent to any other point on a torus due to its translation symmetries, we also have $\Gamma_{1,0} = \Gamma_{1,1}$ and $\mathcal{M}_{1,0} = \mathcal{M}_{1,1}$.

Chiral blocks on $\Sigma_{1,1}$, when lifted to $\mathcal{T}_{1,1}$, will consequently be functions of the modular parameter τ. For RCFTs, they form a space of finite dimensions, and the dimension is given by the number of irreducible modules in $\Phi(\mathcal{V})$. They admit a natural basis given by the *graded dimensions*, or *characters*, of the irreducible modules $M \in \Phi(\mathcal{V})$

$$ch_M(\tau) = \mathrm{Tr}_M \, q^{L_0 - c/24} \ , \tag{3.14}$$

where $q = e^{2\pi i \tau}$ as before. As discussed previously, the characters furnish a representation of $\Gamma_{1,1} = PSL(2,\mathbb{Z})$, so that the $ch_M(\tau)$ are components of a weakly holomorphic vector-valued modular form for $PSL(2,\mathbb{Z})$. In other words, they mix with each other under the action of the modular group and the way they mix determines their OPE via the Verlinde formula. The modularity of characters of RCFTs is rigorously shown in the context of VOAs by Zhu's Theorem [46].

The *partition function* of a 2d CFT is defined as the 0-point correlation function on the torus, which encodes the spectrum of the theory. In the operator formalism, a torus with modular parameter $\tau = \tau_1 + i\tau_2$ can be obtained from the Riemann sphere by first conformally mapping it to the cylinder $S^1 \times \mathbb{R}$, and then imposing periodic boundary conditions on the Euclidean time direction $\mathbb{R}$. The Hamiltonian and momentum operators H, P then propagate states along both cycles of the torus, so the spectrum is embodied in the trace of the corresponding evolution operator over the space of states,

$$Z(\tau,\bar\tau) := \mathrm{Tr}_{\mathcal{H}} \, e^{2\pi i \tau_1 P - 2\pi \tau_2 H} \ . \tag{3.15}$$

Using (3.10)-(3.11), we can rewrite it as

$$Z(\tau,\bar\tau) = \mathrm{Tr}_{\mathcal{H}} \, q^{L_0 - \frac{c}{24}} \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} \ , \tag{3.16}$$

making it manifest that it is a generating function of the multiplicities of states at given chiral and anti-chiral conformal weights in $\mathcal{H}$. From (3.12) we see that it has the following decomposition in terms of chiral blocks

$$Z(\tau,\bar\tau) = \sum_{M \in \Phi(\mathcal{V}), \overline{N} \in \overline{\Phi}(\overline{\mathcal{V}})} \mathcal{Z}_{M,\overline{N}} \ ch_M(\tau) \overline{ch_{\bar{N}}(\tau)} \ . \tag{3.17}$$

The partition function (3.15) can also be computed using the path integral formalism when a Lagrangian description of the CFT is available. In this language, we have $Z = \int D\phi \ e^{-S[\phi]}$, with the fields having appropriate boundary conditions on the two cycles of the torus. Also from this point of view, it is clear that the partition function should be modular invariant. This invariance imposes severe constraints on the spectrum of 2d CFTs. For instance, modular invariance was used to classify supersymmetric minimal models and further extensions. See [47, 48] and references therein for some of these results. In the context of moonshine, we are mainly interested in the chiral CFT, where the modular properties are not as stringent.

3.2 Orbifolds

A special class of CFTs which is of particular interest for moonshine is the so-called *orbifold CFTs* [49]. The orbifold construction essentially entail "gauging" a discrete symmetry group G of the chiral algebra $\mathcal{V}$. More precisely, it builds a theory whose chiral algebra contains the G-invariant subalgebra $\mathcal{V}^G$ of $\mathcal{V}$, by retaining the G-invariant states of the original theory and introducing new "g-twisted" sector states, for every $g \in G$.

There are two important ways orbifold considerations enter the study of moonshine. First, we will see in §4 explicit constructions of moonshine chiral CFTs obtained by $\mathbb{Z}_2$-orbifolds. Second, the partition functions twined by the finite group symmetries provide the necessary information about the group actions on the moonshine CFT and constitute the modular objects playing a central role in moonshine. Generalising this to the twisted sectors leads to the so-called generalised moonshine, which we will mention in the next part of the lecture.

Orbifold chiral algebra. Here we are mainly interested in orbifolds of chiral RCFTs (rational VOAs). We are interested in automorphisms of the operator algebra. If such an automorphism acts trivially on the operator algebra, i.e. without permuting the modules M_i^e, then it is said to be *inner*. In particular it preserves the chiral algebra of the chiral CFT. Let $\mathcal{V}$ denote the chiral algebra, $G \subseteq \mathrm{Aut}(\mathcal{V})$ a finite symmetry group, and $M_1^e, \ldots, M_n^e$ its irreducible $\mathcal{V}$-modules. Here $e \in G$ denotes the identity element which will later be generalised to arbitrary $g \in G$. In particular, we have $M_1^e = V$, the vacuum module corresponding to $\mathcal{V}$.

Given such a symmetry, the chiral algebra is decomposed in G-representations as

$$\mathcal{V} = \bigoplus_a \rho_a \otimes \mathcal{V}_a \ , \tag{3.18}$$

where the corresponding spaces V_a contain states that transform under the irreducible representations ρ_a of G, and a runs over all of them. The G-invariant subalgebra

$$\mathcal{V}^G := \{\phi \in \mathcal{V} \mid h\phi = \phi \ \ \forall\, h \in G\} \ , \tag{3.19}$$

corresponding to the trivial representation ρ_0 of G, is called the *orbifold chiral algebra* in this setup. Note that while V is irreducible as a $\mathcal{V}$-module, it is generically reducible as a $\mathcal{V}^G$-module, as shown in (3.18). We instead identify the corresponding space V_a, corresponding to $\mathcal{V}_a$, as the irreducible $\mathcal{V}^G$-modules relevant for the orbifold CFT.

An analogous statement holds for the rest of the $\mathcal{V}$-modules, and we have decompositions

$$M_i^e = \bigoplus_a \rho_a \otimes M_{i,a}^e \ . \tag{3.20}$$

An important subtlety is that ρ now runs over all irreducible *projective representations* of G. Projective representations generalise the usual notion of representations introduced in §1.4, by allowing them to respect the group operation up to a phase,

$$\rho(h_1 h_2) = c_e(h_1, h_2)\rho(h_1)\rho(h_2) \ , \tag{3.21}$$

where $c_e(h_1, h_2)$ is a $U(1)$-valued 2-cocycle, representing a class in the group cohomology $H^2(G, U(1))$ of G. This type of behaviour is allowed in CFT because such a phase cancels when the chiral and the anti-chiral contributions are combined and hence is not in conflict with the modular invariance of the final theory. See [50] for a nice survey on projective representations of finite groups. Also note that the G-invariance of the vacuum implies that the vacuum module V carries true representations in the decomposition $V = \bigoplus_a \rho_a \otimes V_a$.

Twinings. For each $h \in G$, acting as an inner automorphism of the operator algebra, we define the *twined characters*

$$ch_i \left(h \underset{e}{\square} ; \tau \right) := \mathrm{Tr}_{M_i^e} \left[h \; q^{L_0 - \frac{c}{24}} \right] \ . \tag{3.22}$$

Note that the the special case $h = e$ simply gives the usual character or *graded-dimensions*, of M_i^e. In terms of the decomposition into irreducible $\mathcal{V}^G$-modules, the twined characters are expressed as

$$ch_i \left(h \underset{e}{\square} ; \tau \right) = \sum_a \chi_a(h) \; ch \left(M_{i,a}^e \right) \ , \tag{3.23}$$

where χ_a are projective characters of G, and $ch \left(M_{i,a}^e \right)$ are the graded dimensions of $M_{i,a}^e$. Using the orthogonality of the projective representations analogous to (1.18) one can obtain the character $ch_i \left(h \underset{e}{\square} ; \tau \right)$ from the 2-cycle and the character of the projective representation ρ_a.

In a similar fashion, we define the twined partition function as

$$Z \left(h \underset{e}{\square} ; \tau, \bar{\tau} \right) := \mathrm{Tr}_{\mathcal{H}} \left[h \; q^{L_0 - \frac{c}{24}} \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} \right] \ . \tag{3.24}$$

In the path integral language, the twined partition function is obtained by imposing h-twisted boundary condition for the fields on the cycle of the torus which is identified with the "temporal" circle, while the boundary condition along the spatial circle remains unchanged, i.e. $\phi(z + \tau) = h \cdot \phi(z)$ and $\phi(z + 1) = \phi(z)$. From this point of view, it is clear that $Z \left(h \underset{e}{\square} ; \tau, \bar{\tau} \right)$ should be invariant under a subgroup of $SL_2(\mathbb{Z})$ that preserves the h-twisted boundary condition ($SL_2(\mathbb{Z})$ transforms the boundary conditions on the two independent cycles of the torus as in (3.27) below).

Twisted sectors. Provided that $\mathcal{V}$ is sufficiently nice, in the sense that it satisfies the so-called C_2-cofiniteness condition (see [40] for the definition), then for any $g \in \mathrm{Inn}(\mathcal{V})$, the inner automorphisms of $\mathcal{V}$, one can define an irreducible *g-twisted $\mathcal{V}$-module* M_i^g for each $i = 1, \cdots, n$ [51]. In an orbifold theory these modules make up the g-twisted sector of the theory. Clearly, G is no longer a symmetry group for these modules; only the centraliser subgroup $C_G(g)$ (cf. §1.1) remains as a symmetry of the g-twisted sector. As a result, for any commuting pair $g, h \in G$, we can analogously define the *twisted-twined characters*

$$ch_i \left(h \underset{g}{\square} ; \tau \right) := \mathrm{Tr}_{M_i^g} \left[h \; q^{L_0 - \frac{c}{24}} \right] \ , \tag{3.25}$$

i.e. the twined characters in the twisted sectors (of which (3.22) is a special case). In the path integral language, they are obtained by additionally imposing g-boundary conditions for the spacial cycle of the torus, i.e. we have $\phi(z + 1) = g \cdot \phi(z)$ as well as $\phi(z + \tau) = h \cdot \phi(z)$. They similarly admit the decomposition

$$M_i^g = \bigoplus_a \; \rho_a \otimes M_{i,a}^g \ , \tag{3.26}$$

where the sum now runs over all irreducible projective representations of $C_G(g)$. Accordingly, an obvious generalisation of (3.23), obtained by replacing e with g and G with $C_G(g)$, also holds for the twisted sectors.

We have already mentioned that the twined partition functions enjoy modular properties. Similarly the characters (3.25) form vector-valued modular forms for some congruence subgroup with certain multiplier systems. This can be understood via the $SL_2(\mathbb{Z})$-action on the boundary conditions: under modular transformations $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z})$ on the torus, the boundary conditions (g,h) on the two cycles change as

$$(g,h) \mapsto \left(h^c g^d, h^a g^b\right) \ . \tag{3.27}$$

As a result, the twisted-twined characters transform as

$$ch_i\left(h\underset{g}{\square}\,;\frac{a\tau+b}{c\tau+d}\right) = \sum_{j=1}^{n} \psi(\gamma,g,h)_{ij}\ ch_i\left(h^a g^b\underset{h^c g^d}{\square}\,;\tau\right) \ , \tag{3.28}$$

where $\psi(\gamma,g,h)$ is an $n \times n$ matrix with scalar entries. The special case of *holomorphic VOAs* , i.e. those that contain only a single irreducible (untwisted) $\mathcal{V}$-module $\mathcal{H}$, is the easiest to describe. In this case, the chiral partition function coincides with the character of the chiral algebra and (3.28) becomes [52]

$$\begin{aligned} Z\left(h\underset{g}{\square}\,;\tau+1\right) &= c_g(g,h) Z\left(gh\underset{g}{\square}\,;\tau\right) \ , \\ Z\left(h\underset{g}{\square}\,;-\frac{1}{\tau}\right) &= \overline{c_h\,(g,g^{-1})} Z\left(g^{-1}\underset{h}{\square}\,;\tau\right) \ , \end{aligned} \tag{3.29}$$

where now the phases are given by a 2-cocycle representing a class in $H^2(C_G(g),U(1))$ as in (3.21). Moreover, all the phases for all g should descend from a 3-cocycle representing a class in $H^3(G,U(1))$ [52,53].

In a non-chiral CFT, the spectrum consists of the G-invariant parts of all the twisted sectors, leading to the following expression for the partition function

$$Z(\tau,\overline{\tau}) = \frac{1}{|G|} \sum_{gh=hg} Z(g,h)\epsilon(g,h) \tag{3.30}$$

where $\epsilon(g,h)$ is a phase called the *discrete torsion*, which is just 1 in the simplest cases of orbifold constructions. As usual, the above partition function is modular invariant in a consistent orbifold CFT.

3.3 Elliptic genus

In the previous subsections we have discussed conformal theories in general. In the context of string theory and in this lecture, we often encounter 2d CFTs with supersymmetries. In this subsection, we will start with introducing some necessary background on superconformal algebras and their representations, and in particular explain what an elliptic genus is, first from a physics point of view and then from a geometric point of view.

With supersymmetries, the presence of fermions leads to many new features, stemming from the fact that there is now an extra $\mathbb{Z}_2$ grading on the Hilbert space: $V = V_0 \oplus V_1$. (In the context of moonshine, this leads to supermodules of finite groups, cf. (1.20).) For instance, in the context of type II superstrings compactified on Calabi-Yau manifolds, the relevant "internal" CFT is a non-linear sigma model with $\mathcal{N} = 2$ supersymmetry. The Calabi-Yau structure of the target space guarantees that the theory has the $\mathcal{N} = 2$ extension of Virasoro symmetry, given by the so-called $\mathcal{N} = 2$ superconformal algebra (SCA). In particular, superstrings on $K3$ manifolds and the corresponding elliptic genus will play an important role in §8.

The terminology "$\mathcal{N} = 2$" refers to the fact that we include 2 fermionic currents in the algebra on top of the bosonic energy-momentum tensor $T(z)$. Furthermore, there's now an extra automorphism, called the R-symmetry, that rotates different fermionic currents onto each other.

We denote the two fermionic currents by $G_+(z)$ and $G_-(z)$ and the $U(1)$ R-symmetry current rotating the two by $J(z)$. The algebra reads

$$\begin{aligned}
[L_m, L_n] &= (m-n)L_{m+n} + \frac{c}{12}m(m^2-1)\,\delta_{m+n,0} \\
[J_m, J_n] &= \frac{c}{3}m\,\delta_{m+n,0} \\
[L_n, J_m] &= -m\,J_{m+n} \\
[L_n, G_r^\pm] &= (\frac{n}{2}-r)\,G_{r+n}^\pm \\
[J_n, G_r^\pm] &= \pm G_{r+n}^\pm \\
\{G_r^+, G_s^-\} &= 2L_{r+s} + (r-s)J_{r+s} + \frac{c}{3}(r^2 - \frac{1}{4})\,\delta_{r+s,0}\ ,
\end{aligned} \tag{3.31}$$

and all other (anti-)commutators are zero. As before we have two possible boundary conditions for the fermions

$$\begin{cases} 2r = 0 \bmod 2 & \text{for R sector} \\ \\ 2r = 1 \bmod 2 & \text{for NS sector}\ . \end{cases} \tag{3.32}$$

Two comments about this algebra are in order here. First, we have now two generators, L_0 and J_0, of the Cartan subalgebra. As a result, the representations will now be graded by two "quantum numbers", given by the eigenvalues of the L_0 and J_0 of the highest weight vector. The second new feature is that there is a non-trivial inner automorphism of the algebra, which means that the algebra remains the same under the following redefinition

$$\mathbf{SF}_\eta :\ \begin{aligned} L_n &\mapsto L_n + \eta J_n + m\,\eta^2\,\delta_{n,0} \\ J_n &\mapsto J_n + 2m\,\eta\,\delta_{n,0} \\ G_r^\pm &\mapsto G_{r\pm\eta}^\pm \end{aligned} \tag{3.33}$$

with $\eta \in \mathbb{Z}$. This automorphism is called *spectral flow*, and in the above we have written $m := c/6$. If instead we choose $\eta \in \mathbb{Z} + 1/2$ we exchange the Ramond and the Neveu-Schwarz algebra. Note that the only operator (up to trivial rescaling and the addition of central terms, of course) invariant under such a transformation is $4mL_0 - J_0^2$. Recall also that NS sector states give spacetime fermions and Ramond sector states give spacetime bosons. Hence the spectral flow operator has an intimate relation to spacetime supersymmetries.

Ramond ground states and the Witten index. In what follows we will focus on the Ramond algebra and define the Ramond ground states of $\mathcal{N} = 2$ SCFT. As usual, we require the ground states to be annihilated by all the positive modes:

$$L_n|\phi\rangle = J_m|\phi\rangle = G_r^\pm|\phi\rangle = 0 \quad \text{for all} \quad m, n, r > 0\ .$$

Moreover, they have to annihilated by the zero modes of the fermionic currents

$$G_0^{\pm}|\phi\rangle = 0\ .$$

This condition fixes their L_0-eigenvalue to be

$$\frac{1}{2}\{G_0^+, G_0^-\}|\phi\rangle = \Big(L_0 - \frac{c}{24}\Big)\,|\phi\rangle = 0\ .$$

Let's ignore the right-moving part of the spectrum for a moment and consider a chiral Hilbert space V. We define its Witten index as

$$\mathrm{WI}(\tau, V) = \mathrm{Tr}_V\left((-1)^{J_0} q^{L_0 - \frac{c}{24}}\right)\ .$$

If a state $|\psi\rangle$ is not annihilated by G_0^+, then the states $|\psi\rangle$ and $G_0^+|\psi\rangle$ together contribute 0 to $\mathrm{WI}(\tau, V)$ since $[L_0, G_0^+] = 0$ while $[J_0, G_0^+] = G_0^+$. The same argument holds for G_0^- and we conclude that only Ramond ground states can contribute to the Witten index. As a result, the Witten index WI : $\{\mathcal{N} = 2 \text{ SCFT}\} \to \mathbb{Z}$ is independent of τ and counts (with signs) the number of Ramond ground states in V.

Notice moreover that the Witten index for $\mathcal{N} = 2$ SCFT acquires an interpretation as computing the graded dimension of the cohomology of the G_0^+ operator, satisfying $(G_0^+)^2 = 0$. For $\{G_0^+, (G_0^+)^\dagger\} = \{G_0^+, G_0^-\} = L_0 - \frac{c}{24}$, the Ramond ground states have the interpretation as the harmonic representative in the cohomology. This fact underlies the rigidity property of the Witten index and the elliptic genus which we will define now.

The same analysis can be trivially extended when one has a non-chiral theory with both left- and right-moving degrees of freedom: the Witten index

$$\mathrm{WI}(\tau, \bar\tau, V) = \mathrm{Tr}_V\left((-1)^{\tilde J_0 + J_0} \bar q^{\tilde L_0 - \frac{\tilde c}{24}} q^{L_0 - \frac{c}{24}}\right)$$

counts states that are Ramond ground states for both the left- and the right-moving copy of $\mathcal{N} = 2$ SCA.

The $\mathcal{N} = 2$ elliptic genus. It is fine to be able to compute the graded dimension of a cohomology, but we can go further and compute more interesting properties of this vector space. For instance, we have learned that the representations of $\mathcal{N} = 2$ SCA are labelled by two quantum numbers corresponding to the Cartan generators L_0 and J_0. It will hence be natural to consider the following quantity which computes the dimension of $\tilde G_0^+$ cohomology graded by the left-moving quantum numbers L_0, J_0.

The elliptic genus of a $\mathcal{N} = (2, 2)$ SCFT is defined as the following Hilbert space trace

$$\mathbf{EG}(\tau, z) = \mathrm{Tr}_{\mathcal{H}_{\mathrm{RR}}}\left((-1)^{J_0 + \bar J_0} y^{J_0} q^{L_0 - c/24} \bar q^{\bar L_0 - c/24}\right)\ , \quad y = e^{2\pi i z}\ , \tag{3.34}$$

where $\mathcal{H}_{\mathrm{RR}}$ denotes the Hilbert space of states that are in the Ramond sector of the $\mathcal{N} = 2$ SCA both for the left- and right-moving copy of the algebra. From the same argument as that for the Witten index, this quantity will be independent on $\bar q$ and will hence be holomorphic as a function of both τ and z.

Note that the elliptic genus can be seen as something between the partition function and the Witten index. While the former counts all states and the latter counts only RR ground states, the elliptic genus counts states that are Ramond ground state on one side and unconstrained on the other side. It contains a lot more information but still has the rigidity property of the Witten index which makes it possible to compute for many SCFTs, and as such it offers a good balance between information content and computability.

When the theory has a finite group symmetry G which commutes with the superconformal symmetries, one can define the ellpitic genus twined by $g \in G$ as

$$\mathbf{EG}_g(\tau, z) = \mathrm{Tr}_{\mathcal{H}_{\mathrm{RR}}}\left(g\, (-1)^{J_0+\bar{J}_0} y^{J_0} q^{L_0 - c/24} \bar{q}^{\bar{L}_0 - c/24} \right). \tag{3.35}$$

These objects will play an important role in the discussions in Part II and III.

Modular properties. As in the case of partition functions (cf. §3.1), a path integral interpretation of the elliptic genus suggests it has nice transformation property under the torus mapping class group. Moreover, the inner automorphism of the algebra (the spectral flow symmetry) implies that the graded dimension of a L_0-, J_0- eigenspace should only depends on its eigenvalue under the eigenvalue of the combined operator $4mL_0 - J_0^2$ and the charge of J_0 mod $2m$ where $m = c/6$. Hence, the Fourier expansion of the elliptic genus should take the form

$$\mathbf{EG}(\tau, z) = \sum_{n,\ell} q^n y^\ell \, c(4mn - \ell^2, \ell) \ .$$

where $c(D, \ell)$ only depends on D and ℓ mod $2m$ (cf. (2.26)). From these facts one can deduce that the elliptic genus of an $\mathcal{N} = (2, 2)$ SCFT with central charge $c = 6m$ is a weak Jacobi form of weight zero and index m. Similarly, following the same argument and that in §3.2, the twined elliptic genera are also weak Jacobi form of weight zero and the same index, but with the modular group $SL_2(\mathbb{Z})$ in (2.25) replaced by a certain subgroup which depends on the twining symmetry g.

The geometric elliptic genus. For a compact complex manifold M with $\dim_{\mathcal{C}} M = d_0$, we can define its elliptic genus as the character-valued Euler characteristic of the infinite-dimensional formal vector bundle [54–58]

$$\mathbf{E}_{q,y} = y^{d/2} {\textstyle\bigwedge}_{-y^{-1}} T_M^* \bigotimes_{n\geq 1} {\textstyle\bigwedge}_{-y^{-1}q^n} T_M^* \bigotimes_{n \geq 1} {\textstyle\bigwedge}_{-yq^n} T_M \bigotimes_{n\geq 0} S_{q^n}(T_M \oplus T_M^*),$$

where T_M and T_M^* are the holomorphic tangent bundle and its dual, and we adopt the notation

$${\textstyle\bigwedge}_q V = 1 + qV + q^2 {\textstyle\bigwedge}^2 V + \dots, \quad \text{and} \quad S_q V = 1 + qV + q^2 S^2 V \dots,$$

with $S^k V$ denoting the k-th symmetric power of V. In other words, we have

$$\mathbf{EG}(\tau, z; M) = \int_M ch(\mathbf{E}_{q,y}) \mathrm{Td}(M). \tag{3.36}$$

From the above definition we see that this “stringy” topological quantity reduces to the familiar ones: the Euler number, the signature, and the $\hat{A}$ genus of M, when we specialise z to $z = 0, \tau/2, (\tau + 1)/2$, respectively.

When M has vanishing first Chern class, in particular when M is a Calabi–Yau manifold, its elliptic genus $\mathbf{EG}(\tau, z; M)$ can be shown to be a weak Jacobi form of weight zero and index $d_0/2$ [58]. Note that the supersymmetric sigma model on a Calabi–Yau manifold flows to a superconformal SCFT in the infrared. The elliptic genus of this $\mathcal{N} = (2, 2)$ SCFT, defined as in (3.34), then coincides with the geometric elliptic genus defined in (3.36) of the Calabi–Yau manifold.

Examples: $K3$ and T^4. There are two topologically distinct Calabi-Yau two-folds: $K3$ and T^4. We expect their elliptic genus to be weight zero weak Jacobi forms with index 1. Coincidentally, the space of such a form is one-dimensional and is spanned by $\phi_{0,1}(\tau, z)$ (cf. (2.31)), and hence we only need one topological invariant of the Calabi-Yau two-folds to fix the whole elliptic genus. From

$$\mathbf{EG}(\tau, z = 0; T^4) = \chi(T^4) = 0 \quad , \quad \mathbf{EG}(\tau, z = 0; K3) = \chi(K3) = 24$$

and

$$\phi_{0,1}(\tau, z = 0) = 12$$

we obtain

$$\mathbf{EG}(\tau, z; T^4) = 0 \quad , \quad \mathcal{Z}(\tau, z; K3) = 2\phi_{0,1}(\tau, z) \ .$$

This clearly demonstrates the power of modularity in gaining extremely non-trivial information about the spectrum of $\mathcal{N} = (2, 2)$ SCFT.

Remark. The argument for the holomorphicity of the elliptic genus fails in an interesting way for theories whose spectrum has a continuous part. Due to the possible spectral asymmetry (i.e. non-perfect pairing between bosonic and fermionic states), the elliptic genus, when defined as a trace/integral over the full Hilbert space with continuous spectrum included, of such a theory could develop a non-trivial $\bar{q}$-dependence. For such an object the usual path-integral intuition still holds and the resulting non-holomorphic function transforms as a Jacobi form. Restricting to the discrete part of the spectrum, the analogous trace will be holomorphic but will no longer be modular. In particular, it will be a mock Jacobi form. As a result, in this context the holomorphic part of the elliptic genus is a well-defined notion both from a physical and mathematical point of view. From the physics perspective, the holomorphic part corresponds to the contribution from the discrete part of the spectrum [24, 27, 30, 59]. From the mathematical point of view, the holomorphic part corresponds to the holomorphic part of the harmonic Maass form [60]. We will encounter such a situation in §8.2.

Part II

Moonshine

In this part we describe classical and recent cases of moonshine connections, focussing on the mathematical statements and postponing the physics till the next part. We organise the different cases in terms of the weights of the modular objects involved, and we will see that in different weights the moonshine relations have features that are different in interesting ways.

4 Moonshine at weight zero

Here we review the two moonshine connections, monstrous and Conway moonshine, that occur at weight zero. They are the moonshine cases that are best understood at the moment, in terms of the specification of the modular objects, the origin of the symmetries, and their physical context.

4.1 Monstrous moonshine

Monstrous moonshine is arguably one of the most fascinating chapters of mathematics in the last century, where finite groups and modular objects were first noticed to be related via physical structures. As the theory of moonshine further develops, we believe that monstrous moonshine will remain the most distinguished example of moonshine phenomenon from various points of view. In this section we briefly describe the features of monstrous moonshine, and we refer to [40, 61, 62] and references therein for other excellent reviews of this beautiful story, in particular the historical aspects of it.

The term *monstrous moonshine*, coined in [63], refers to the unexpected connection between the representation theory of the Monster group $\mathbb{M}$ and the modular form

$$J(\tau) = \sum_{n\geq -1} a_n\, q^n = q^{-1} + 196884q + 21493760q^2 + 864299970q^3 + \cdots \ , \qquad (4.1)$$

which we encountered in (2.5). The development of monstrous moonshine was initiated with the key observation, due to McKay, that the coefficient 196884 in the q-expansion of J can be decomposed as $196884 = 1 + 196883$, where the summands are the dimensions of the two smallest irreducible represenations of $\mathbb{M}$. Similar decompositions were observed for the next few coefficients by Thompson in [64]:

$$\begin{aligned} 1 &= 1 \\ 196884 &= 196883 + 1 \\ 21493760 &= 21296876 + 196883 + 1 \\ 864299970 &= 842609326 + 21296876 + 2\cdot 196883 + 2\cdot 1 \\ &\cdots \end{aligned} \qquad (4.2)$$

where 1, 196883, 21296876, and 842609326 are dimensions of certain irreducible representations of $\mathbb{M}$. The observation led to the conjecture of the existence of an infinite-dimensional $\mathbb{Z}$-graded Monster module,

$$V = \bigoplus_{n\geq -1} V_n \ , \qquad (4.3)$$

such that $\dim V_n = a_n$ for all $n \geq -1$. In other words, J acquires the interpretation as the graded dimension of V

$$J(\tau) = \sum_{n\geq -1} \dim V_n q^n. \tag{4.4}$$

Notice that V_0 is empty, corresponding to the vanishing constant coefficient of J.

The conjecture. This conjecture as stated above is not interesting since one could take each V_n to contain $c(n)$ copies of the trivial representation of $\mathbb{M}$ to make (4.4) true, given the fact that all a_n are non-negative integers. To access the information on the $\mathbb{M}$-action, Thompson also proposed in [65] to look at the graded characters of V, the so-called *McKay-Thompson series* defined by

$$T_g(\tau) \coloneqq \sum_{n\geq -1} \mathrm{Tr}_{V_n}(g) q^n \ , \tag{4.5}$$

for each element $g \in \mathbb{M}$ (with $T_e = J$). Note that the q-series $T_g(\tau)$ must also have vanishing constant term. As is clear from the definition, the T_g are class functions, i.e. $T_g = T_{hgh^{-1}}$. As a result, there are at most 194 distinct T_g as $\mathbb{M}$ has 194 conjugacy classes. In fact, it turns out that T_g only gives rise to 171 distinct functions. The main point of monstrous moonshine lies in the fact that these graded trace functions also exhibit modular properties and are moreover the unique Hauptmoduls with no constant terms (cf. §2.1), as stated in the following astonishing conjecture made by Conway and Norton [63]:

Conjecture 4.1. (Monstrous Moonshine Conjecture)
For each $g \in \mathbb{M}$ the McKay-Thompson series T_g coincides the unique Hauptmodul J_{Γ_g} with expansion $q^{-1} + O(q)$ near $\tau \to i\infty$, for some genus zero subgroup $\Gamma_g \leq SL_2(\mathbb{R})$. Furthermore, each Γ_g contains $\Gamma_0(N)$ as a normal subgroup, for some N dividing the quantity $|g| \gcd(24, |g|)$.

Given the importance of this conjecture, we will pause to make a few comments. Note that Γ_g is often not a subgroup of $SL_2(\mathbb{Z})$; only for some g we have $\Gamma_g = \Gamma_0(N)$ (cf. (2.8)), for some N satisfying the conditions mentioned above. In general, Γ_g is a normaliser of $\Gamma_0(N)$ in $SL_2(\mathbb{R})$, which in general involves the so-called Atkin-Lehner involutions. For later purpose we will be particular interested in the groups of the form

$$\Gamma^{N+K} \coloneqq \left\{ \frac{1}{\sqrt{n}} \begin{pmatrix} an & b \\ cN & dn \end{pmatrix} \mid adn - bcN/n = 1,\ n \in K \right\}, \tag{4.6}$$

where $K < \mathrm{Ex}_N$ is a subgroup of the group of exact divisors of N. We say that e is an exact divisor of N if $e|N$ and $(f, \frac{N}{f}) = 1$, and they form a group with multiplication $f * f' = \frac{ff'}{(f,f')^2}$. An especially simple case is when N is a prime number p, and the full normaliser (corresponding to $K = \{1, p\}$) is given by

$$\Gamma_0(p)+ \coloneqq \left\langle \Gamma_0(p), \frac{1}{\sqrt{p}} \begin{pmatrix} 0 & -1 \\ p & 0 \end{pmatrix} \right\rangle . \tag{4.7}$$

A harbinger of monstrous moonshine, predating the observation by McKay, is the following observation made by Ogg [66]. He noted that $\Gamma_0(p)+$ defines a genus zero quotient on the upper-half plane if and only if

$$p \in \{2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 47, 59, 71\}, \tag{4.8}$$

and this is precisely the set of primes dividing the order of the Monster group, and subsequently offered a bottle of Jack Daniel's to anyone who can explain the coincidence [66]. Monstrous moonshine sheds light on this mysterious coincidence through the fact that the Hauptmoduls of all the genus zero $\Gamma_0(p)+$ feature in moonshine as the McKay-Thompson series T_g for a $g \in \mathbb{M}$ with order p. In the case $\Gamma_g \not\subset SL_2(\mathbb{Z})$ the modularity of CFT does not help to explain the appearance of modularity for Γ_g, since in CFT modularity arises from the mapping class group of the torus (cf. §3). The crucial genus zero property of monstrous moonshine received a useful paraphrasing [67] as the property that these Hauptmoduls can be obtained as a *Rademacher sum*, a regularised sum over the images of the polar term (in this case q^{-1}) under the action of the appropriate subgroup of $SL_2(\mathbb{R})$ (in this case Γ_g). This *Rademacher summability* property subsequently played a key role in the discovery of umbral moonshine (cf. §5.2). Recently, the genus zero property is explained by noting that Γ_g plays the role of the stringy symmetry group in the string realisation of the Monster theory and by requiring a physical analyticity condition on the supersymmetric index of the theory. See §7 for more details.

The moonshine module. This conjecture was verified numerically by Atkin, Fong and Smith (cf. [68, 69]), following the idea of Thompson (see [40] for references). To be more specific, they showed that, for each $n \geq -1$, the q^n-coefficient of the Hauptmoduls specified in [63] coincide with the characters of a certain virtual representation of $\mathbb{M}$. A constructive verification was later obtained by Frenkel, Lepowsky and Meurman [70, 71], with the explicit construction of a Monster module $V = V^\natural$. This module has the structure of holomorphic VOA, i.e. a VOA with a single irreducible $V^\natural$-module, namely itself.

The starting point for constructing $V^\natural$ is 24 chiral bosons $X^i(z)$, compactified on the 24 dimensional torus $\mathbb{R}^{24}/\Lambda$ defined by the Leech lattice Λ. This results into a VOA $V(\Lambda)$ with central charge $c = 24$, leading to a partition function whose q-expansion starts with $Z_{V(\Lambda)}(\tau) = q^{-1} + \ldots$. This, together with the modular invariance, fixes the function to be the same as $J(\tau)$ up to an additive constant. At the same time, we know what this constant has to be since the Leech lattice has no root vectors and hence $\Theta_\Lambda(\tau) = \sum_{v\in\Lambda} q^{\langle v,v\rangle/2} = 1 + O(q^2)$, leading to

$$Z_{V(\Lambda)}(\tau) = \frac{\Theta_\Lambda(\tau)}{\eta^{24}(\tau)} = J(\tau) + 24 \ . \tag{4.9}$$

In other words, thanks to the root-free property of the Leech lattice the lattice vertex operators of the form $e^{ik\cdot\Phi}$ all have weight larger than one, and the only remaining weight one primaries are the 24 fields ∂X^i.

In order to have an exact matching with J we would like to remove these primaries, which can be achieved by a simple $\mathbb{Z}_2$ orbifold of $V(\Lambda)$, acting as $X^i \to -X^i$, which corresponds to the $\{\mathrm{id}, -\mathrm{id}\} \cong \mathbb{Z}_2$ symmetry of Λ, contained in $\mathrm{Aut}(\Lambda) \cong Co_0$. Indeed, one can easily compute the partition function of the orbifolded theory explicitly as follows. Note that the $\mathbb{Z}_2$-twined partition function of 24 chiral bosons is given by

$$Z\left(-\underset{+}{\square}\,;\tau\right) = \frac{1}{q\prod_{n>0}(1+q^n)^{24}} = \left(\frac{2\eta(\tau)}{\theta_2(\tau)}\right)^{12} . \tag{4.10}$$

The orbifold entails that $V^\natural$ is the direct sum of the $\mathbb{Z}_2$-invariant projections of the untwisted and twisted sectors respectively (cf. (3.30)). From (3.29) and (2.13) we have

$$\begin{aligned} Z_{V^\natural}(\tau) &= \frac{1}{2}\left(J(\tau) + 24 + \left(\frac{2\eta(\tau)}{\theta_2(\tau)}\right)^{12} - \left(\frac{2\eta(\tau)}{\theta_3(\tau)}\right)^{12} + \left(\frac{2\eta(\tau)}{\theta_4(\tau)}\right)^{12}\right) \\ &= J(\tau). \end{aligned} \tag{4.11}$$

It remains to see that $\mathrm{Aut}(V^\natural)$ is the Monster. Note that $\mathrm{Aut}V(\Lambda)$ has a continuous piece T which is a 24-dimensional torus corresponding to the translation symmetry of the chiral bosons and to the 24 weight-one primary fields ∂X^i. The total symmetry is captured by the (non-split) short exact sequence

$$1 \to T \to \mathrm{AutV}(\Lambda) \to Co_0 \to 1 \ . \tag{4.12}$$

The $\mathbb{Z}_2$-orbifold breaks the automorphism group to its discrete part $2^{24}.\,Co_0$, which preserves the decomposition $V^\natural = V^\natural_+ \oplus V^\natural_-$ and is suggestively similar to a certain maximal subgroup $2^{1+24}.\,Co_1$ of $\mathbb{M}$. It is clear from the contribution to the weight two (and similarly for weight three, four, ...) states in $V^\natural$ from $V^\natural_+$ and $V^\natural_-$ that the Monster must mix them and hence cannot preserve the (un)twisted sector individually. Note that the 196884-dimensionl space of weight two states of $V^\natural$ has the structure of a commutative and non-associative algebra (as is true for any VOA), and can be shown to be precisely the *Griess algebra* constructed in 1980 and used to construct the Monster group itself [72]. From this and the VOA structure of $V^\natural$ one can show that $\mathrm{Aut}(V^\natural)$ is indeed the Monster, and can be obtained by adjoining a certain order two symmetry mixing $V^\natural_\pm$ to the discrete part of $\mathrm{Aut}(V(\Lambda))$.

The proof of monstrous moonshine. To prove that the $V^\natural$ constructed by Frenkel, Lepowsky and Meurman indeed "does the job", one needs to show that

$$T_g^{V^\natural}(\tau) := \mathrm{Tr}_{V^\natural}\, g\, q^{L_0 - c/24} \tag{4.13}$$

coincides with the corresponding Hauptmodul J_{Γ_g} specified in [63]. It was known that the coefficients of Hauptmoduls satisfy certain recursive formulas and one can determine all coefficients from just a handful of them. In the simplest case the recursive formulas are encoded in the remarkable identity

$$p^{-1} \prod_{\substack{m>0 \\ n\in\mathbb{Z}}} (1 - p^m q^n)^{a_{mn}} = J(\rho) - J(\tau) \ , \tag{4.14}$$

independently discovered by Zagier, Borcherds and others. Here $p = e^{2\pi i \rho}$, and a_i denotes the q^i coefficients in the q-expansion of J (cf. (4.1)). This identity results in infinitely many relations between a_i, which enables one to completely fix all the coefficients from just a_1, a_2, a_3, a_5. Clearly, the proof can be achieved if one can show the existence of the same type of identities among the coefficients of $T_g^{V^\natural}(\tau)$, and just explicitly compare the handful of coefficients that are necessary to fix the whole functions on both sides.

This is precisely what Borcherds did, and he obtained the replication formulas by introducing the notion of a *generalised Kac-Moody algebra*, which can be viewed as a generalisation of Kac–Moody algebras that allows for imaginary simple roots. Subsequently, he constructed a generalised Kac-Moody algebra (also called "Borcherds-Kac-Moody algebra") $\mathfrak{m}$, called the Monster Lie algebra. Roughly speaking, the construction was achieved by studying the cohomology of a BRST-like operator, which acts on $V^\natural \times \Gamma^{1,1}$, where $\Gamma^{1,1}$ is the unique unimodular lattice of signature $(1,1)$. This construction has a natural interpretation in string theory of considering second quantised strings in the background of $V^\natural$. See §7 for more details.

Borcherds managed to derive the replication formulas (4.14) as the *denominator identities* of the Monster Lie algebra $\mathfrak{m}$ that he attached to $V^\natural$. As in usual Kac–Moody algebras, the denominator identity results from applying the Weyl-Kac character formula of a Lie algebra to the trivial representation, and in this case relates an infinite sum to an infinite product, precisely the structure we see in (4.14). Moreover, by considering the $\mathbb{M}$-action on $V^\natural$ one can also obtain from $\mathfrak{m}$ the analogous identity

$$p^{-1}\exp\left[-\sum_{k>0}\sum_{\substack{m>0\\ n\in\mathbb{Z}}} a^{g^k}_{mn}\frac{p^{mk}q^{nk}}{k}\right] = J_{\Gamma_g}(z) - J_{\Gamma_g}(\tau)\ , \tag{4.15}$$

satisfied by the other Hauptmoduls, where a^g_i are the q-expansion coefficients of J_{Γ_g}. Combining the above components then proves the validity of $V^\natural$ as the module of monstrous moonshine.

Generalised monstrous moonshine. In [73] Norton proposed a generalisation of monstrous moonshine under the name of *generalised monstrous moonshine*. He suggested that there is a rule to assign to each element $g \in \mathbb{M}$ a graded projective representation $V(g) = \bigoplus_{n\in\mathbb{Q}} V(g)_n$ of the centralizer group $C_{\mathbb{M}}(g)$, and to each pair (g,h) of commuting elements of $\mathbb{M}$ a holomorphic function $T_{(g,h)}$ on the upper half-plane $\mathbb{H}$, which satisfies the following conditions:

(i) $T_{(g^ah^c,g^bh^d)}(\tau) = \gamma\ T_{(g,h)}\left(\frac{a\tau+b}{c\tau+d}\right)$ with $\begin{pmatrix} a & b\\ c & d\end{pmatrix} \in SL_2(\mathbb{Z})$ and γ being a 24th root of unity.

(ii) $T_{(g,h)}(\tau) = T_{(k^{-1}gk,k^{-1}hk)}(\tau)$ with $k \in \mathbb{M}$.

(iii) There is a lift $\tilde{h}$ of h to a linear transformation on $V(g)$ such that

$$T_{(g,h)}(\tau) = \sum_{n\in\mathbb{Q}} \mathrm{Tr}_{V(g)_n}\left(\tilde{h}\ q^{n-1}\right)\ . \tag{4.16}$$

(iv) $T_{(g,h)}(\tau)$ is either a constant or a Hauptmodul for some genus-zero congruence subgroup of $SL_2(\mathbb{Z})$.

(v) $T_{(e,h)}(\tau)$ coincide with $T_h(\tau)$, the McKay-Thompson series attached to $h \in \mathbb{M}$ by monstrous moonshine.

As we can see from the discussion in §3.2, all of these properties, apart from (iv), can be understood in the framework of holomorpic orbifolds [74], applied to $V^\natural$. In particular, the function $T_{(g,h)}$ can be thought of the h-twined character of the twisted module $V^\natural_g$. The proof of generalised monstrous moonshine was carried out recently in [75], where a generalised Kac–Moody algeba $\mathfrak{m}_g$, generalising the monster Lie algebra $\mathfrak{m}$, is constructed for all $g \in \mathbb{M}$.

4.2 Conway moonshine

Conway moonshine establishes the relation between Co_0, related to Conway's sporadic group Co_1 by $Co_1 \cong \mathrm{Co}_0/\{\pm\mathrm{Id}\}$, and Hauptmoduls of certain genus zero subgroups of $SL_2(\mathbb{R})$.

Recall from §1.3 that Co_0 is isomaprhic to the automorphism group of the Leech lattice Λ. In this context, hints of Conway moonshine had already appeared in the original montrous moonshine paper [63], where the authors assigned genus zero groups $\Gamma_g < SL_2(\mathbb{R})$ to elements $g \in \mathrm{Co}_0$: let $\{\lambda_i, \lambda_i^{-1}\}_{i=1}^{12}$ be the 24 eigenvalues of the natural g-action on the Leech lattice $\Lambda \otimes_{\mathbb{Z}} \mathbb{C}$ (embedded in a complex vector space), then Γ_g is given by the invariance groups of the holomorphic function

$$t_g(\tau) := q^{-1} \prod_{n>0} \prod_{i=1}^{12} \left(1 - \lambda_i q^{2n-1}\right)\left(1 - \lambda_i^{-1} q^{2n-1}\right) = q^{-1} - \chi_g + \mathcal{O}(q) \ . \tag{4.17}$$

Note that $\chi_g = \sum_i (\lambda_i + \lambda_i^{-1})$ is generically non-vanishing, and t_g has non-zero constant terms unlike the monstrous moonshine functions discussed in the previous subsection.

Conway moonshine, on the other hand, introduces a Conway module $V^{s\natural}$ whose McKay–Thompson series coincide with Hauptmoduls with vanishing constant terms. It was developed in [76, 77] (see also [78], [79] and [80] for nice summaries of the construction). The Conway module $V^{s\natural}$ is the unique, up to isomorphisms, super-VOA (SVOA) with $c_{V^{s\natural}} = 12$ and $N = 1$ superconformal structure, characterized by the absence of states with weight 1/2. It can be constructed as a $\mathbb{Z}_2$ orbifold of the theory with eight bosons on the E_8 torus together with their fermionic superpartners. Alternatively, it can be constructed as a $\mathbb{Z}_2$ orbifold, acting as $k_a \to -k_a$, of 24 free chiral fermions k_a, $a = 1, 2, \dots, 24$. This is to be compared with the monstrous moonshine module $V^\natural$, where the corresponding Monster module $V^\natural$ is built as a $\mathbb{Z}_2$ orbifold of the Leech lattice VOA (24 chiral bosons compactified on $\mathbb{R}^{24}/\Lambda$), resulting in theory with $c_{V^\natural} = 24$ and no states of weight 1. It turns out that $V^{s\natural}$ has an interesting relation to stringy symmetries of K3 surfaces (see §8.3). In what follows we will give more details on the Conway module $V^{s\natural}$.

Consider 24 real chiral fermions k_a and the corresponding complex fermions

$$\psi_j^{\pm} = \frac{1}{\sqrt{2}} \left(k_{2j-1} \pm i k_{2j}\right) \ , \quad j = 1, \dots, 12 \ , \tag{4.18}$$

with the following non-vanishing OPEs and stress-energy tensor

$$\psi_i^{\pm}(z)\psi_j^{\mp}(w) \sim \frac{\delta_{ij}}{z-w} \ , \qquad L = -\frac{1}{2}\sum_{i=1}^{12} {:}\psi_i^+ \partial\psi_i^- + \psi_i^- \partial\psi_i^+{:} \ . \tag{4.19}$$

Denote by $\mathfrak{a}$ the 24-dimensional vector space spanned by the fermions. Since fermions allow for both periodic and anti-periodic boundary conditions, there exist two sectors in the theory. The antiperiodic (Neveu-Schwartz) sector contains a single ground state $|0\rangle$ and excitations of half-integer weight, while the periodic (Ramond) sector contains integral-weight excitations and has 2^{12} degenerate ground states. The degeneracy is due to the Clifford algebra satisfied by the zero modes,

$$\left\{\psi_{i,0}^{\pm}, \psi_{j,0}^{\pm}\right\} = 0 \ , \quad \left\{\psi_{i,0}^{\pm}, \psi_{j,0}^{\mp}\right\} = \delta_{ij} \ , \tag{4.20}$$

which moreover commute with L_0. As a result, one can build the Ramond ground states by acting with $\psi^-_{i,0}$ on a ground state $|s\rangle$ satisfying $\psi^+_{i,0}|s\rangle = 0$. Namely, the Ramond ground states are given by the mononomials

$$\psi^-_{i_1,0} \cdots \psi^-_{i_k,0}|s\rangle \ , \tag{4.21}$$

which form a spinor in twenty-four dimensions with Euclidean signature.

Next we want to construct an action of Co_0 on the states described above. To do so, recall that $\mathrm{Co}_0 \cong \mathrm{Aut}(\Lambda)$, so the Conway group is isomorphic to a subgroup of $SO(24)$ and we can make the natural identification $\mathfrak{a} = \Lambda \otimes_{\mathbb{Z}} \mathbb{C}$, i.e. let fermions "live" on the Leech lattice. Then consider a group element $g \in \mathrm{Co}_0$ with complex eigenvalues $\lambda_i^{\pm 1}$, and choose the basis of $\mathfrak{a}$ such that the fermions $\psi^\pm_i$ are acted upon as eigenvectors:

$$g\psi^\pm_i = \lambda_i^{\pm 1}\psi^\pm_i \ , \quad \lambda_i \equiv e^{2\pi i a_i} \ , \quad i = 1, \dots, 12 \ . \tag{4.22}$$

Moreover, since the ground states in the Ramond sector form a representation of the Clifford algebra associated to $\mathfrak{a}$, we should lift $G < SO(24)$ to a subgroup $\hat{G} < \mathrm{Spin}(\mathfrak{a})$. An element $x \in \mathrm{Spin}(\mathfrak{a})$ has the property $xux^{-1} \in \mathfrak{a}$ for $u \in \mathfrak{a}$. We define the *lift* $\hat{g} \in \hat{G} < \mathrm{Spin}(\mathfrak{a})$ of $g \in G < SO(\mathfrak{a})$ by requiring that it results in the same action as g when acting on $\mathfrak{a}$,

$$\hat{g}(u) := \hat{g}u\hat{g}^{-1} = gu \ , \quad \forall \ u \in \mathfrak{a} \ . \tag{4.23}$$

The map $u \mapsto \hat{g}(u)$ is a linear transformation on $\mathfrak{a}$ belonging to $SO(\mathfrak{a})$, so $\hat{g} \mapsto \hat{g}(\cdot)$ defines a map $\mathrm{Spin}(\mathfrak{a}) \to SO(\mathfrak{a})$ with kernel $\{\pm\mathbf{1}\}$, i.e. $\mathrm{Spin}(\mathfrak{a})$ is a double cover of $SO(\mathfrak{a})$. It turns out that for $G \cong \mathrm{Co}_0$ there exists a unique lift $\hat{G} \cong Co_0$ (see [77] for more details).

While the NS ground state $|0\rangle$ is invariant under Co_0, the group action on the 2^{12} Ramond ground states turns out to be

$$\hat{g}|s\rangle = \prod_{i=1}^{12} e^{\pi i a_i}|s\rangle = \nu|s\rangle \ , \quad \nu \equiv \prod_{i=1}^{12} \nu_i \ , \quad \nu_i \equiv e^{\pi i a_i} = \lambda_i^{1/2} \ , \tag{4.24}$$

where $|s\rangle$ is the ground state described in (4.21). Notice that a priori there is a sign ambiguity for ν_i, since it is the square root of λ_i. But actually the choice of sign is unique since the lift of Co_0 is unique. There is a further ambiguity in the definition of the g-action on the fermions, in that we can swap the complex eigenvalues. This translates into setting $\lambda_i \leftrightarrow -\lambda_i^{-1}$ in (4.22), and is referred to as a choice of polarisation.

The last step is to consider a $\mathbb{Z}_2 = \{1, \mathfrak{z}\}$ orbifold of the theory described so far, acting as $\mathfrak{z}\psi^\pm_i = -\psi^\pm_i$ on the fermions. In other words, it acts as $(-1)^F$ where F is the fermion number. Supposing that it acts trivially on both ground states $|0\rangle$ and $|s\rangle$ [77], it splits the two sectors into even/odd eigenspaces,

$$\mathrm{NS} = \mathrm{NS}^0 \oplus \mathrm{NS}^1 \ , \quad \mathrm{R} = \mathrm{R}^0 \oplus \mathrm{R}^1 \ , \tag{4.25}$$

where the eigenvalues of $\mathrm{NS}^j/\mathrm{R}^j$ are given by $(-1)^j$. From this point on, one can construct two closely related SVOAs. A useful description is by exploiting the fact that NS^0 forms a (bosonic) VOA on its own, that of the lattice D_{12}. Equivalently, it is the VOA associated to the affine Kac-Moody algebra $\widehat{\mathfrak{so}}(24)_1$, at level 1. The latter has four irreducible integrable modules, namely the vacuum module $A \cong \mathrm{NS}^0$, the vector module V, the spinor module S and the conjugate spinor module C. By extending the D_{12} VOA NS^0 by either of the spinor modules, one arrives at two SVOAs,

$$\begin{aligned} V^{f\natural} &= \mathrm{NS}^0 \oplus S \cong \mathrm{NS}^0 \oplus \mathrm{R}^0 \\ V^{s\natural} &= \mathrm{NS}^0 \oplus C \cong \mathrm{NS}^0 \oplus \mathrm{R}^1 \ . \end{aligned} \tag{4.26}$$

From the orbifold point of view we have the identifications $S \cong \mathrm{R}^0$ and $C \cong \mathrm{R}^1$ in our notation.

The two SVOAs $V^{f\natural}$ and $V^{s\natural}$ are isomorphic as SVOAs, and are uniquely characterized by their central charge $c_{V^{f\natural}} = c_{V^{s\natural}} = 12$ and the absence of weight 1/2 states. In [76] is was shown that the $N = 1$ supercurrent of $V^{f\natural}$ is fixed by a subgroup of Spin(24) isomorphic to Co_0, which is identified by the group $\hat{G}$ in the notation above. In particular, note that $Z(\mathrm{Spin}(24)) \cong \mathbb{Z}_2 \times \mathbb{Z}_2$ where the first $\mathbb{Z}_2$ factor can be identified with the kernel of Spin(24) → $SO(24)$ and the latter with the center of $SO(24)$. The centre $Z(\hat{G}) \cong \mathbb{Z}_2$ can be identified with the second $\mathbb{Z}_2$ in Z(Spin(24)), and has the same action as the $\mathbb{Z}_2$ in the orbifold construction. As a result, it follows immediately from (4.26) that Co_0 does not act faithfully on $V^{f\natural}$, since the latter is invariant under the action of the centre $Z(\hat{G})$. Instead, $V^{f\natural}$ carries a faithful action of the quotient group $\hat{G}/\mathbb{Z}_2 \cong Co_1$. On the other hand, Co_0 acts faithfully on $V^{s\natural}$, and this is ultimately the reason why we consider $V^{s\natural}$ instead of $V^{f\natural}$ in what follows. Another notable difference between $V^{f\natural}$ and $V^{s\natural}$ is that the $N = 1$ supercurrent in $V^{f\natural}$ fixed by Co_0 is not contained in $V^{s\natural}$, but rather in $V^{s\natural}_{\mathrm{tw}}$ (inside the R^0 part). A "canonically twisted" (or Ramond sector) module for $V^{s\natural}$ can also be constructed as

$$V^{s\natural}_{\mathrm{tw}} = \mathrm{NS}^1 \oplus \mathrm{R}^0 \ , \tag{4.27}$$

which is twisted with respect to the $Z(\hat{G})$ symmetry. The action of Co_0 on this twisted module is also faithful.

In order to formulate the Conway moonshine statement, first define the functions

$$\begin{aligned} \eta_{\pm g}(\tau) &:= q \prod_{n=1}^{\infty} \prod_{i=1}^{12} \left(1 \mp \lambda_i^{-1} q^n\right)\left(1 \mp \lambda_i q^n\right) \\ C_{\pm g} &:= \nu \prod_{i=1}^{12} \left(1 \mp \lambda_i^{-1}\right) = \prod_{i=1}^{12} \left(\nu_i \mp \nu_i^{-1}\right) \ . \end{aligned} \tag{4.28}$$

The twined partition functions of Conway moonshine are then given by

$$\begin{aligned} T^s_g(\tau) &:= \mathrm{str}_{V^{s\natural}} \left[\hat{g} q^{L_0 - 1/2}\right] = \mathrm{tr}_{V^{s\natural}} \left[\mathfrak{z} \hat{g} q^{L_0 - 1/2}\right] = \frac{\eta_g(\tau/2)}{\eta_g(\tau)} + \chi_g \\ T^s_{g,\mathrm{tw}}(\tau) &:= \mathrm{str}_{V^{s\natural}_{\mathrm{tw}}} \left[\hat{g} q^{L_0 - 1/2}\right] = \mathrm{tr}_{V^{s\natural}_{\mathrm{tw}}} \left[\mathfrak{z} \hat{g} q^{L_0 - 1/2}\right] = C_g \eta_g(\tau) - \chi_g \ , \end{aligned} \tag{4.29}$$

where the super-gradings can be defined by inserting $(-1)^F$ into the trace, whose action coincides with that of $\mathfrak{z}$ (recall that we identified $\mathbb{Z}_2 = \{1, \mathfrak{z}\}$ with the centre of Co_0). The main theorem of Conway moonshine states [77]:

Theorem 4.2. *The function $T^s_g(2\tau) = q^{-1} + O(q)$ is a Hauptmodul for a genus zero group $\Gamma_g < SL_2(\mathbb{R})$ that contains some $\Gamma_0(N)$, for every $g \in Co_0$. If g has a fixed point in its action on Λ, then $T^s_{g,tw}(\tau)$ is equal to the constant $-\chi_g$. Furthermore, if g has no such fixed point, then $T^s_{g,tw}(\tau)$ is also a Hauptmodul for a genus zero* *subgroup of* $SL_2(\mathbb{R})$.

In §8.3 we will see a prominent role played by Conway moonshine in relation to the symmetries of $K3$ CFTs.

5 Moonshine at weight one-half

Somewhat unexpectedly, a wave of moonshine development started in 2010 which led to the discovery of many more examples of moonshine connections. The modern examples share some similarities, but also display important differences with the classical moonshine examples discussed in §4. The modular objects in these examples are typically mock modular forms, an important and natural generalisation of modular forms introduced in §2.3, which furthermore have non-vanishing weights. The first and very fruitful arena that was explored is that of weight 1/2 mock modular forms. In this section we will describe interesting examples of moonshine relating finite groups and weight 1/2 mock modular forms.

5.1 Mathieu moonshine

The first example of the new type of moonshine, *Mathieu moonshine*, was initiated with certain observations about the weight 1/2 mock modular form H introduced in (2.42), in an analogous fashion as how observations about the classical J function initiated the development of monstrous moonshine. In [81] it was pointed out that the first few Fourier coefficients of H coincide with twice the dimensions of certain irreducible representations of the largest sporadic group M_{24}. Moreover, this observation was made in an interesting physical context which we will mention briefly below, and will explain in more detail in §8.

By now we have understood that, from many different points of view, Mathieu moonshine should really be thought of as a component of umbral moonshine, which we will review in the next subsection. However, in many ways Mathieu moonshine stands out among the other cases of umbral moonshine, not just historically but also in terms of its direct relation to the $K3$ elliptic genus. As a result, we will devote a separate subsection to Mathieu moonshine before discussing umbral moonshine.

Recall that the mock modular form H (2.42) can be viewed as arising from a meromorphic Jacobi form ψ given in (2.45). Using the relation between ψ and the $K3$ elliptic genus (2.44), as well as the identity $(\theta_{2,1}-\theta_{2,-1})(\tau,z) = -i\theta_1(\tau,2z)$, we obtain the following relation between the elliptic genus of $K3$ (cf. §3.3) and the mock modular form H:

$$\mathbf{EG}(\tau,z;K3) = \frac{\theta_1^2(\tau,z)}{\eta^3(\tau)}\left(24\,\mu(\tau,z)+H(\tau)\right)\ , \tag{5.1}$$

where

$$\mu(\tau,z) = -i\frac{\theta_1^2(\tau,z)}{\theta_1(\tau,2z)\eta^3(\tau)}\mathrm{Av}^{(2)}\left[\frac{y+1}{y-1}\right] = \frac{-iy^{1/2}}{\theta_1(\tau,z)}\sum_{\ell=-\infty}^{\infty}\frac{(-1)^\ell y^\ell q^{\ell(\ell+1)/2}}{1-yq^\ell}\ . \tag{5.2}$$

Note that while none of the two summands at the right-hand side of (5.1) transforms modularly, their modular anomalies cancel and the left-hand side is a perfectly well-behaved Jacobi form, as discussed in §2 and §3.3. In particular, a simple way to derive the shadow of H is by studying the modular properties of the Appell–Lerch sum $\mu(\tau,z)$ [21,82]. We will see in §8.1-8.2 the two interesting physical interpretations of the above splitting (5.1) of $\mathbf{EG}(K3)$, one in terms of the characters of $\mathcal{N}=4$ superconfomal algebra and one in terms of the elliptic genus of du Val singularities.

The aforementioned observation on the conspicuous relation between the first few coefficients of the mock modular form H and certain representations of M_{24} led to the suspicion that there exists a $\mathbb{Z}$-graded, infinite-dimensional M_{24}-module $K=\bigoplus_{n=1}^{\infty}K_n$ underlying H, namely $H(\tau)=q^{-\frac{1}{8}}\big(-2+\sum_{n=1}^{\infty}q^n\,(\dim(K_n)\big)$. A natural question is thus whether the other summand in the splitting of the Jacobi form $\mathbf{EG}(K3)$ (5.1) harbors an action of M_{24} as well. A simple guess arises from the fact that M_{24} is a subgroup of the permutation group S_{24} and as a result has a defining permutation representation $\mathbf{R}$, of dimension 24. A natural proposal for the "twined" version of (5.1) is therefore

$$\phi_g(\tau,z)=\frac{\theta_1^2(\tau,z)}{\eta^3(\tau)}\left((\mathrm{Tr}_{\mathbf{R}}\,g)\,\mu(\tau,z)+H_g(\tau)\right)\ , \tag{5.3}$$

where H_g denotes the graded characters of the M_{24} module K. Following the spirit of monstrous moonshine, we say that there is a non-trivial moonshine connection if all such ϕ_g transform nicely as Jacobi forms under some $\Gamma_g\subseteq SL_2(\mathbb{Z})$. Physical considerations reviewed in §3.2 moreover suggest that $\Gamma_0(|g|)\subseteq\Gamma_g$.

Fortunately, the possibility for this type of Jacobi forms is very limited and we are constrained to consider

$$\phi=c\,\phi_{0,1}+F\,\phi_{-2,1}\ , \tag{5.4}$$

where $\phi_{0,1}$ and $\phi_{-2,1}$ are given in (2.31), $c\in\mathbb{C}$, and F is a weight two modular form for Γ_g, possibly with a non-trivial multiplier system when $c=0$. The dimension of the space of possible F is often small for the $SL_2(\mathbb{Z})$-subgroup Γ_g we are interested in. For instance, when $\Gamma_g=SL_2(\mathbb{Z})$ the only possible weight two form is $F=0$. Hence, knowing the first few of the Fourier coefficients of ϕ_g, dictated by our guesses for the first few M_{24}-representations, is often sufficient to fix the whole function. As a result, not long after the original observation [81], candidates for the McKay–Thompson series were proposed for all conjugacy classes $[g]\subset M_{24}$ in [83–86], and they take the form

$$\phi'_g(\tau,z)=\frac{\mathrm{Tr}_{\mathbf{R}}\,g}{12}\,\phi_{0,1}(\tau,z)+\tilde{T}_g(\tau)\,\phi_{-2,1}(\tau,z)\ , \tag{5.5}$$

where the functions $\tilde{T}_g(\tau)$ are weight 2 modular forms explicitly specified in the references given above and collected in Table 2 of [87]. More precisely, these ϕ_g for any $g\in M_{24}$ are weak Jacobi form of weight zero and index one satisfying the elliptic invariance $\phi_g|_1(\lambda,\mu)=\phi_g$ for all $(\lambda,\mu)\in\mathbb{Z}^2$ (cf. (2.22)), and transform as

$$\phi'_g(\tau,z)=\rho_{n_g|h_g}(\gamma)\,e\left(-\frac{cz^2}{c\tau+d}\right)\phi'_g\big(\frac{a\tau+b}{c\tau+d},\frac{z}{c\tau+d}\big)\ ,$$

for $\gamma\in\Gamma_0(|g|)$, where the multiplier $\rho_{n_g|h_g}$ is summarised in [87].

In terms of the weak Jacobi forms (5.5), the main statement of Mathieu moonshine is the following.

Conjecture 5.1. *There exists a naturally defined $\mathbb{Z}$-graded, infinite-dimensional M_{24} module $K=\bigoplus_{n=1}^{\infty}K_n$ such that for any $g\in M_{24}$, the graded character*

$$H_g(\tau):=q^{-\frac{1}{8}}\big(-2+\sum_{n=1}^{\infty}q^n\,(\mathrm{Tr}_{K_n}\,g)\big) \tag{5.6}$$

satisfies $\phi_g = \phi'_g$, *where* ϕ_g *is as defined in* (5.3) *and* ϕ'_g *is the explicitly given weak Jacobi form* (5.5). *Moreover, the representations* K_n *are even in the sense that they can all be written in the form* $K_n = k_n \oplus k_n^*$ *for some* M_{24}*-representations* k_n *and their dual representation* k_n^*.

A proof of the key fact in the above conjecture, namely the existence of an M_{24}-module $K = \bigoplus_{n=1}^{\infty} K_n$ such that (5.8) holds, has been attained in [88]. However, a construction of the module K, analogous to the construction of $V^\natural$ by Frenkel–Lepowsky–Meurman in the case of monstrous moonshine, is still absent. Therefore in no way do we know why K should be "natural". As explicit data, the first few Fourier coefficients of the q-series $H_g(\tau)$ and the corresponding M_{24}-representations are given in [87].

Note that the above implies that there is a M_{24}-supermodule underlying all terms in the q-, y-expansion of the $K3$ elliptic genus. It is hence tempting to endow the McKay–Thompsen series ϕ_g with the physical interpretation as twined elliptic genera of $K3$ CFT (cf. (3.35)). This (im)possibility will be extensively discussed in §8. Finally, note that the modular form property of ϕ_g, as well as the mock modular property of $\mu(\tau, z)$, immediately lead to the fact that H_g are also mock modular forms. Explicitly, they are given by

$$H_g(\tau) = \frac{\mathrm{Tr}_{\mathbf{R}}\, g}{24} H(\tau) - \frac{\tilde{T}_g(\tau)}{\eta(\tau)^3} \,, \tag{5.7}$$

and they are weight 1/2 mock modular forms with shadows given by $(\mathrm{Tr}_{\mathbf{R}}\, g)\eta^3(\tau)$, generalising the mock modular property of $H(\tau)$ discussed around (2.43).

5.2 Umbral moonshine

A few years after the discovery of Mathieu moonshine, it was realised that it is in fact just one instance of a larger system of moonshine, called "umbral moonshine" [89,90]. There are in total 23 instances of umbral moonshine, which admit a uniform description (see Figure 2). The main statement of umbral moonshine is as follows.

Conjecture 5.2. *Let* G^X *be one of the 23 finite groups specified in* (5.9), m *be the corresponding positive integer specified in* (5.14), *and* I^X *be the specific subset of* $\{1, 2, \ldots, m-1\}$ *described in* (5.15). *Then there exists a naturally defined bi-graded, infinite-dimensional* G^X*-module*

$$K^X = \bigoplus_{r \in I^X} \bigoplus_{\substack{D \le 0 \\ D = r^2 \bmod 4m}} K^X_{r,D}$$

such that for any $g \in G^X$ *and for any* $r \in I^X$, *the graded character ("corrected" by a polar term* $-2q^{-\frac{1}{4m}}$ *as in below) coincides with the component* $H^X_{g,r}$ *of a vector-valued mock modular forms* $H^X_g = (H^X_{g,r})_{r \in I^X}$:

$$H^X_{g,r} = -2q^{-\frac{1}{4m}}\delta_{r,1} \; + \sum_{\substack{D \le 0 \\ D = r^2 \bmod 4m}}^{\infty} q^{-D/4m}\, (\mathrm{Tr}_{K^X_{r,D}}\, g). \tag{5.8}$$

In what follows we will briefly describe the specification of the main players, the finite groups G^X and the mock modular forms H^X_g, in the above conjecture. See Figure 2.

The starting point of this uniform construction are the 23 Niemeier lattices N^X introduced in §1.3. Recall that they are uniquely labelled by their root systems. We will denote by X the root systems, by N^X the corresponding Niemeier lattices, and by G^X the finite groups arising from the automorphisms $\mathrm{Aut}(N^X)$ via (1.13):

$$G^X := \mathrm{Aut}(N^X)/\mathrm{Weyl}(X) \tag{5.9}$$

These are the finite groups relevant for umbral moonshine and we will refer to them as the *umbral groups*.

On the modular side, we use the root system X to specify certain mock modular forms related to the finite group G^X. To explain how this is done, first recall that the McKay–Thompson series T_g in monstrous moonshine and the mock modular forms H_g in Mathieu moonshine have very special properties. First, once their (mock) modular data (consisting of the group Γ_g, the weight, and the multiplier) are specified, the functions are completely determined by the analyticity property of how they grow near the cusps $i\infty \cup \mathbb{Q}$. Second, they have "optimal growth" in the following sense. These functions 1) are bounded at all cusps that are not Γ_g-equivalent to $i\infty$ and 2) have the slowest possible growth near $i\infty$ that is compatible with the modular data. For instance, in the case of monstrous moonshine it is elementary to see that a modular form satisfying condition 1) for $\Gamma_g \supset \langle T\rangle$ must behave like $q^{-n}(1+O(q))$ for some integer n near the cusp $i\infty$. As a result, the condition 2) states that $n = 1$, which is indeed the case for the moonshine functions T_g. Another way to state the above is to say that the functions in monstrous and Mathieu moonshine can be written in terms of Rademacher sums over the minimal polar term in the expansion near $i\infty$ [67, 91]. See also §4.1 for a discussion on Rademacher sums.

The functions of umbral moonshine turn out to have analogous uniqueness properties, and the relevant concept here is the notion of optimal mock Jacobi forms. We will first focus on the case $g = e$ and $\Gamma_g = SL_2(\mathbb{Z})$. Let $\psi = \sum_r h_r\theta_{m,r}$ be a mock Jacobi form of weight one and index m. We say it is an optimal mock Jacobi form if

$$h_r(\tau) = O(q^{-\frac{1}{4m}}) \tag{5.10}$$

as $\Im(\tau) \to \infty$, for each $r \in \mathbb{Z}/2m$. For instance, the function ψ^{3E_8} defined in §2.3 is an optimal mock Jacobi since it has index 30 and $H_1^{3E_8}(\tau) = -2q^{-\frac{1}{120}}(1+O(q))$, while $H_7^{3E_8}$ vanishes at $\Im(\tau) \to \infty$ (cf. (2.38)). Similarly, ψ^{24A_1} is an index 2 optimal mock Jacobi form.

At weight one, the space of such optimal mock Jacobi forms turns out to be very restricted: the mock modular transformation property together with the pole structure of the functions near the cusps are sufficient to determine the whole q-series. In particular, they can be obtained as simple Rademacher sums involving only the polar parts as input. Such forms are even more scarce if we want them to have non-transcendental Fourier coefficients. Note that this must be the case for the function to play a role in moonshine, since the graded dimensions are necessarily integers and of course non-transcendental. In [15] it is shown that if ψ is such a form, it must lie in a 34-dimensional space, irrespective of its index. Moreover, inside this 34-dimensional space there are 39 special elements (which span the 34-dimensional space) distinguished by their special symmetries. Recall that Atkin–Lehner symmetries normalising $\Gamma_0(m)$ are specified by a subgroup K of the group of exact divisors Ex_m (cf. (4.6)). Given such a pair m and K, we say that an index m mock Jacobi form ψ is *K-symmetric* if

$$\psi = \sum_{r \bmod 2m} h_r \theta_{m,r} = \sum_{r \bmod 2m} h_r \theta_{m,a(n)r} \quad \text{for all } n \in K \ , \tag{5.11}$$

where, for a given n, we define $a(n)$ to be the unique element in $\mathbb{Z}/2m$ satisfying

$$a(n) = \begin{cases} 1 \bmod 2m/n \\ -1 \bmod 2n \end{cases} .$$

Note that the symmetry is an involution, since $a^2 = 1 \bmod 2m$. For instance, the mock Jacobi form ψ^{3E_8} introduced in (2.38) is invariant under the action of $K = \{1, 6, 10, 15\} < \mathrm{Ex}_{30}$, corresponding to $a(n) = 1, 11, 19, 29$. The surprising result in [15] then states that a non-vanishing K-symmetric index m optimal mock Jacobi form at weight one has non-transcendental coefficients if and only if the corresponding $SL_2(\mathbb{R})$ subgroup Γ^{m+K} defines a genus zero quotient in the upper-half plane. Recall that these genus zero groups also play an important role in monstrous moonshine. Note that we necessarily need to have $m \notin K$ (referred to as the "non-Fricke" property) for the mock Jacobi form to be non-vanishing, since at weight one has $\sum_r h_r \theta_{m,r} = -\sum_r h_r \theta_{m,-r}$ and $a(m) = -1$. There are just 39 such non-Fricke genus zero groups $\Gamma^{m+K} < SL_2(\mathbb{R})$ and we will denote the corresponding unique optimal mock Jacobi form, with the normalisation

$$h_1 = -2q^{-\frac{1}{4m}}(1 + O(q)) \ , \tag{5.12}$$

by ψ^{m+K}. In fact, these 39 distinguished optimal mock Jacobi forms ψ^{m+K} turn out to have Fourier coefficients that are not only non-transcendental, but also integral. Moreover, 23 among the 39 have positive coefficients in the following sense. By writing (cf. (2.28))

$$\psi = \sum_{1 \leq r \leq m-1} h_r \hat{\theta}_{m,r} \ ,$$

h_r has the expansion

$$h_r = \begin{cases} -2q^{-1/4m} + \sum_{n \geq 0} c_{r,n} q^{n/4m}, & \text{if } r^2 = 1 \bmod 4m \\ \sum_{n \geq 0} c_{r,n} q^{n/4m}, & \text{otherwise} \end{cases} , \tag{5.13}$$

with $c_{r,n} \in \mathbb{Z}_{\geq 0}$. This positivity property makes it possible for it to be the graded dimensions of finite group representations[3]. To sum up, for any index, there are 23 special mock Jacobi forms of weight one for $SL_2(\mathbb{Z})$ distinguished by

1. the optimality growth condition (5.10),
2. the Atkin–Lehner symmetries (5.11),
3. the normalisation (5.12),
4. the positivity and integrality of the coefficients (5.13).

---

[3] It is believed [15] that the remaining 16 optimal mock Jacobi forms ψ^{m+K} with positive and negative integral coefficients have also umbral type moonshine attached to them, but with additional supermodule structure that accounts for the minus sign.

The interesting observation is that these ψ^{m+K} with positivity properties are in one-to-one correspondence with the 23 Niemeier root systems X! To explain this correspondence, first recall the ADE classification of the modular invariant combination of $\widehat{A_1}$ affine Lie algebras [47], which has led to a classification of $\mathcal{N}=2$ superconformal minimal models with spectral flow symmetries. Their classification gives rise to a square matrix Ω^Y of size $2m$ for each simply-laced root system Y, where m coincides with the Coxeter number of Y. Moreover, the term $(\Omega^Y_{r,r}-\Omega^Y_{r,-r})$ coincides with the multiplicity of r as a Coxeter exponents (the degrees of the invariant polynomials shifted by one) of Y and takes values in $\{0,1,2\}$. The above can be generalised to a union of simply-laced root systems with the same Coxeter number (recall that this is indeed the case for Niemeier root systems) $X=\cup_i Y_i$ by defining $\Omega^X=\sum_i \Omega^{Y_i}$. Then the mock Jacobi form $\psi^X=\psi^{m+K}$, with theta-decomposition $\psi^X=\sum_r H^X_r\theta_{m,r}$, corresponding to the Niemeier root system X, display the following relations to X.

1. The Coxeter number of X coincides with the index of the ψ^X,

$$m=\mathrm{Cox}(X)\ . \tag{5.14}$$

2. The matrix Ω^X and the form $\psi^X=\psi^{m+K}$ have the same Atkin–Lehner symmetries: $(\Omega^X)_{r,r'}=(\Omega^X)_{r,a(n)r'}$ for all $n\in K$. Using these symmetries, it is convenient to define a set I^X of the orbits of the Atkin–Lehner symmetry group acting on $\{1,\dots,m-1\}$ (in $\mathbb{Z}/2m$), labelling the independent components H^X_r of the vector-valued mock modular form (H^X_r) and leading to

$$\psi^X=\sum_{r\in I^X}H^X_r\sum_{n\in K}\hat{\theta}_{m,a(n)r}\ . \tag{5.15}$$

3. The shadow of ψ^X is determined by Ω^X. More precisely, the completion of ψ^X is specified by the skew-holomorphic Jacobi form $\sigma=\sum_r\overline{\theta^1_{m,r}}\Omega^X_{r,r'}\theta_{m,r'}$ (cf. (2.37) and the preceeding text).

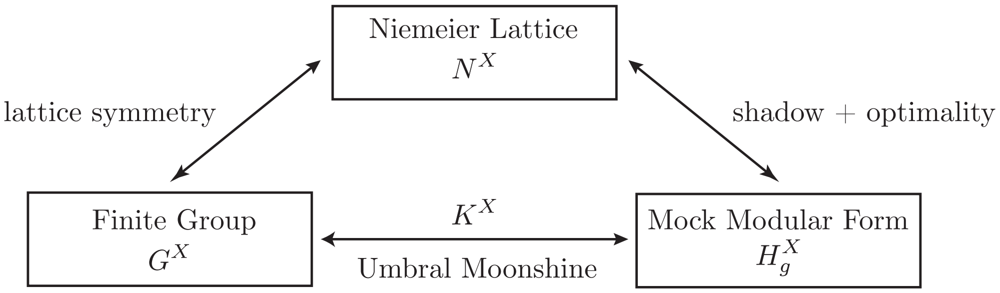
The description of ψ^{24A_1} and ψ^{3E_8} in §2.3 provides examples of the above. The mock Jacobi form ψ^X then gives us the vector-valued mock modular forms $H^X=(H^X_r)$ which will play the role of graded dimensions of the module for the umbral group G^X. In other words, we have $H^X_r=H^X_{e,r}$ in Conjecture 5.2. For the case $X=24A_1$ this is the Mathieu moonshine function ψ^{24A_1} we discussed in §2 and §5.1. Another simple example is when for $X=12A_2$, where $\psi^X=\sum_{r=1,2}H^X_r\hat{\theta}_{3,r}$ (so $m=3$ and $I^X=\{1,2\}$), with

$$\begin{aligned}H^X_1(\tau)&=2q^{-1/12}(-1+16\,q+55\,q^2+144\,q^3+\dots)\\H^X_2(\tau)&=2q^{8/12}(10+44\,q+110\,q^2+\dots).\end{aligned} \tag{5.16}$$

At the same time, the symmetries of the corresponding Niemeier lattice gives $G^X\cong 2.M_{12}$. The relation between the finite group G^X and the vector-valued mock modular form H^X can be observed from the fact that the group $2.M_{12}$ has irreducible representations of dimensions $16,55,144$ as well as $10,44,110$.

After specifying the mock Jacobi forms for $SL_2(\mathbb{Z})$, in order to describe the moonshine relation we also need a set of mock Jacobi forms $\psi^X_g=\sum_r H^X_{g,r}\theta_{m,r}$, one for each conjugacy class $[g]\subset G^X$, for subgroups of $SL_2(\mathbb{Z})$. The mock modular forms $H^X_g=(H^X_{g,r})$ will then play the role of graded characters of the umbral moonshine module, as described in Conjecture 5.2. This can be achieved in a way

Figure 2: The construction of umbral moonshine.



largely analogous to the $SL_2(\mathbb{Z})$ case, though additional subtleties do emerge and extra care needs to be taken. We refer to [92] for more details.

Once the mock modular forms H_g^X are specified, it is trivial to verify the existence of the G^X-module $K_{r,D}^X$ in Conjecture 5.2 term by term, namely one D at a time. Moreover, the existence of the whole umbral module $K^X = \bigoplus_r \bigoplus_D K_{r,D}^X$ has been proven mathematically using properties of (mock) modular forms [88,93]. However, the construction, or even an understanding of the exact nature of K^X, is not yet obtained in general. Construction of K^X has so far only been achieved for certain particularly simple cases of umbral moonshine, corresponding to Niemeier root systems $3E_8$ [94], $4A_6$ and $2A_{12}$ [95], $4D_6$, $3D_8$, $2D_{12}$ and D_{24} [96], as well as $6D_4$ [97]. The construction in [94] relies on special identities satisfied by the mock modular forms $H_{g,r}^{3E_8}$ relating it to a lattice-type sum, while in [95,96] the modules are constructed using the interpretation of the meromorphic Jacobi forms associated to Ψ_g^X as the twined partition function of certain vertex operator algebras (or chiral CFTs). In [97] the module for the $6D_4$ case of umbral moonshine is constructed by exploiting the relation between the (twined) $K3$ elliptic genus, umbral and Conway moonshine, which we will explain in §8.2. Moreover, generalised umbral moonshine, analogous to the generalised monstrous moonshine discussed in §4.1, has been established in [98], hinting that some elements of CFT/modular tensor category structure should be present at the umbral moonshine module K^X. Despite these results, it is fair to say that a uniform construction of the umbral module, reflecting the uniform description of umbral moonshine, is currently one of the biggest challenges in the study of moonshine.

We will end our review on umbral moonshine by noting a special property, called *discriminant property*, of umbral moonshine. It relates the discriminants D (the power of individual terms $q^{-D/4m}$ in the q-series H_r^X) and the number field generated by the characters of representations showing up in $K_{r,D}^X$. For instance, in the case $X = 24A_1$, the M_{24}-representation underlying the $q^{7/8}$ term in $H_g = H_{g,1}^{24A_1}$ is $K_{-7}^{24A_1} = \rho \oplus \rho^*$, where ρ is a 45-dimensional irreducible representation and ρ^* is the dual representation. At the same time, $\mathrm{Tr}_\rho\, g$ (and hence also $\mathrm{Tr}_{\rho^*}\, g$) generates the field $\mathbb{Q}(\sqrt{-7})$. Analogous relations continue for larger q-power as long as $\mathbb{Q}(D) = \mathbb{Q}(-7)$, and similar properties hold uniformly for all 23 cases of umbral moonshine. At present there is no physical understanding of this surprising and profound-looking property.

5.3 Thompson moonshine

The Thompson sporadic group Th is a subgroup of the Monster that has order $|Th| \sim 9 \cdot 10^{16}$ and contains 48 conjugacy classes. Thompson moonshine describes a special relation between the representation theory of Th and certain weakly holomorphic modular forms of weight 1/2. It was first discussed in [99] and is the first instance of the so-called *skew-holomorphic moonshine* [100] relating skew-holomorphic Jacobi forms and finite group representations. See §2.2 and §9 for more mathematical and physical information on skew-holomorphic Jacobi forms.

Just like Mathieu and umbral moonshine, Thompson moonshine relates finite groups connected to the Monster (cf. §1.3) and weight 1/2 modular objects. However, there are a few differences. First, the modular objects in Thompson moonshine are modular while in umbral moonshine they are mock modular with non-vanishing shadows. Second, there is a super-structure in the Thompson moonshine module, i.e. the representations come with signs. See Conjecture 5.3. That said, this extra $\mathbb{Z}_2$-grading structure is very simple and completely controlled by m mod 4, where m is the natural $\mathbb{Z}$-grading corresponding to the exponents of q in the moonshine function. Finally, we remark that Thompson moonshine also enjoys a discriminant property analogous to that of umbral moonshine.

To describe Thompson moonshine, we start with the following conjecture [99]:

Conjecture 5.3. *There exists a $\mathbb{Z}$-graded Th-supermodule (cf. (1.20))*

$$W = \bigoplus_{\substack{m \geq -3 \\ m \equiv 0,1 \bmod 4}}^{\infty} W_m \tag{5.17}$$

such that the graded dimensions of W_m are related to a certain weight 1/2 weakly holomorphic modular form $\mathcal{F}_3$ (5.20) by

$$\mathcal{F}_3(\tau) = \sum_{\substack{m=-3 \\ m \equiv 0,1 \bmod 4}} \mathrm{Str}_{W_m}(1) q^m \ . \tag{5.18}$$

Furthermore, the associated McKay-Thompson series

$$\mathcal{F}_{3,g}(\tau) = \sum_{\substack{m=-3 \\ m \equiv 0,1 \bmod 4}} \mathrm{Str}_{W_m}(g) q^m \ , \tag{5.19}$$

are given by certain weakly holomorphic weight 1/2 modular forms, with $\mathcal{F}_{3,e} = \mathcal{F}_3$. Finally, W_m is even under the superspace $\mathbb{Z}_2$-grading if $m \geq 0$ and $m \equiv 0 \bmod 4$ or when $m = -3$, and is odd otherwise.

Let's discuss the elements of this conjecture. The function $\mathcal{F}_3$ is defined by

$$\mathcal{F}_3(\tau) := 2f_3(\tau) + 248\theta(\tau) \ , \tag{5.20}$$

where $\theta(\tau)$ is the Jacobi theta function discussed in §2.1. We next describe the specification of f_3.

Define the Kohnen-plus space $M^+_{1/2}$ as the set of functions that transform like θ, and additionally satisfy the condition $c(n) = 0 \ \forall \ n \neq 0, 1 \bmod 4$ in their Fourier expansions $\sum c(n)q^n$. It can be shown that in fact $M^+_{1/2}$ is one-dimensional, spanned by θ itself. However, if we allow for poles at the cusps, we can get a nontrivial space

$M^{!,+}_{1/2}$ of weakly holomorphic modular forms of weight 1/2 in the Kohnen-plus space. In [101], Zagier constructed an infinite-dimensional basis for $M^{!,+}_{1/2}$, spanned by the (unique) functions

$$f_d(\tau) = q^{-d} + \sum_{n>0} A(n,d) q^n \ , \quad d \equiv 0, 3 \bmod 4 \ , \tag{5.21}$$

where $f_0 = \theta$. Here we are mainly interested in the case $d = 3$. Using uniqueness, it is easy to show that f_3 can be explicitly specified as

$$f_3(\tau) = -\frac{1}{20}\left(\frac{[\theta(\tau), E_{10}(4\tau)]}{\Delta(4\tau)} + 608\theta(\tau) \right) = q^{-3} - 248q + 26752q^4 - \dots \ , \tag{5.22}$$

where $E_{10} = E_4 E_6$ is the weight 10 Eisenstein series and Δ is the weight 12 cusp form introduced in §2.1. The *Rankin-Cohen bracket* is defined by $[f, g] := kfDg - lgDf$, with $D = \frac{1}{2\pi i}\frac{d}{d\tau}$ and k, l being the weights of the modular forms f, g, respectively.

Thompson moonshine was initiated by the observation that the first few Fourier coefficients of f_3 can be expressed in terms of the dimensions of irreducible representations of *Th*. For example $1 = 1$, $248 = 248$ and $26752 = 27000 - 248$. It is worth noting that this connection between f_3 and *Th* had already appeared in the context of generalised monstrous moonshine [74, 102, 103], cf. §4.1. Specifically, the centraliser of the class $3C$ of $\mathbb{M}$ is isomorphic to $\mathbb{Z}_3 \times Th$ [63], and consequently the twisted module $V^{\natural}_{3\mathrm{C}}$ carries a natural action of *Th*. The corresponding twisted generalised character is given by the so-called *Borcherd's lift* of f_3,

$$Z(3\mathrm{C}, e; \tau) = q^{-\frac{1}{3}} \prod_{n>0} (1 - q^n)^{A(n^2,3)} \ . \tag{5.23}$$

Notice however that the above connection to generalised monstrous moonshine is limited only to the coefficients $A(n^2, 3)$ of f_3, which does not explain why the rest of its coefficients also exhibit a relation to *Th*. To do better, the insight of [99] is to "correct" the function by including additional contributions from the theta function $\theta(\tau)$, and consider instead

$$\mathcal{F}_3(\tau) := 2f_3(\tau) + 248\theta(\tau) = 2q^{-3} + 248 + 2 \cdot 27000q^4 - 2 \cdot 85995q^5 + \dots \ , \tag{5.24}$$

which belongs to the Kohnen plus space. Note that the alternating signs correspond to the superspace structure mentioned in Conjecture 5.3.

The McKay–Thompson series $\mathcal{F}_{3,g}$ of Thompson moonshine have a structure very similar to the above. Schematically, they can be most naturally viewed as a sum of two contributions

$$\mathcal{F}_{3,g} = \text{Projected Rademacher Sum} + \theta\text{-corrections} \ , \tag{5.25}$$

where the first term is the Rademacher sum of the unique polar term $2q^{-3}$ for the suitable group Γ_g and multiplier system, projected onto the Kohnen plus space, and the second term again involves linear combinations of $\theta(d^2\tau)$, where d are certain integers compatible with the group Γ_g. We refer to [99], and in particular [104] for more details.

It is interesting to note that the modular objects in Thompson moonshine enjoy a close relation to the so-called traces of singular moduli, which are important quantities in number theory. As mentioned in the final example of §2.3, the generating functions of the traces of singular moduli turn out to have interesting modular properties [101]. In particular, we have

$$A(n,3) = \frac{1}{\sqrt{n}} \sum_{Q\in\mathcal{Q}_{-3n}/\,PSL_2(\mathbb{Z})} \chi_{n,-3}(Q)J(\alpha_Q)\ , \quad n\in\mathbb{Z}_+\ , \tag{5.26}$$

coinciding with the Fourier coefficients of the modular form f_3 which participates in Thompson moonshine. In the above, $\chi_{n,-3}$ denotes a certain genus character whose precise definition can be found in [101]. An analogous relation to traces of singular moduli can be established also at higher level, when one only keeps track of $\Gamma_0(N)$-equivalences of quadratic forms.

6 Moonshine at weight three-halves

This is an arena for moonshine that is currently in rapid development. As a result we will be very brief and just highlight a few key features and prospects of the recent developments.

After the fruitful explorations in moonshine at weight one-half, it is natural to wonder about the landscape of moonshine in the dual weight, $w = 2 - \frac{1}{2} = \frac{3}{2}$. Weight $\frac{3}{2}$ mock modular forms are much less constrained than their weight $\frac{1}{2}$ counterparts, and they turn out to provide a fertile ground to study the connections to finite groups, already giving us the *O'Nan moonshine* [105] and the *class number moonshine* [106], the latter involving the Hurwitz-Kronecker class number mock modular form described in (2.48).

It is more likely than not that there are more treasures in weight 3/2. Here we limit ourselves to commenting on the two established moonshine examples.

We will point out three conspicuous properties of the two examples of moonshine at weight three-halves[4].

Supermodules. In monstrous and Conway moonshine discussed in §4, the underlying modules are "real" modules (as opposed to supermodules (1.20)) and the group characters involved are ordinary traces (as opposed to supertraces). The same is true in Mathieu and umbral moonshine, up to the polar terms in (5.8) which have negative coefficients but do not carry any non-trivial information on group representations. In Thompson moonshine we encounter supermodules, but only in a rather trivial way: the supermodule is purely even or purely odd depending on whether the corresponding q-power is $+1$ or -1 mod 4. In particular, in weight one-half we do not encounter moonshine examples in which Fourier coefficients of mock modular forms are given by differences of traces of group representations, i.e. in every homogeneous component the supermodule is always either even or odd.

In weight three-halves this is no longer true and the super-ness of the supermodules is an intrinsic and unavoidable property of the two moonshine examples we discuss.

---

[4] In fact, these properties make the weight 3/2 connections so different from the moonshine examples at weight zero and weight one-half, such that one might wonder whether we should still use the term "moonshine" for them.

Cusp forms. In the moonshine examples we discussed so far, the (mock) modular objects involved are very distinguished in that they are essentially uniquely determined by their modularity and analyticity properties. In particular, the graded characters of monstrous and Conway moonshine are Hauptmoduls and can be written as, up to an additive constant, Rademacher sums with a single polar term q^{-1}. The graded characters of umbral (including Mathieu) and Thompson moonshine are also (projected) Rademacher sums up to addition of theta functions (cf. (5.25) and [92]). The latter can arguably be viewed as a minor correction since the coefficients of theta functions are vanishing at almost all exponents (vanishing unless the exponenets are square numbers up to a specific rescaling) and they do not carry any interesting number theoretic information.

This crucial uniqueness property, which serves to distinguish mock modular forms for weight zero and weight one-half moonshine, is no longer the relevant criterion in weight three-halves moonshine. The mock modular forms in O'Nan and class number moonshine involve weight 3/2 cusp forms in a very pronounced way. (See the end of §2.1 for the definition of cusp forms.)

This property opens the door to connecting with arithmetic geometry, a totally different area in mathematics. The main ingredients of this connection are: 1) The Waldspurger-type relation among coefficients of weight 3/2 newforms and the special L-values of the corresponding weight two newforms under the so-called Shimura correspondence [107]. 2) The modularity theorem relating the L-function of elliptic curves and that of certain weight two newforms. 3) The (strong form of) Birch and Swinnerton-Dyer conjecture (and its proven elements) relating special L-values of the elliptic curves and their important arithmetic data including the order of the Tate-Shafarevich group. See [108–110]. 4) The congruences among the moonshine modular objects stemming from the congruences among the characters which is a basic property of finite group representations. Combining the above ingredients, the connections between weight 3/2 cusp forms and finite groups lead to an infinite sequence of statements on the p-part of the Tate-Shafarevich group, organised by the finite group structure. Moreover, in class number moonshine the torsion subgroups of the elliptic curves (and other Abelian varieties in general) attached to certain modular data play an important role in the construction of moonshine mock modular forms. Exploring the implication of the finite group structure in mock modular forms in arithmetic geometry is an interesting new mathematical direction in the study of moonshine.

New finite groups. The above two properties , regarding the finite group and the modular form sides of the moonshine connection respectively, makes it possible for weight three-halves moonshine to encompass new types of finite groups into the realm of moonshine.

O'Nan moonshine, as the name suggests, connects a set of weight 3/2 mock modular forms to the O'Nan group. The O'Nan group was discovered in 1976 in the midst of the intense developments related to the classification of finite groups, and is one of the 6 pariah groups not related to the Monster. The class number moonshine, on the other hand, delivers a family of infinitely many weight 3/2 mock modular forms arising from Hurwitz–Kronecker class numbers (2.47), which accommodates representations of *infinitely many groups*. Recall that, apart from the sporadic groups there are three infinite families in the classification of finite simple groups, and one of them is the cycle groups $\mathbb{Z}_p$ of prime order p. It turns out that for each prime number p one has a mock modular form $\mathcal{H}_{p,1}$ of level 4, a scalar multiple of the class number mock modular form $\mathcal{H}$ (2.48), and a mock modular form $\mathcal{H}_{p,p}$ of level $4p$, such that they coincide with the two graded characters of a $\mathbb{Z}$-graded supermodule for $\mathbb{Z}_p$. Apart from this infinite family of groups, it has also been shown in [106] that mock modular forms at different levels (given by 4 times the order of the group elements) conspire to encode supermodules for interesting Mathieu groups.

These instances of weight three-halves moonshine greatly broaden the horizon of connections between modular objects and finite groups. All instances of moonshine at weight zero and one-half are connected to groups related to the Monster, but the O'Nan and the class number examples show that this does not have to be the case. In these examples it was demonstrated that a pariah sporadic group as well as one of the 3 infinite families of non-sporadic finite simple groups are also related to (mock) modular forms in a similar way! This suggests the tantalising possibility that moonshine-type connections are in fact ubiquitous and an intrinsic property in the landscape of modular objects and finite groups, and that the latter is an important organising structure of the former.

Last but not least, these new connections, involving supermodules of infinitely many groups, pose interesting challenges to physics. Can physics still provide the finite group modules and an explanation for these connections? If so, what are the relevant physical systems that can give rise to these supermodules?

Part III

Moonshine and string theory

String theory has been playing a key role in moonshine from its earliest years, starting with the string-inspired proof of monstrous moonshine by Borcherds (cf. §4.1). String theory is also expected to play an interesting role in the understanding of Mathieu and umbral moonshine, and we hope that moonshine can teach us something novel and important about certain aspects of string compactification. More generally speaking, the connection to physics is one of the key reasons why many string theorists and mathematicians find moonshine exciting. In this part we will discuss some of these connections. In §7 we outline the relation between monstrous moonshine and certain (1+0)-dimensional string compactification. In §8, the main section of this part, we summarise the known relations between various moonshines and $K3$ compactifications. Finally we briefly mention some other connections discussed recently in §9.

7 Monstrous moonshine

In this section we briefly describe a recent string theory construction, developed in [111, 112], involving the monstrous moonshine module $V^\natural$ and the associated twisted module $V_g^\natural$ discussed in §4.1. Although the striking genus zero property of monstrous moonshine has been mathematically proven, its physical interpretation has remained elusive for a long time. The recent work [111, 112] sheds light on this important property by considering certain heterotic string theory compactifications down to $0 + 1$ dimensions.

In [111, 112], one takes as the starting point a compactification down to $1 + 1$ dimensions where the internal CFT, which has central charge $(24, 12)$, is given by $V^\natural \times V^{s\natural}$. The second factor is the Conway module introduced in §4.2, which plays mostly the role of the spectator whose main function is to provide the right-moving $\mathcal{N} = 1$ supersymmetry of the world-sheet theory. This model turns out to have $\mathcal{N} = (0, 24)$ spacetime supersymmetry in two-dimensions. We further compactify the remaining spatial direction on a circle. This additional compactification is crucial for computing the "BPS index" described below and for the construction of more general models. More generally, for each $g \in \mathbb{M}$ one constructs a CHL-like model by orbifolding the theory by a symmetry which acts on $V^\natural$ as g and on the circle as a shift of order dictated by certain properties of the action of g on $V^\natural$ (and coincides with the order of g in the simplest cases). To avoid subtleties involving gravitational anomalies, this theory should be considered at the zero-string coupling limit.

In [111] it is shown that the (first-quantized) BPS states of the above models form a module of the generalised Kac-Moody algebras $\mathfrak{m}_\mathfrak{g}$, which is the monster algebra constructed by Borcherds for $g = e$ and the "twisted" monster algebras constructed by Carnahan for $g \neq e$ [75, 103, 113]. See also the discussion on generalised monstrous moonshine in §4.1. We are interested in the (twined) BPS index counting spacetime BPS states in these theories. Denote the relevant Hilbert space by $\mathcal{H}^g_{\text{BPS}}$, we define

$$Z_{(g,h)}(T, U) := \text{Tr}_{\mathcal{H}^g_{\text{BPS}}} \left((-1)^F e^{2\pi i TW} e^{2\pi i UM}\right) \ , \tag{7.1}$$

where g, h are commuting elements of the Monster. In the above, $T, U \in \mathbb{H}$ are complexified chemical potentials for the winding and momentum quantum numbers W, M respectively, with the imaginary parts scaling according to the inverse temperature and radius as

$$\mathrm{Im}T \sim \beta R\ , \quad \mathrm{Im}U \sim \frac{\beta}{R}\ . \tag{7.2}$$

Using the Fock space construction of $\mathcal{H}^g_{\mathrm{BPS}}$ by allowing for an arbitrary number of free strings, as well as the twisted denominator formula, relating an infinite product to an infinite sum and generalising the Koike–Norton–Zagier formula (4.14), one obtains

$$\begin{aligned} Z_{(e,g)}(T,U) &= \left(T_{(e,g)}(T) - T_{(e,g)}(U)\right)^{24} \\ Z_{(g,e)}(T,U) &= \left(T_{(e,g)}(T) - T_{(g,e)}(U)\right)^{24}\ . \end{aligned} \tag{7.3}$$

Note that $T_{(e,g)} = T_g$ is the McKay–Thompson series of the monstrous moonshine.

The above expressions lead to a physical interpretation of the modularity and the genus zero property of monstrous moonshine. First, it was shown in [111], using the techniques developed in [114], that the self-duality group (i.e., a subgroup of the T-duality group mapping between the same CHL model but generically at different values of the moduli) involves two subgroups of $SL_2(\mathbb{R})$, acting on T and U independently in (7.3). In particular, the $SL_2(\mathbb{R})$ subgroup acting on T is nothing but Γ_g, the associated genus zero group in monstrous moonshine (cf. Conjecture 4.1). As a result, the physical invariance of the BPS index under self-duality group immediately leads to the Γ_g-invariance modularity property of the moonshine function $T_g(T)$. Second, recall that the Hauptmodul property of $T_{(e,g)}$ can be recast in the claim that they have only a single pole at $\tau \to i\infty$ and its images under Γ_g. In terms of the supersymmetric index, this means that $Z_{(g,e)}(T,U)^{1/24}$ and its T-duality images will diverge as $T \to i\infty$, for fixed U. Using the T-duality

$$Z_{(e,g)}(T,U) = -Z_{(e,g)}\left(-\frac{1}{U}, -\frac{1}{T}\right)$$

and the generalised moonshine relation between $T_{(g^ah^c,g^bh^d)}(\tau)$ and $T_{(g,h)}\left(\frac{a\tau+b}{c\tau+d}\right)$ (cf. §4.1), this property gets translated to the statement that for all co-prime integers a and b, $Z_{(g^a,g^b)}(T,U)$ is divergent in the limit $U \to i\infty$ with T fixed, if and only if this limit is related to the limit of $T \to i\infty$ with U fixed by a self-duality of the CHL model associated to $g \in \mathbb{M}$. Now we will argue why this is true from physical considerations. Let us interpolate between the two limits by varying the radius R, while fixing the inverse temperature β to be large. At the low temperature limit, the divergence at the limit $T \to i\infty$ with U fixed is caused by the ground state contribution $e^{\beta R}$, which blows up as $R \to \infty$. The small radius limit is convergent unless there is a phase transition and a new ground state with contribution $e^{\beta/R}$ emerges at the other side of the critical line. If this happens, one can show that there is an $SU(2)$ symmetry at the self-dual radius limit on the critical line, which in particular contains the T-duality. In other words, the two sides of the critical line are related by a self-duality contained in Γ_g, and this proves the Hauptmodul property.

8 Moonshine and $K3$ string theory

As mentioned in §5, Mathieu moonshine was first noticed in the context of $K3$ sigma models and was later recognised as being one of the twenty-three cases of umbral moonshine. As we will discuss shortly, all instances of umbral moonshine, not just Mathieu moonshine, enjoy a close relation to $K3$ elliptic genus, the quantity that captures the BPS states of $K3$ sigma models, and more generally BPS states of superstring theory compactifications involving $K3$ surfaces. This tentative connection to $K3$ string theories is what makes Mathieu and umbral moonshine so interesting for many string theorists.

This is because $K3$ manifolds have the special property that they are the only non-trivial (i.e. non-toroidal) Calabi–Yau manifolds in two (complex) dimensions, and the resulting string theory compactifications are much more manageable than compactifications on generic Calabi–Yau three-folds due to higher amount of supersymmetries, and contain much richer structure and information than toroidal compactifications which are for many purposes too simple to be useful. As a result, $K3$ compactifications have been playing a prominent role throughout the development of string theory, being the playground for developing revolutionary new ideas including black hole microstates counting [115] and AdS/CFT correspondence [116]. Furthermore, they also feature in important dualities relating different string theories.

In this section we will review the observed relation between moonshine and $K3$ sigma models, and outline the challenges to be overcome in order to understand the origin of this relation and to find a physical system which provides the much wanted uniform construction of the umbral moonshine module. Finally, we will summarise the different ideas that aim to address these challenges, along with their current status.

8.1 Mathieu moonshine and $K3$ elliptic genus

As mentioned in §3.3, the Calabi-Yau property of $K3$ together with the Jacobi form property dictates that its elliptic genus is given by $2\phi_{0,1}$ in terms of the familiar weak Jacobi form (2.31). Recall that $K3$ is the only Calabi-Yau two-fold besides the four-torus. It possesses the special property that it is not only Kähler but also admits a hyper-Kähler structure. As a result, the $U(1)$ symmetry of the $\mathcal{N}=2$ superconformal algebra discussed in §3.3 can be extended to $SU(2)$, and the sigma model has enhanced $\mathcal{N}=4$ superconformal symmetry for both the left and the right movers. This leads to a specific decomposition of the elliptic genus of an $\mathcal{N}=4$ SCFT that we will now explain.

Since the underlying CFT admits an action by the $\mathcal{N}=4$ superconformal algebra, the Hilbert space decomposes into a direct sum of (unitary) irreducible representations of this algebra. Hence the elliptic genus (3.34) can be written as a sum of characters of representations of this algebra with some multiplicities. A natural embedding of the $U(1)$ current algebra of the $\mathcal{N}=2$ superconformal algebra into the $SU(2)$ current algebra of the $\mathcal{N}=4$ superconformal algebra is obtained by choosing $J_0^3 \sim J_0$. As a result, the $\mathcal{N}=4$ highest weight representations are again labelled by two quantum numbers h,ℓ, corresponding to the operators L_0, J_0^3 respectively, and the character of such an irreducible representation $V_{h,\ell}$ is defined as

$$ch_{h,\ell}(\tau,z) := \mathrm{Tr}_{V_{h,\ell}}\left((-1)^{J_0}y^{J_0}q^{L_0-c/24}\right).$$

For the central charge $c=6$, there are two supersymmetric (also called ‘BPS’ or ‘massless’) representations in the Ramond sector, and they have the quantum numbers

$$h = \tfrac{1}{4}\ ,\ \ell = 0, \tfrac{1}{2}\ .$$

Their characters have been computed to be [117–119]

$$\begin{aligned} ch_{\frac{1}{4},0}(\tau,z) &= \frac{\theta_1^2(\tau,z)}{\eta^3(\tau)}\mu(\tau,z)\,, \\ ch_{\frac{1}{4},\frac{1}{2}}(\tau,z) &= q^{-\frac{1}{8}}\frac{\theta_1(\tau,z)}{\eta^3(\tau)} - 2\frac{\theta_1(\tau,z)^2}{\eta^3(\tau)}\mu(\tau,z)\,, \end{aligned} \tag{8.1}$$

where $\mu(\tau,z)$ is the so-called Appell-Lerch sum defined in (5.2).

Notice that the supersymmetric representations have non-vanishing Witten index

$$ch_{\frac{1}{4},0}(\tau,z=0) = 1\,, \quad ch_{\frac{1}{4},0}(\tau,z=0) = -2\,.$$

The non-supersymmetric (or ‘non-BPS’ or ‘’) representations have

$$h = \tfrac{1}{4} + n\,, \quad \ell = \tfrac{1}{2}\,, \qquad n = 1,2,\dots,$$

and their characters are given by

$$ch_{\frac{1}{4}+n,\frac{1}{2}}(\tau,z) = q^{-\frac{1}{8}+n}\frac{\theta_1^2(\tau,z)}{\eta^3(\tau)}\,. \tag{8.2}$$

By definition, their contribution to the Witten index vanishes, $ch_{\frac{1}{4}+n,\frac{1}{2}}(\tau,z=0) = 0$. This is why the Witten index only receives contribution from quantum states that are of the form ($\text{massless}_L \times \text{massless}_R$) in terms of $\mathcal{N}=4$ representations, while the elliptic genus receives contribution from ($\text{massless}_L \times \text{massless}_R$) as well as ($\text{massive}_L \times \text{massless}_R$).

We are now ready to describe the first physical interpretation of the specific way (5.1) of decomposing the $K3$ elliptic genus, which makes the connection to M_{24} manifest. From (5.1) and (8.1)-(8.2), we see that $\mathbf{EG}(K3)$ can be expressed as

$$\mathbf{EG}(K3) = 20\,ch_{\frac{1}{4},0} - 2\,ch_{\frac{1}{4},\frac{1}{2}} + \sum_{n=1}^{\infty} c_H(n)\,ch_{\frac{1}{4}+n,\frac{1}{2}} \tag{8.3}$$

where

$$H(\tau) = q^{-1/8}\left(-2 + \sum_{n=1}^{\infty} c_H(n)q^n\right) = 2q^{-\frac{1}{8}}\left(-1 + 45\,q + 231\,q^2 + 770\,q^3\dots\right)\ , \tag{8.4}$$

is the mock modular form given in (2.42). In particular, the multiplicities $c_H(n)$ of the massive multiplets are equal to the dimensions of the homogeneous component of the M_{24}-module K according to Mathieu moonshine Conjecture 5.2.

As mentioned already in §5.1, it is then tempting to identify ϕ_g (5.3), encoding the McKay–Thompson series of Mathieu moonshine H_g, as the elliptic genus twined by certain symmetries of the $K3$ non-linear sigma model whose action preserves the $\mathcal{N}=4$ SCA. While this is possible for some $g \in M_{24}$, this interpretation is proven to fail for some other group elements. We will discuss this in §8.4.

8.2 Umbral moonshine and $K3$ elliptic genus

As alluded to before, the $\mathcal{N}=4$ decomposition is not the only possible interpretation for the splitting (5.1) of the elliptic genus, into the part coming directly from the moonshine mock modular form and the contribution from the Appell-Lerch sum μ. A second interpretation, in terms of the elliptic genus of singular spaces labelled by ADE root systems, yields the same result in this case but the difference is that it can be readily generalised to the other 22 cases of umbral moonshine.

Recall that, for each of the 23 Niemeier lattices N^X, uniquely determined by its root system X, umbral moonshine associates a finite group G^X and a weight one mock Jacobi form $\psi_g^X = \sum_r H_{g,r}^X \hat{\theta}_{m,r}$ for each $g \in G^X$. In [120], it was shown that there are 23 ways of splitting $\mathbf{EG}(K3)$ into two part:

$$\mathbf{EG}(K3;\tau,z) = \mathbf{EG}(X;\tau,z) + \frac{\theta_1^2(\tau,z)}{2\eta^6(\tau)}\left(\frac{1}{2\pi i}\frac{\partial}{\partial w}\psi^X(\tau,w)\right)\Big|_{w=0} \tag{8.5}$$

where $\psi^X = \psi_e^X$ is the optimal mock Jacobi form given in §5.2, encoding the graded dimension of the umbral moonshine module. In the above formula, $\mathbf{EG}(X;\tau,z)$ denotes the holomorphic part of the elliptic genus of the singularities corresponding to the root system of N^X. See also the remark at the end of §3.3. Note that a common definition of the $K3$ surface is that it has at worst du Val type surface singularities, i.e. singularities of the complex plane of the form $\mathbb{C}^2/G$, where G is a finite subgroup of $SU(2)_{\mathbb{C}}$. These singularities have an ADE classification, in accordance with the famous McKay correspence. A conformal field theory description of string theory with these ADE singularities as the target space was given in [121]. The form of their elliptic genus was investigated in a number of papers, including [24,27,29–31,120,122]. For instance, when N is the Niemeier lattice with root system $24A_1$, we have

$$\mathbf{EG}(N;\tau,z) := 24\,\mathbf{EG}(A_1;\tau,z)\ ,$$

defined to be 24 times the holomorphic part of the elliptic genus of an A_1-singularity. One has

$$\mathbf{EG}(A_1;\tau,z) = ch_{\frac{1}{4},0}(\tau,z) = \frac{\theta_1^2(\tau,z)}{\eta^3(\tau)}\mu(\tau,z). \tag{8.6}$$

As a result, the splitting (5.1) of the elliptic genus can also be interpreted as coming from two contributions, one from the singularity elliptic genus corresponding to the root system $X = 24A_1$, and one from the umbral moonshine function ψ^{24A_1}. Different from the $\mathcal{N}=4$ character interpretation, this interpretation of the splitting is applicable for all 23 cases of umbral moonshine. In other words, (8.5) is really 23 equalities, corresponding to all 23 Niemeier lattices N^X.

This interpretation suggests a twined version of the function $\mathbf{EG}(K3;\tau,z)$ by twining the right-hand side of the equality (8.5):

$$\phi_g^X(\tau,z) := \mathbf{EG}_g(X;\tau,z) + \frac{\theta_1^2(\tau,z)}{\eta^6(\tau)}\left(\frac{1}{2\pi i}\frac{\partial}{\partial w}\psi_g^X(\tau,w)\right)\Big|_{w=0}\ , \tag{8.7}$$

where g can be any element of G^X. The first term on the right-hand side is the (holomorphic part of the) twined elliptic genus of the corresponding singularity sigma model. This can be computed explicitly, since we know the G^X–action on the Niemeier root system X, which translates into an G^X–action on the singularity

CFT that preserves its superconformal structure, and leads to a definition of its twined elliptic genus. The second term, on the other hand, is directly provided by the McKay–Thompson series of umbral moonshine. It is easy to check that this definition of ϕ_g^X for $N = N^{24A_1}$ leads to the same weak Jacobi forms as in (5.3) for the case of Mathieu moonshine. Just like in the case of Mathieu moonshine, it is then tempting to interpret all the functions ϕ_g^X arising from umbral moonshine as in (8.7), as the elliptic genus twined by certain symmetries of the $K3$ non-linear sigma model whose action preserves the $\mathcal{N} = 4$ SCA.

For some of the $g \in G^X$, such an interpretation is not availble, as we will discuss in §8.4. In particular, only subgroups of G^X which preserve a four-plane, i.e. a four-dimensional oriented subspace within $N^X \otimes_{\mathbb{Z}} \mathbb{R}$, will acquire a role as a symmetry group of $K3$ sigma models. For later use, for a given Niemeier lattice $N = N^X$ with non-trivial root system, we will denote the set of Jacobi forms arising from (8.7) by

$$\Phi(N^X) := \{\phi_g^X \mid g \text{ is a four-plane preserving element of } G^X\}\ . \tag{8.8}$$

8.3 Conway moonshine and $K3$ elliptic genus

Recall the construction of the twisted Conway module $V_{\rm tw}^{s\natural}$ described in §4.2. Given a fixed n-dimensional subspace in $\Lambda \otimes_{\mathbb{Z}} \mathbb{C}$, there are different ways to build $U(1)$ currents by considering bilinear combinations of the 24 fermions [78, 79]. In this theory, one can construct a $U(1)$ current J of level 2 from fermions associated to a four-plane, i.e. a subspace of (real) dimension four. Given such a four-plane Π, fixing the $U(1)$ current and the SVOA structure, breaks the symmetry of $V_{\rm tw}^{s\natural}$ from Co_0 to its subgroup preserving Π. Conversely, given a four-plane preserving $G < Co_0$, one can construct a $U(1)$ current J such that $V_{\rm tw}^{s\natural}$, when equipped with a module structure for J and for the $\mathcal{N} = 1$ superconformal algebra, has symmetry G.

Interestingly, the $U(1)$-charged graded character of $V_{\rm tw}^{s\natural}$ coincides with $\mathbf{EG}(K3)$ (up to a sign) [78]. More generally, one can consider the $U(1)$-graded character of the twisted Conway module twined by a four-plane preserving element of Co_0 (see §4.2 for notation):

$$\phi_g^\Lambda := -\,\mathrm{Tr}_{V_{\rm tw}^{s\natural}}\left[\mathfrak{z}\ \hat{g}\ y^{J_0} q^{L_0-\frac{c}{24}}\right], \tag{8.9}$$

where J_0 is the zero mode of the $U(1)$ current. Explicitly, it is given by

$$\begin{aligned}\phi_g^\Lambda(\tau,\zeta) = \frac{1}{2}\Bigg[&\frac{\theta_3(\tau,\zeta)^2}{\theta_3(\tau,0)^2}\frac{\eta_{-g}(\tau/2)}{\eta_{-g}(\tau)} - \frac{\theta_4(\tau,\zeta)^2}{\theta_4(\tau,0)^2}\frac{\eta_g(\tau/2)}{\eta_g(\tau)} \\ &- \frac{\theta_2(\tau,\zeta)^2}{\theta_2(\tau,0)^2} C_{-g}\eta_{-g}(\tau) - \frac{\theta_1(\tau,\zeta)^2}{\eta(\tau)^6} D_g \eta_g(\tau)\Bigg]\ ,\end{aligned} \tag{8.10}$$

where most special functions were defined in (4.28). The function D_g is defined by

$$D_g := \nu \sideset{}{'}\prod_{i=1}^{12}\left(1-\lambda_i^{-1}\right) = \sideset{}{'}\prod_{i=1}^{12}\left(\nu_i - \nu_i^{-1}\right). \tag{8.11}$$

where in $\prod'$ one skips the two pairs of eigenvalues associated with the fixed four-plane, for which $\lambda_i^{\pm 1} = 1$. Notice that D_g is non-vanishing if and only if it fixes exactly a four-plane and not more. In the latter case, D_g is determined up to a sign by the eigenvalues of g, since we are free to exchange what we call λ_i and λ_i^{-1}. As a result, for exactly four-plane preserving elements there are in fact two choices of ϕ_g^Λ, depending on the choice of the sign of D_g, and we define

$$\begin{aligned}\phi_{g,\epsilon}^\Lambda(\tau,\zeta) := \frac{1}{2}\Bigg[&\frac{\theta_3(\tau,\zeta)^2}{\theta_3(\tau,0)^2}\frac{\eta_{-g}(\tau/2)}{\eta_{-g}(\tau)} - \frac{\theta_4(\tau,\zeta)^2}{\theta_4(\tau,0)^2}\frac{\eta_g(\tau/2)}{\eta_g(\tau)} \\ &-\frac{\theta_2(\tau,\zeta)^2}{\theta_2(\tau,0)^2}C_{-g}\eta_{-g}(\tau) - \epsilon\,\frac{\theta_1(\tau,\zeta)^2}{\eta(\tau)^6}\,|D_g|\,\eta_g(\tau)\Bigg]\ ,\end{aligned} \tag{8.12}$$

where $\epsilon = \pm 1$ encodes the sign ambiguity of D_g.

In all cases, it was shown in [78] that the $\phi_{g,\epsilon}^\Lambda$ are Jacobi forms of weight 0 and index 1, at some level, for every $g \in Co_0$ that fixes at least a four-plane. For future use, denote the set of all these functions by

$$\Phi(\Lambda) := \left\{\phi_{g,+}^\Lambda, \phi_{g,-}^\Lambda \mid g \text{ is a four-plane preserving element of } Co_0\right\}\ . \tag{8.13}$$

We will mention a few observations about this set of functions and those arising from umbral moonshine, the $\Phi(N^X)$ defined in (8.8). First, these sets of functions notably have a large overlap: quite often Conway and umbral moonshine give rise to the same weak Jacobi form, albeit via very different ways. An important difference is that a weak Jacobi form ϕ_g^X can be defined for all $g \in G^X$ via umbral moonshine (8.7), while in the Conway case one has to restrict to four-plane preserving elements (in order to obtain a Jacobi form of index one). Second, the functions that only appear in $\Phi(\Lambda)$ tend to be realised as twined elliptic genera of $K3$ sigma models on the sub-loci in the moduli space where the model admits a description as T^4-orbifold. Note also that the geometry of T^4-orbifold connects nicely to the free field orbifold construction of the Conway module. In fact, $V_{\rm tw}^{s\natural}$ is isomorphic to the $\mathbb{Z}_2$ orbifold of a certain T^4 model, when one "forgets" about the distinction between left- and right-movers, roughly speaking [78, 123, 124]. Third, the functions that only arise from umbral and not from Conway moonshine have the property that they must correspond to a symmetry which acts differently on the left- and right-movers of a $K3$ sigma model [125]. We will discuss the connections between the moonshine symmetry groups and the stringy $K3$ symmetry groups in the next subsection.

8.4 Symmetries of $K3$ string theory and moonshine

In the previous subsections we have seen a close mathematical relation between the $K3$ elliptic genus and the functions of umbral and Conway moonshine. It is therefore natural to compare the moonshine groups and the symmetries of $K3$ sigma models. In fact, it was known that symmetries of $K3$ surfaces have a close relation to sporadic groups. In particular, a celebrated theorem by Mukai [126] established the role of M_{23}, one of the 26 sporadic groups and a subgroup of M_{24}, as the finite group that "organises" the symmetries of $K3$ surfaces. More precisely, in [126] it was shown that there is of a bijection between (isomorphism classes of) M_{23} subgroups with at least five orbits and (isomorphism classes of) finite groups of $K3$ symplectomorphisms. A generalisation of this classical result to "stringy $K3$ geometry" was initiated by Gaberdiel, Hohenegger, and Volpato, who in [127] classified the symmetry groups of all (non-singular) $K3$ sigma model using lattice techniques in a method closely following the simplified proof of the Mukai theorem by Kondo [128]. From the spacetime (D-branes) point of view, the results of [127] can be viewed as classifying symplectic autoequivalences (symmetries) of derived categories on $K3$ surfaces [129]. See also [130] for a related discussion on symmetries of appropriately defined moduli spaces relevant for curve counting on $K3$. In [125] the classification was extended to theories corresponding to singular loci in the moduli space of $K3$ sigma models. This is necessary if one is interested in the full string theory and not just the sigma models. Despite the fact that the type IIA worldsheet theory behaves badly along these loci [131], the full type IIA string theory is not only completely well-defined but also possesses special physical relevance in connection to non-Abelian gauge symmetries. The spacetime gauge group is enhanced from $U(1)^{24}$ to some non-Abelian group at these loci, and the ADE type gauge group is given by the ADE type singularity of the $K3$ surface [131,132]. The existence of such loci with enhanced gauge symmetries in the moduli space, though not immediately manifest from the world-sheet analysis in type IIA, is clear from the the dual description in terms of heterotic T^4 compactification.

To state the classification result, let us first review some general properties of sigma models on K3 (see [133,134]). The moduli space of non-singular non-linear sigma models on $K3$ with $\mathcal{N} = (4,4)$ supersymmetry is given by an open subset in

$$\mathcal{M} = (SO(4) \times O(20)) \backslash O^+(4,20)/O^+(\Gamma^{4,20}) \; , \tag{8.14}$$

where $(SO(4) \times O(20)) \backslash O^+(4,20)$ is the Grassmannian of positive four-planes Π, a four-dimensional oriented positive-definite subspace within $\mathbb{R}^{4,20} \cong \Gamma^{4,20} \otimes_{\mathbb{Z}} \mathbb{R}$, and $\Gamma^{4,20}$ is the even unimodular lattice with signature $(4,20)$. In other words, choosing a point in the moduli space $\mathcal{M}$ is equivalent to choosing a four-plane inside $\Gamma^{4,20} \otimes_{\mathbb{Z}} \mathbb{R}$. The complement in $\mathcal{M}$ of this open subset is the set of singular four-planes Π (i.e. orthogonal to a root $v \in \Gamma^{4,20}$, $v^2 = -2$) and correspond to certain singular limits of sigma models on K3. The whole space $\mathcal{M}$ is also the moduli space of type IIA string theory at a fixed finite value of g_s. In the singular cases, the full supersymmetry-preserving symmetries of the corresponding type IIA string theory contains a continuous non-Abelian gauge symmetry which we will mod out to obtain the discrete symmetry group G_{IIA}. As a result, we have

$$G_{\text{IIA}}(\Pi) = \text{Stab}(\Pi)/\text{W} \tag{8.15}$$

where Stab(Π) is the subgroup of $O^+(\Gamma^{4,20})$ which stabilises the four-plane Π point-wise, and W is the Weyl group generated by reflections with respect to all root vectors orthogonal to Π, if there are any.

In [125] (Corollary 4) it was then shown that the groups G_{IIA}, realised somewhere in $\mathcal{M}$, are in bijection with the four-plane preserving subgroups of the twenty-four finite groups G_N associated to the twenty-four even self-dual lattices of rank twenty-four (cf. (1.13)), including the twenty-three umbral groups G^X and the Conway group Co_0. In particular, it means that generically the umbral group G^X, and in particular $G^{24A_1} \cong M_{24}$, cannot be the symmetry group of any individual $K3$ sigma model as they are not four-plane preserving subgroups of Co_0.

After classifying the symmetry groups as abstract groups, we would like to know how they act on the spectrum of supersymmetric states. This information is captured by the elliptic genera twined by these symmetries, as defined in (3.35). In [125], it was conjectured (among other finer conditions) that any twined $K3$ elliptic genus realised anywhere in the moduli space $\mathcal{M}$ coincides with at least one of the functions in one of the twenty-four sets of functions $\Phi(N)$ defined in (8.8) and in (8.13), where N is either one of the twenty-three Niemeier lattices N^X or the Leech lattice Λ. Conversely, it was conjectured that *all* elements of $\Phi(N)$ play a role in capturing the symmetries of BPS states of $K3$. Strong evidence for the above conjecture was recently found in [135] by considering string theories closely related (by orbifolding) to type IIA string theory compactified on $K3 \times T^2$, and requiring that the analyticity structure of the BPS-counting functions is compatible with the physics of wall-crossing. It is however not yet understood why umbral moonshine functions should have such a close relationship to $K3$ sigma model twined elliptic genera. See §8.5 for more discussions.

8.5 Beyond perturbative string theory

The most important lesson from the previous subsection is that supersymmetry-preserving symmetries of $K3$ CFTs are closely related to the symmetries of umbral moonshine, but fall short of explaining umbral moonshine: many umbral groups simply cannot be realised as symmetries of $K3$ sigma model anywhere in the moduli space. In particular, while the conjectures discussed in §8.4 state that all umbral and Conway moonshine functions associated to four-plane preserving group elements play a role as the twining genera of $K3$ sigma models, and in fact capture them completely, the physical relevance of the umbral (including Mathieu) moonshine functions corresponding to group elements preserving only a two-plane remains unclear. There is at the moment no consensus regarding what the precise physical setup relevant for umbral moonshine is. At the same time, it is precisely this necessity to go beyond perturbative string theory, and the possibility of having moonshine involved in non-perturbative setups such as stringy black holes, that makes the possible connections between umbral moonshine and string theory so exciting. Here we briefly discuss a few possibilities that have been discussed to different degrees in the literature.

Combining symmetries. The idea is to find a way to combine symmetries realised at different points in the moduli space and in this way generate a larger group which also contains two-plane preserving elements. This possibility was first raised as a question "Is it possible that these automorphism groups at isolated points in the moduli space of $K3$ surface are enhanced to M_{24} over the whole of moduli space when we consider the elliptic genus?" in [81]. It is motivated by the fact that the elliptic genus receives only contributions from BPS states and is invariant across the moduli space. Concrete steps towards realising this idea in the context of Kummer surfaces, i.e. $K3$ surfaces obtained as torus orbifolds $T^4/\mathbb{Z}_2$, were taken in [136–138] and further explored in [139]. In particular, it was shown that it is possible to combine the geometric symmetries of three specific Kummer surfaces, given by the groups

$$G_0 := \mathbb{Z}_2^4 \rtimes (\mathbb{Z}_2 \times \mathbb{Z}_2) \ , \quad G_1 := \mathbb{Z}_2^4 \rtimes A_4 \ , \quad G_2 := \mathbb{Z}_2^4 \rtimes S_3 \ . \tag{8.16}$$

into the so-called octad group $G = \mathbb{Z}_2^4 \rtimes A_8$. This is a maximal subgroup of M_{24} but too large to be the automorphism group of a single $K3$ sigma model. The work of [139] supplied evidence that G indeed acts on the twisted sector BPS states that survive after moving away from the Kummer loci in the moduli space. This suggests the possibility that G, a maximal subgroup of M_{24}, indeed acts as an "overarching" symmetry within the Kummer moduli space. Finally, see also [140] for a exploration of this idea in the context of Landau–Ginzburg models. A challenging aspect of this approach is that it is technically very hard to follow a path in the moduli space to a generic point which does not correspond to a torus orbifold or admits a

Landau–Ginzburg UV description. As a result it is not straightforward to combine symmetries which are realised in a generalised $K3$ sigma model.

Lower-dimensional compactifications. A second approach is to consider string compactifications where larger groups are realised at given points in the moduli space as symmetry groups of the full string theory (not just for the perturbative string states and not just the BPS sector). For theories with 16 supercharges, this is only possible for compactifications with less than six non-compact dimensions. This idea was first discussed in [83], where the implications of Mathieu moonshine for four-dimensional BPS black holes, arising in type II superstring theory compactified on $K3 \times T^2$, were explored. This idea was futher developed in [141], and has led to nice new insights into string dualities [114].

More recently, it was shown that there are points in the moduli space of string theory compactifications to three dimensions which admit the Niemeier groups as discrete symmetry groups [142]. In the type IIA frame, these are given by compactifications on $K3 \times T^3$. The action of these symmetry groups on the 1/2-BPS states of the theory has been analyzed [142], and it would be interesting to understand the action on the 1/4-BPS states. However, it is currently unclear how functions related to the umbral moonshine McKay–Thompson series can be obtained in this physical setup. Recently, a further compactification on $K3 \times T^4$ was also explored in [143].

Heterotic $K3$ compactifications. The plausibility of the relevance of this setup lies in the fact that its moduli space contains the moduli space of $\mathcal{N} = (4,4)$ $K3$ CFT as a sub-locus. It is hence imaginable that moving away from the sub-loci will allow us to see more symmetries. At a technical level, we have less means to compute the spectrum due to smaller number of supersymmetries. This route has been somewhat explored in [144, 145], but a lot remains to be done.

Five-brane dynamics. The connection between umbral moonshine and double scaled little string theory, describing the perturbative dynamics in the presence of NS five-branes in type IIB superstring theory, has been investigated in [146, 147]. This idea is natural in that it incorporates new non-perturbative elements (NS fivebranes) into the physical setup, and that the double scaled little string theories admit an ADE classification which also plays an important role in the construction of umbral moonshine. It would be interesting to understand the finite group symmetries present in this setup.

Relations to certain VOA. As we have seen in the previous subsections, umbral and Conway moonshine are related, as they are both closely related to $K3$ sigma models. In [79], a close variant of the Conway module is shown to exhibit an action of a variety of two-plane preserving subgroups of Co_0, including M_{23}, and yields as twining genera a set of weak Jacobi forms of weight zero and index two. In addition, the mock modular forms which display M_{23} representations appear to be very closely related to the mock modular forms which play a role in M_{24} moonshine. It might be fruitful to gain a deeper physical understanding of this apparent connection and see if one can "tweak" the better understood Conway module in some ways to accommodate the umbral modules.

Total unknown. As none of the above approaches has led to a definite answer so far, a possible scenario is that the connections we observed between $K3$ elliptic genera and umbral moonshine are just a coincidence and the physical context (if any) of umbral moonshine lies completely somewhere else.

Finding the correct physical setup in which the umbral moonshine modules can be constructed in a natural and uniform way is an active direction area and is currently the holy grail in the study of umbral moonshine.

9 Other connections

MSW strings. Another physical setup which delivers examples of modular objects connected to finite groups is M5 branes wrapping divisors of Calabi–Yau threefolds [18]. These give rise to effective strings, the so-called MSW strings, with (0,4) worldsheet supersymmetry [19]. In [18], it was pointed out that the generalised genera of the MSW string theories are examples of skew-holomorphic Jacobi forms (cf. §2.2), a type of modular object playing a starring role in the family of moonshine generalising the Thompson moonshine, but whose role in physics has thus far not been highlighted. In particular, the generalised elliptic genera for one or two M5 branes wrapping the surfaces $\mathbb{P}^2$, del Pezzo 8, and half-$K3$ were examined in [18]. In the first case, it was known that two M5 branes wrapping the surface $\mathbb{P}^2$ leads to mock skew-holomorphic forms that are closely related to the generating function of the class number mock modular form (2.48). This connection suggests the possibility that M5-branes on $\mathbb{P}^2$ give a starting point from which we may pursue a geometric understanding of Mathieu moonshine for (rescaled) Hurwitz class numbers described in §6.

For the other cases, one finds that a weight 3/2 modular form governing the generalised elliptic genus of a single M5 brane wrapping the del Pezzo 8 and half-$K3$ surfaces is $f^{(1)} = E_4\eta^{-5}$. See §2.1 for the definition of E_4 and η. In [18] it was shown that $f^{(1)}$ is the graded superdimension of a supermodule for the Mathieu group M_{12}, and the corresponding graded characters $f_g^{(1)}$ for all $g \in M_{12}$ are explicitly given. It would be very interesting to have a geometric and string theoretic understanding of this M_{12}-supermodule.

e-mail: reb@math.berkeley.edu

www home page www.math.berkeley.edu/˜reb

When I was a graduate student, my supervisor John Conway would bring his 1 year old son into the department, who was soon known as the baby monster. A more serious answer to the question is that the monster is the largest of the (known**) sporadic simple groups. Its name comes from its size: the number of elements is

$$\begin{aligned}&8080, 17424, 79451, 28758, 86459, 90496, 17107, 57005, 75436, 80000, 00000\\=&2^{46}.3^{20}.5^{9}.7^{6}.11^{2}.13^{3}.17.19.23.29.31.41.47.59.71,\end{aligned}$$

about equal to the number of elementary particles in the planet Jupiter.

The monster was originally predicted to exist by Fischer and by Griess in the early 1970's. Griess constructed it a few years later in an extraordinary tour de force as the group of linear transformations on a vector space of dimension 196883 that preserved a certain commutative but non-associative bilinear product, now called the Griess product.

Our knowledge of the structure and representations of the monster is now pretty good. The 194 irreducible complex representations were worked out by Fischer, Livingstone and Thorne (before the monster was even shown to exist) They take up 8 large pages in the atlas [A] of finite groups, which is the best single source of information about the monster (and other finite simple groups). The subgroup structure is mostly known; in particular there is an almost complete list of the maximal subgroups, and the main gaps in our knowledge concern embeddings of very small simple groups in the monster. If anyone wishes to multiply elements of the monster explicitly, R. A. Wilson can supply two matrices that generate the monster. But there is a catch: each matrix takes up about 5 gigabytes of storage, and to quote from Wilson's atlas page: "standard generators have now been made as 196882×196882 matrices over GF(2)... They have been multiplied together, using most of the computing resources of Lehrstuhl D für Mathematik, RWTH Aachen for about 45 hours...". (The difficulty of multiplying two elements of the monster is caused not so much by its huge size as by the lack of "small" representations; for example, the symmetric group S_{50} is quite a lot bigger than the monster, but it only takes a few minutes to multiply two elements by hand.) Finally the modular representations of the monster for large primes were worked out by Hiss and Lux; the ones for small primes still seem to be out of reach at the moment.

** The announcement of the classification of the finite simple groups about 20 years ago was a little over-enthusiastic, but a recent 1300 page preprint by Aschbacher and Smith should finally complete it.

In the late 1970's John McKay decided to switch from finite group theory to Galois theory. One function that turns up in Galois theory is the elliptic modular function

$$j(\tau) = q^{-1} + 744 + 196884q + 21493760q^2 + \cdots = \sum c(n)q^n$$

($q = e^{2\pi i\tau}$), which is essentially the simplest non-constant function invariant under the action $\tau \mapsto (a\tau + b)/(c\tau + d)$ of $SL_2(\mathbf{Z})$ on the upper half plane $\{\tau | \Im(\tau) > 0\}$. He noticed that the coefficient 196884 of q^1 was almost equal to the degree 196883 of the smallest complex representation of the monster (up to a small experimental error). The term "moonshine" roughly means weird relations between sporadic groups and modular functions (and anything else) similar to this. It was clear to many people that this was just a meaningless coincidence; after all, if you have enough large integers from various areas of mathematics then a few are going to be close just by chance, and John McKay was told that his observation was about as useful as looking at tea-leaves. John Thompson took McKay's observation further, and pointed out that the next few coefficients of the elliptic modular function were also simple linear combinations of dimensions of irreducible representations of the monster; for example, $21493760 = 21296876 + 196883 + 1$. He suggested that there should be a natural infinite dimensional graded representation $V = \sum_{n\in\mathbf{Z}} V_n$ of the monster such that the dimension of V_n is the coefficient $c(n)$ of q^n in $j(\tau)$, at least for $n \neq 0$. (The constant term of $j(\tau)$ is arbitrary as adding a constant to j still produces a function invariant under $SL_2(\mathbf{Z})$, and is set equal to 744 mainly for historical reasons.) Conway and Norton [C-N] followed up Thompson's suggestion of looking at the McKay-Thompson series $T_g(\tau) = \sum_n Trace(g|V_n)q^n$ whose coefficients are given by the traces of elements g of the monster on the representations V_n, and found by calculating the first few terms that they all seemed to be Hauptmoduls of genus 0. (A Hauptmodul is a function similar to j, but invariant under some group other than $SL_2(\mathbf{Z})$). Atkin, Fong, and Smith showed by computer calculation that there was indeed an infinite dimensional graded representation of the monster whose McKay-Thompson series were the Hauptmoduls found by Conway and Norton, and soon afterwards Frenkel, Lepowsky, and Meurman explicitly constructed this representation using vertex operators.

If a group acts on a vector space it is natural to ask if it preserves any algebraic structure, such as a bilinear form or product. The monster module constructed by FLM has a vertex algebra structure invariant under the action of the monster. Unfortunately there is no easy way to explain what a vertex algebra is; see [K] for the best introduction to them. Vertex algebras are a generalization of commutative rings with derivations (at least in characteristic 0). Roughly speaking they can be thought of as commutative rings with derivation where the ring multiplication is not quite defined everywhere; this is analogous to rational maps in algebraic geometry, which are also not quite defined everywhere. A more concrete but less intuitive definition of a vertex algebra is that it consists of a space with a countable number of bilinear products satisfying certain rather complicated identities. In the case of the monster vertex algebra $V = \oplus V_n$, this gives bilinear maps from $V_i \times V_j$ to V_k for all integers i, j, k, and the special case of the map from $V_2 \times V_2$ to V_2 is (essentially) the Griess product. So the Griess algebra is a sort of section of the monster vertex algebra.

Following an idea of Frenkel, the monster vertex algebra can be used to construct the monster Lie algebra by using the Goddard-Thorn no-ghost theorem from string theory.

This is a $\mathbf{Z}^2$-graded Lie algebra, whose piece of degree $(m,n) \in \mathbf{Z}^2$ has dimension $c(mn)$ whenever $(m,n) \neq (0,0)$. The monster should be thought of as a group of "diagram automorphisms" of this Lie algebra, in the same way that the symmetric group S_3 is a group of diagram automorphisms of the Lie algebra D_4. The monster Lie algebra has a denominator formula, similar to the Weyl denominator formula for finite dimensional Lie algebras and the Macdonald-Kac identities for affine Lie algebras, which looks like

$$j(\sigma) - j(\tau) = p^{-1} \prod_{\substack{m>0 \\ n\in\mathbf{Z}}} (1 - p^m q^n)^{c(mn)}$$

where $p = e^{2\pi i\sigma}$, $q = e^{2\pi i\tau}$. This formula was discovered independently in the 1980's by several people, including Koike, Norton, and Zagier. There are similar identities with $j(\tau)$ replaced by the McKay-Thompson series of any element of the monster, and Cummins and Gannon showed that any function satisfying such identities is a Hauptmodul. So this provides some sort of explanation of Conway and Norton's observation that the McKay-Thompson series are all Hauptmoduls.

So the question "What is the monster" now has several reasonable answers:

1 The monster is the largest sporadic simple group, or alternatively the unique simple group with its order.
2 It is the automorphism group of the Griess algebra.
3 It is the automorphism group of the monster vertex algebra. (This is probably the best answer.)
4 It is a group of diagram automorphisms of the monster Lie algebra.

Unfortunately none of these definitions is completely satisfactory. At the moment all constructions of the algebraic structures above seem artificial; they are constructed as sums of two or more apparently unrelated spaces, and it takes a lot of effort to define the algebraic structure on the sum of these spaces and to check that the monster acts on the resulting structure.

The j-Function and the Monster

Asa Scherer

August 16, 2010

Chapter 1

Introduction

In a set of Hauptmoduls lived a function by the name of Jay. The year was 1979. Jay was quite old, though whether he was 100 or had lived forever was a matter only mathematical philosophers cared about. This particular day, Jay went about his usual business of generating other modular functions. Jay had always been connected to many of his mathematical-object friends. Little did anyone know, Jay held a dark secret. He was also connected... to a Monster.

Now that I have the attention of all my readers aged 5 to 10 and no one else, let's delve into some advanced mathematics!

In this ridiculous introduction, our fellow Jay is standing in for the Klein j-invariant, a complex-valued function that has many fascinating properties, not least of all that any modular function can be written as a rational function of the j-function. The mysterious Monster is the Fischer-Greiss Monster group, the largest of the sporadic simple groups. The real protagonists at the heart of this paper are John Conway and Simon Norton, who formulated the conjecture connecting these two seemingly disparate objects, and Richard Borcherds, who proved [Bor92] their conjecture in 1992.

The first published notion that the j-function was in any way related to the Monster came in 1979, when Conway and Norton noted in [CN79] that each coefficient in the q-expansion of the j-function could be written as a (nontrivial) integral linear combination of the dimensions of irreducible representations of the Monster. For example, the first relevant coefficient, 196884, can be written $196883 + 1$, where 196883 is the dimension of the smallest non-trivial representation of the Monster, and 1 is the dimension of the trivial representation. This observation led to their conjecture, which they titled "monstrous moonshine." This is a rather mysterious and evocative name for a mathematical conjecture, meant to insinuate that it is "distilling information illegally" [Gan04] from the Monster. It also evokes a sense of absurdity, that this connection is so far-fetched that it must be just a coincidence. This, of course, is not the case. Monstrous moonshine indeed illustrates a profound relationship between the j-function. In fact, the conjecture goes beyond just the j-function, but the j-function serves as an especially illustrative case of the conjecture.

Before we proceed any further, let us meet our main characters.

1.1 The Monster

Don't let the Monster group's name fool you! It's really quite a friendly group. Unless you're trying to analyze any piece of it, really, in which case it is quite a monster.

Before we define what the monster really is, we recall some group theoretical definitions:

Definition 1.1.1. *A* **simple group** G *is a group with no nontrivial normal subgroups.*

Normal subgroups, of course, are subgroups H where $ghg^{-1} \in H$ for all $g \in G$ and for all $h \in H$. By nontrivial we mean subgroups that are not the whole group or the trivial subgroup.

Simple groups are important to the study of groups, as any finite group can be decomposed into a composition series:

Definition 1.1.2. *A* **composition series** *is an inclusion chain of normal subgroups*

$$1 = H_0 \triangleleft H_1 \triangleleft H_2 \triangleleft H_3 \triangleleft \cdots \triangleleft G,$$

where H_{i+1}/H_i *is simple for all* $i \geq 1$.

The Jordan-Holder theorem states that any such series is unique up to permutation and isomorphism. So, in essence, simple groups can be considered the "building blocks" of all finite groups, analogous to prime numbers in number theory.

The classification of all finite simple groups was a massive undertaking, only completed in 1983 [Sol01]. The results of this achievement give us the following complete list of finite simple groups:

Infinite families:

1. The cyclic groups $\mathbb{Z}/p\mathbb{Z}$, p prime
2. The alternating groups A_n, $n \geq 5$
3. 16 infinite families of Lie type.

The rest of the simple groups are:

4. Exactly 26 so-called "sporadic" groups.

The **Monster group** $\mathbb{M}$ is the largest of these sporadic simple groups, with group order

$$|\mathbb{M}| = 2^{45} \cdot 3^{20} \cdot 5^{9} \cdot 7^{6} \cdot 11^{2} \cdot 13^{3} \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71 \text{[Gan04]}.$$

So... It's huge. And yet not one of its many nontrivial subgroups is normal.

The Monster was postulated to exist in 1973 by Bernd Fischer and Robert Griess, though it was not explicitly constructed until 1980, when Griess constructed it as the group of automorphisms of a particular 196883-dimensional algebra. The Monster has since been built using other methods. [Gan04] The Monster is a very complicated group, having 194 conjugacy classes, and it contains 19 of the other sporadic simple groups as subgroups or quotients of subgroups, which include the adorably-named Baby Monster. (See [Gan04] and [Sol01] for more information.)

1.2 The j-function

Definition 1.2.1. *The j-function is a complex-valued function defined on all $\tau \in \mathbb{C}$ such that*

$$j(\tau) = 1728 \cdot \frac{g_2(\tau)^3}{g_2(\tau)^3 - 27g_3(\tau)^2},$$

where $g_2(\tau)$ and $g_3(\tau)$ are certain infinite sums over all the points in a particular lattice, as defined in Section 2.4.

Jay has many guises, though! Setting $q = e^{2\pi i\tau}$, we can write

$$j(\tau) = \frac{1}{q} + 744 + 196884q + 21493760q^2 + 864299970q^3 + \cdots := \frac{1}{q} + \sum_{n=0}^{\infty} c(n)q^n,$$

as seen in [Gan04]. This expression is called the *q-expansion* of j, and it is in these integer coefficients that we find the fascinating connection with the Monster. For instance, Conway and Norton's original paper presenting monstrous moonshine [CN79] noted that

$$\begin{aligned} 196884 &= 196883 + 1 \\ 21493760 &= 21296876 + 196883 \\ 864299970 &= 842609326 + 2 \cdot 21296876 + 2 \cdot 196883 + 2 \cdot 1, \end{aligned}$$

where the numbers on the right are dimensions of irreducible representations of the Monster. (We define representations in Section 2.1.)

The j-function has quite a few rather remarkable properties on its own, some of which we will explore in Chapter 3. Namely, we will focus on proving two main theorems. First, though, some more definitions are in order:

Definition 1.2.2. *The group $SL_2(\mathbb{Z})$ is defined as the multiplicative group of all two-by-two matrices with integer entries and determinant 1; that is,*

$$SL_2(\mathbb{Z}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : a, b, c, d \in \mathbb{Z}, \det \begin{pmatrix} a & b \\ c & d \end{pmatrix} = 1 \right\}.$$

Definition 1.2.3. *We write $SL_2(\mathbb{Z})\backslash\mathbb{H}$ to denote the quotient of the upper half-plane $\mathbb{H}$ by the action of $SL_2(\mathbb{Z})$ on $\mathbb{H}$ (which will be defined in Chapter 2).*

We have two main goals in this paper. First, we will focus on proving the following properties of $j(\tau)$:

Theorem 1.2.4. *The j-function is a bijection between $SL_2(\mathbb{Z})\backslash\mathbb{H}$ and $\mathbb{C}$.*

Theorem 1.2.5. *Every modular function is a rational function of $j(\tau)$.*

Secondly, we will give the reader context and understanding of the actual statement of monstrous moonshine. We will first establish some context for these theorems by presenting some preliminary material in Chapter 2, including a brief introduction to representation theory, lattices, and modular forms. Chapter 3, following the logical flow laid out in [Cox89], covers the proof of our two main theorems, Theorems 1.2.4 and 1.2.5, and an additional property of $j(\tau)$ [Bor92] regarding the denominator formula. Chapter 4 defines the moonshine module, necessary to understand monstrous moonshine, and then states Borcherds' theorem, concluding by touching on a few of the related areas of moonshine research beyond the original conjecture.

A brief note: This paper assumes the reader to have a basic knowledge of group theory and complex analysis, but in general, we will be fairly explicit in defining our terms; many of these will be covered in Chapter Two.

Chapter 2

Preliminaries

Treat this chapter as a sort of smorgasbord of mathematical theory; a sampling of the delicious tools needed to understand the j-function and its Monstrous connection. We begin with an appetizer of Representation Theory, follow with a salad of Lattice, and finish with a Modular Function main course.

2.1 Representation Theory

Linear algebra is an incredibly useful tool, finding applications scattered throughout various mathematical and scientific disciplines. The beauty of linear algebra is that once we associate some sort of mathematical object to a matrix, we can instantly make many observations about the matrix, which then may apply to the original object. Group theorists in particular use linear algebra to simplify certain tasks of group structure analysis using maps called *representations*. In this section, we review some basic facts about representations of finite groups over $\mathbb{C}$. For more information, see [FH91].

Definition 2.1.1. *Given a finite group G, a* **representation of G on a vector space V over $\mathbb{C}$** *is a map ρ from G to the group of linear automorphisms of V, $GL(V)$, such that $\rho(g_1g_2) = \rho(g_1) \circ \rho(g_2)$.*

So, essentially, a representation transfers group properties into a linear algebraic context, where our linear transformations behave as their preimage group elements do. A note: We frequently refer to V itself as the representation, rather than the map ρ. Since our representations are vector spaces, we can certainly consider subspaces that are also representations.

Definition 2.1.2. *Let vector space V be a representation of group G. Let W be a subspace of V. If $\rho(g)(\mathbf{v}) \in W$ for all $\mathbf{v} \in W$, then we call W a* **subrepresentation** *of V with respect to G.*

As we have introduced the concept of subrepresentation, we wish to now define the most "basic" type of representation:

Definition 2.1.3. *An* **irreducible representation for** G *is a representation V that cannot be expressed as a direct sum of subrepresentations.*

In fact, we get a stronger result telling us that irreducible representations are our "representation building blocks":

Theorem 2.1.4. *For any representation V of G, we can express V as a unique direct sum of irreducible representations [FH91].*

Remark: Recall that if $A = (a_{ij})$ is a complex $n \times n$ matrix, then the trace of A is given by $\operatorname{tr}(A) = \sum_{i=1}^{n} a_{ii}$, the sum of the diagonal entries in A.

Let $g \in G$. Then, if ρ is a representation for G on V, $\rho(g)$ is a linear transformation from V to itself. But, we know from linear algebra that any linear transformation can be expressed as a matrix, considering some standard, ordered arrangement of basis vectors. Hence we can talk about the trace of $\rho(g)$'s associated matrix. It is easily shown that this number is independent of choice of basis for V, which leads us to the following definition.

Definition 2.1.5. *Let $g \in G$, and let ρ be a representation for G on V. Let M_g be the matrix with respect to some ordered basis corresponding to $\rho(g)$. Then the trace of M_g is called the* **character of g with respect to the representation** *V, frequently denoted $\chi_V(g)$.*

Note that the character of the identity element $e \in G$ with respect to a representation V is always equal to the dimension of V, call it n, since $\rho(e)$ is the identity transformation, and thus its associated $n \times n$ matrix is just I_n, the $n \times n$ identity matrix. To get a better feel for what a representation really is, we present a brief example.

Example.

Let $G = S_3$ be the symmetric group of order 3, that is, the group of permutations of three elements. Let W be the vector space over $\mathbb{C}$ generated by the basis

$$B = \{(1,0,0), (0,1,0), (0,0,1)\}.$$

That is, $W = \mathbb{C}^3$. Define the representation map ρ like so: $\rho(g) = T_g$, where T_g is defined by

$$T_g(z_1, z_2, z_3) = (z_{g^{-1}(1)}, z_{g^{-1}(2)}, z_{g^{-1}(3)}),$$

where $g^{-1}(n)$ denotes the number (1, 2, or 3) that is sent to position n by the permutation g. Let's pick a specific g: Say, $g = (12)$, that is, the transposition that sends 1 to 2, 2 to 1, and 3 to itself. Then we can note where $\rho(g) = T_g$ sends our basis elements:

$$T_g(1,0,0) = (0,1,0)$$
$$T_g(0,1,0) = (1,0,0)$$
$$T_g(0,0,1) = (0,0,1)$$

Hence our matrix associated with T_g (with respect to our given ordered basis) is

$$M_g := \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Thus, the character of g with respect to representation W is

$$\mathrm{Tr}(M_g) = 0 + 0 + 1 = 1.$$

Note that any other permutation of order 2 in S_3 will also have character 1, and that any permutation of order 3 has a character of 0 (since none of the elements are fixed.) The identity element, of course, has character 3 as expected, since $dim(W) = 3$.

In fact, these observations can be correctly generalized by the following statement:

Theorem 2.1.6. *With respect to a given representation V of group G, any two elements of the same conjugacy class of G have the same character. [FH91]*

Remark: Thus, if we are interested in finding every group element's character, we only need to pick one representative from each conjugacy class. In fact, we have a further correlation between conjugacy classes and representations: The number of irreducible representations of a group G is equal to the number of congruence classes of G. [FH91]

Continuing our example, it turns out that our representation $W = \mathbb{C}^3$ is not actually irreducible, and can be expressed as the direct sum of a 1-dimensional and a 2-dimensional vector space. In particular, we can write $W = U \oplus V$, where $U = \mathrm{span}\{(1,1,1)\}$, and $V = \{(z_1, z_2, z_3) | z_1 + z_2 + z_3 = 0\}$. U is clearly irreducible, since it has dimension 1, and in fact V is irreducible, too [FH91]. Thus the direct sum $U \oplus V$ is the unique decomposition of $W = \mathbb{C}^3$ into irreducible representations of S_3.

2.2 Lattices

A **lattice** L is an additive subgroup of $\mathbb{C}$ generated by two $\mathbb{R}$-linearly independent complex numbers ω_1 and ω_2. That is, $L = \{m\omega_1 + n\omega_2 : m, n \in \mathbb{Z}\}$, with $\frac{\omega_1}{\omega_2} \notin \mathbb{R}$. This last requirement gives us the desired linear independence of ω_1 and ω_2. Geometrically, it is equivalent to saying that the two points do not lie on the same vector beginning at the origin, when viewing the complex plane as analogous to $\mathbb{R}^2$. Notationally, we write

$$L = [\omega_1, \omega_2] = \{m\omega_1 + n\omega_2 : m, n \in \mathbb{Z}\}.$$

Visually, lattices create nice parallelogram-tilings of $\mathbb{C}$. Two different lattices can be related in a particular way:

Definition 2.2.1. *The lattices $L = [\omega_1, \omega_2]$ and $L' = [\omega_1', \omega_2']$ are said to be* **homothetic** *if there exists $\lambda \in \mathbb{C}$ such that $L' = \lambda L$. That is, $[\omega_1', \omega_2'] = [\lambda\omega_1, \lambda\omega_2]$.*

Note that this property, homothety, defines an equivalence class on the set of all complex lattices; that is, we can look at the collection of all possible complex lattices and partition them by which lattices are homothetic to one another. We will call these equivalence classes **homothety classes**.

Now that we have lattices, we can define some important pieces of the j-function.

Definition 2.2.2. *Let $n \geq 3$, and let L be a lattice. Then*

$$G_n(L) = \sum_{\omega \in L \setminus \{0\}} \frac{1}{\omega^n}$$

is called the **Eisenstein series of order n for L.**

You may now be asking, "What, if any, n do we know this expression to converge for?" Well, that's a good question, hypothetical reader, one which we will now answer:

Lemma 2.2.3. *Suppose L is a lattice and $s \in \mathbb{R}$ with $s > 2$. Then the series*

$$G_s(L) = \sum_{\omega \in L \setminus \{0\}} \frac{1}{\omega^s}$$

converges absolutely.

Proof. Let ω_1, $\omega_2 \in \mathbb{C}$ be the generators of L, that is, $L = [\omega_1, \omega_2]$. So then we need to show that

$$\sum_{\omega \in L \setminus \{0\}} \frac{1}{|\omega|^s} = \sum_{m,n} \frac{1}{|m\omega_1 + n\omega_2|^s}$$

converges, where the expression on the right is a sum over all integer pairs $(m, n) \neq (0, 0)$.

Define

$$M = \min\{|x\omega_1 + y\omega_2| : x^2 + y^2 = 1\}.$$

Let x and y be real numbers such that at least one of x and y is nonzero. Note that

$$\left(\frac{x}{\sqrt{x^2+y^2}}\right)^2 + \left(\frac{y}{\sqrt{x^2+y^2}}\right)^2 = \frac{x^2+y^2}{x^2+y^2} = 1.$$

Hence, by the definition of M,

$$\left|\frac{x}{\sqrt{x^2+y^2}}\omega_1 + \frac{y}{\sqrt{x^2+y^2}}\omega_2\right| = \frac{|x\omega_1 + y\omega_1|}{\sqrt{x^2+y^2}} \geq M,$$

and so

$$|x\omega_1 + y\omega_2| \geq M\sqrt{x^2+y^2}$$

for all $x, y \in \mathbb{R}$.

We picked x and y so that at least one of them was nonzero to avoid having a zero denominator in our earlier expression, but this inequality is clearly true for $x = y = 0$, so it holds for all $x, y \in \mathbb{R}$.

But then

$$\sum_{m,n} \frac{1}{|m\omega_1 + n\omega_2|^s} \leq \frac{1}{M^s} \sum_{m,n} \frac{1}{(m^2+n^2)^{s/2}}.$$

Consider, then, the integral

$$\iint\limits_{x^2+y^2 \geq 1} \frac{1}{(x^2+y^2)^{s/2}} dx\ dy.$$

If this integral converges, we are done. Rewriting in terms of traditional polar coordinates r and θ, we have

$$\int\limits_{r=1}^{\infty}\int\limits_{\theta=0}^{2\pi}\frac{1}{r^s}r\,d\theta\,dr=\int\limits_{r=1}^{\infty}\int\limits_{\theta=0}^{2\pi}\frac{1}{r^{s-1}}d\theta\,dr.$$

Evaluating this expression with rudimentary calculus, we get

$$\int\limits_{r=1}^{\infty}\frac{2\pi}{r^{s-1}}dr.$$

Since $s>2$, then $s-1>1$, and so this integral exists and is a finite number. It follows that

$$\sum_{m,n}\frac{1}{|m\omega_1+n\omega_2|^s}$$

must converge.

$\square$

Hence, any Eisenstein series of order greater than 2 converges absolutely. Two particularly important Eisenstein series that we are especially interested in are

$$g_2(L)=60G_4(L)=60\sum_{\omega\in L\setminus\{0\}}\frac{1}{\omega^4}$$

and

$$g_3(L)=140G_6(L)=140\sum_{\omega\in L\setminus\{0\}}\frac{1}{\omega^6}.$$

We introduce now an important lattice-based function that will play a part in the proofs in Chapter 3.

Definition 2.2.4. *The* **Weierstrass $\wp$-function** *is defined by the following:*

$$\wp(z;L)=\frac{1}{z^2}+\sum_{\omega\in L\setminus\{0\}}\left(\frac{1}{(z-\omega)^2}-\frac{1}{\omega^2}\right)$$

for $z\in\mathbb{C}$ and L a lattice, where the sum on the right is a sum over all nonzero lattice points ω of L.

If it is clear (or doesn't matter) which lattice we are referring to, $\wp(z;L)$ can be abbreviated to simply $\wp(z)$. The following lemmas about the $\wp$-function can be found in [Cox89]:

Lemma 2.2.5. *The set of singularities of $\wp(z;L)$ is exactly equal to the set of lattice points in L.*

This lemma becomes fairly clear intuitively by looking at the denominator terms in $\wp(z;L)$.

Lemma 2.2.6. *The Laurent expansion of $\wp(z)$ for the lattice L takes the form*

$$\wp(z) = \frac{1}{z^2} + \sum_{n=1}^{\infty} p(g_2(L), g_3(L))z^{2n},$$

where $p(g_2(L), g_3(L))$ is a polynomial with rational coefficients, independent of L, in $g_2(L)$ and $g_3(L)$.

Proofs of these lemmas can be found in [Cox89]. Another function, which turns out to be an important piece of the j-function, is called the discriminant of the lattice L.

Definition 2.2.7. *The discriminant of the lattice L, denoted $\Delta(L)$, is given by*

$$\Delta(L) = g_2(L)^3 - 27g_3(L)^2.$$

Remark: As it just so happens, $\Delta(L)$ is the discriminant of the polynomial $p(x) = 4x^3 - g_2x - g_3$, which, incidentally, the Weirstrauss $\wp$-function satisfies like so, as mentioned by [Cox89]:

$$\wp'(z)^2 = 4\wp(z)^3 - g_2\wp(z) - g_3.$$

The roots of this polynomial $p(x)$ are $e_1 = \wp(\omega_1/2)$, $e_2 = \wp(\omega_2/2)$, and $e_3 = \wp(\frac{\omega_1+\omega_2}{2})$. In fact, these roots are distinct [Apo90]. Hence, since the discriminant of a polynomial is a product of differences of its roots, we get the following lemma:

Lemma 2.2.8. *For any lattice L, the discriminant $\Delta(L)$ is nonzero.*

2.3 Modular Functions

Modular functions: Is there anything more beautiful? Probably, but that won't stop this mathematician from waxing hyperbolic! But before we get to these awe-inspiring paragons of beauty, we must first introduce some context.

$\mathrm{SL}_2(\mathbb{Z})$, as noted before, is defined as the group, under multiplication, of 2×2 matrices with integer entries and determinant 1. In the context of modular functions, we call the group $\mathrm{SL}_2(\mathbb{Z})$ the **modular group** Γ. It turns out that $\mathrm{SL}_2(\mathbb{Z})$ acts on the upper half-plane $\mathbb{H} = \{a + bi \in \mathbb{C} : b > 0\}$ through linear fractional transformations like so:

If $\tau \in \mathbb{H}$ and $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, then

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot \tau = \frac{a\tau + b}{c\tau + d}.$$

An easy calculation shows that the action of $\mathrm{SL}_2(\mathbb{Z})$ takes elements of $\mathbb{H}$ to $\mathbb{H}$. We have a nice property of $\mathrm{SL}_2(\mathbb{Z})$ in that it is generated by two matrices: [Apo90]

$$T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \qquad \text{and} \qquad S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Note that

$$T \cdot \tau = \tau + 1 \quad \text{and} \quad S \cdot \tau = -\frac{1}{\tau}.$$

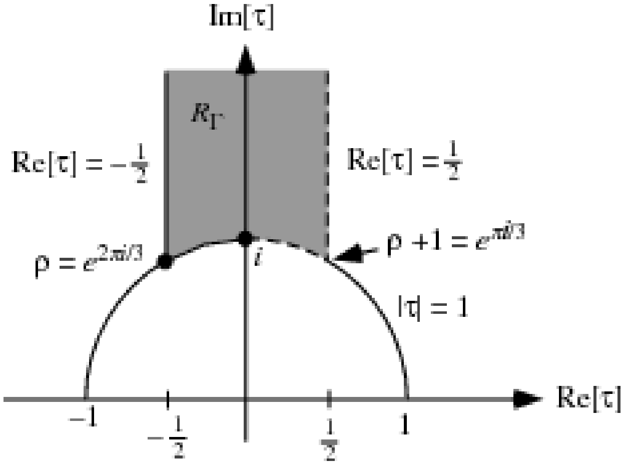

Figure 2.1: The Fundamental region F, here denoted R_Γ[BB87].

As we will see, modular forms have the property that they are invariant under $\mathrm{SL}_2(\mathbb{Z})$. Hence, we wish to analyze which points in $\mathbb{H}$ are "$\mathrm{SL}_2(\mathbb{Z})$-equivalent," that is, when two points $\tau, \tau' \in \mathbb{H}$ are such that $\tau' = \gamma \cdot \tau$ for some $\gamma \in \mathrm{SL}_2(\mathbb{Z})$. Specifically, is there a nice subregion of $\mathbb{H}$ where every point is $\mathrm{SL}_2(\mathbb{Z})$-distinct to every other point in the region and every $\mathrm{SL}_2(\mathbb{Z})$ equivalence class is represented? Why, yes! Yes, there is. This region is

$$F = \left\{ z \in \mathbb{C} : |z| > 1, -\frac{1}{2} \leq Re(z) < \frac{1}{2} \right\} \cup \left\{ z \in \mathbb{C} : |z| = 1, -\frac{1}{2} \leq Re(z) \leq 0 \right\},$$

and is called a fundamental region of the modular group Γ (see Figure 2.3).
F has the following properties:

1. Any two distinct points in F are not $\mathrm{SL}_2(\mathbb{Z})$-equivalent.
2. For any $\tau \in \mathbb{H}$, there is a point τ' in F such that τ and τ' are $\mathrm{SL}_2(\mathbb{Z})$-equivalent.

So, basically, whenever we're dealing with $\mathrm{SL}_2(\mathbb{Z})$-invariance of some kind, we can restrict our analysis to F. A side note: The generating matrices S and T transform F in predictable and visually lovely ways (see Figure 2.2). We now define modular functions.

Definition 2.3.1. *A function $f : \mathbb{H} \to \mathbb{C}$ is called a* **modular function** *if it satisfies the following:*

1. *f is meromorphic in the upper half-plane $\mathbb{H}$.*
2. *$f(\gamma \cdot \tau) = \tau$ for any $\gamma \in SL_2(\mathbb{Z})$ and all $\tau \in \mathbb{H}$.*
3. *The function f has a Fourier expansion at $i\infty$ of the form*

$$f(\tau) = \sum_{n=-m}^{\infty} a(n) q^n,$$

where $q = e^{2\pi i \tau}$, and m is some integer.

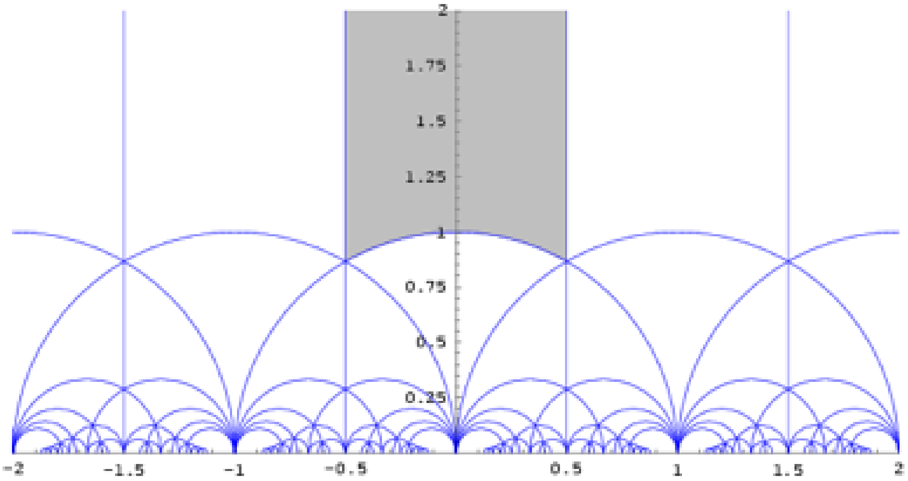

Figure 2.2: Each region bounded by the circles and lines of this figure represent a fundamental region for Γ, reached by transforming F via some combination of matrices S and T. [Arm]

Property 2 gives us modularity; that is, f is invariant under the action of $\mathrm{SL}_2(\mathbb{Z})$. Some notes on Property 3: First of all, when considering the behavior of f at infinity, we mean $i\infty$. The reason for this is due to the $\mathrm{SL}_2(\mathbb{Z})$-invariance of f; moving toward z-values with real part approaching ∞, the function values just keep cycling through the same values – picture moving your input points to the left through the Fundamental Domain F.

Secondly, this Fourier expansion in property 3 is called the **q-expansion of** f and can be thought of as the Fourier expansion at $i\infty$, since $\lim_{\tau \to i\infty} e^{2\pi i \tau} = 0$. If $m > 0$, then f has a pole of order m at $i\infty$. If $m \leq 0$, then f is analytic at $i\infty$. Another way of stating property 3 is that f is **meromorphic at the cusp** or **meromorphic at** ∞.

Remark: Modular functions are a specific case of a more general type of function called a modular form. Basically, a modular form is like a modular function but with a slightly modified notion of $\mathrm{SL}_2(\mathbb{Z})$-invariance. More precisely, a **modular form** $f(\tau)$ **of weight** k is a function, either meromorphic or holomorphic on $\mathbb{H}$, that has Property 3 of Definition 2.3.1, and $f(\gamma \cdot \tau) = (c\tau + d)^k f(\tau)$, where $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. In particular, a modular function is a modular form of weight 0.

It turns out that holomorphic modular forms of weight k form a finite dimensional vector space M_k, with a basis given by certain products of G_4 and G_6. Hence we can consider certain linear operators that map M_k to M_k. One such operator, which we will need in a later proof, is called a Hecke operator. The following definition and lemma can be found in [Apo90].

Definition 2.3.2. *For a fixed integer k and any $n \in \mathbb{N}$, the n***th Hecke operator** T_n *is defined on M_k by*

$$(T_n f)(\tau) = n^{k-1} \sum_{d \mid n} d^{-k} \sum_{b=0}^{d-1} f\left(\frac{n\tau + bd}{d^2}\right).$$

What we are really interested in, though, is the Fourier expansion of such Hecke-operated functions:

Lemma 2.3.3. *If $f \in M_k$ and f has the Fourier expansion*

$$f(\tau) = \sum_{m=0}^{\infty} c(m) q^m,$$

then $T_n f$ has the Fourier expansion

$$(T_n f)(\tau) = \sum_{m=0}^{\infty} \left(\sum_{d|(m,n)} d^{k-1} c\left(\frac{mn}{d^2}\right) \right) q^m.$$

Thus if our function f is a modular function; that is, an element of M_0, this expansion becomes

$$(T_n f)(\tau) = \sum_{m=0}^{\infty} \left(\sum_{d|(m,n)} \frac{1}{d} \cdot c\left(\frac{mn}{d^2}\right) \right) q^m .$$

Further exploration of modular functions can be found in [Apo90] and [Ser73].

2.4 Jay at Last!

Now we finally have the tools to define the j-function. Let's do so!

Definition 2.4.1. *The j-invariant of a lattice L is defined as the complex number*

$$j(L) = 1728 \cdot \frac{g_2(L)^3}{g_2(L)^3 - 27 g_3(L)^2},$$

where g_2 and g_3 are the previously-defined modified Eisenstein series.

Note that the denominator of j is $g_2(L)^3 - 27g_3(L)^2 = \Delta(L)$. This is handy, since Lemma 2.2.8 tells us that $\Delta(L)$ is never 0 for any lattice L. The j-function itself is defined like so:

Definition 2.4.2. *The j-**function** $j(\tau)$ is defined as a complex-valued function such that, for any $\tau \in \mathbb{H}$,*

$$j(\tau) = j([1, \tau]),$$

that is, $j(\tau)$ is the j-invariant of the lattice $[1, \tau]$.

Similarly, we modify our old series g_2 and g_3 so that

$$g_2(\tau) = g_2([1, \tau]) = 60 \sum_{m,n} \frac{1}{(m + n\tau)^4}$$

and

$$g_3(\tau) = g_3([1, \tau]) = 140 \sum_{m,n} \frac{1}{(m + n\tau)^6}.$$

So then we have that

$$j(\tau) = 1728 \cdot \frac{g_2(\tau)^3}{g_2(\tau)^3 - 27 g_3(\tau)^2}.$$

The j-function has many important properties, such as the following:

Lemma 2.4.3. *The j-function is holomorphic on the upper half plane $\mathbb{H}$.*

We will use this lemma as a fact. A good proof, relying on the uniform convergence of g_2 and g_3 can be found in [Cox89].

Chapter 3

Properties of $j(\tau)$

3.1 Proof of Theorem 1.2.4

Recall that Theorem 1.2.4 states that $j(\tau)$ is a bijection between $\mathrm{SL}_2(\mathbb{Z})\backslash\mathbb{H}$ and $\mathbb{C}$. Our first step is to show that $j(L)$, as an invariant, characterizes a lattice L with respect to its homothetic lattices. (Recall the definition of *homothetic*, Definition 2.2.1.)

Theorem 3.1.1. *If L and L' are lattices in $\mathbb{C}$, then $j(L) = j(L')$ if and only if L and L' are homothetic.*

Proof. ($\Leftarrow$) Suppose L and L' are homothetic; that is, $L' = \lambda L$ for some $\lambda \in \mathbb{C}$. We know

$$g_2(L') = g_2(\lambda L) = 60 \sum_{\omega \in L\backslash\{0\}} \frac{1}{(\lambda\omega)^4} = \frac{1}{\lambda^4} 60 \sum_{\omega \in L\backslash\{0\}} \frac{1}{\omega^4} = \lambda^{-4} g_2(L).$$

Similarly,

$$g_3(L') = g_3(\lambda L) = 140 \sum_{\omega \in L\backslash\{0\}} \frac{1}{(\lambda\omega)^6} = \frac{1}{\lambda^6} 140 \sum_{\omega \in L\backslash\{0\}} \frac{1}{\omega^6} = \lambda^{-6} g_3(L).$$

So then

$$j(L') = 1728 \cdot \frac{g_2(L')^3}{g_2(L')^3 - 27 g_3(L')^2} = 1728 \cdot \frac{\lambda^{-12} g_2(L)^3}{\lambda^{-12} g_2(L)^3 - 27\lambda^{-12} g_3(L)^2}$$
$$= 1728 \cdot \frac{g_2(L)^3}{g_2(L)^3 - 27 g_3(L)^2} = j(L).$$

□

Now we prove the reverse implication.
($\Rightarrow$) Let $j(L) = j(L')$. Suppose we can find a $\lambda \in \mathbb{C}$ such that $g_2(L') = \lambda^{-4} g_2(L)$ and $g_3(L') = \lambda^{-6} g_3(L)$. Then $g_2(L') = g_2(\lambda L)$ and $g_3(L) = g_3(\lambda L)$, and by Lemma 2.2.6, we have that the Laurent expansion for $\wp(z; L')$ is

$$\wp(z; L') = \frac{1}{z^2} + \sum_{n=1}^{\infty} p(g_2(L'), g_3(L')) z^{2n} = \frac{1}{z^2} + \sum_{n=1}^{\infty} p(g_2(\lambda L), g_3(\lambda L)) z^{2n} = \wp(z; \lambda L).$$

Thus $\wp(z; L')$ and $\wp(z; \lambda L)$ have the same Laurent expansion about 0. So then these two functions agree on a neighborhood U about the origin. But we have that $\wp(z; L')$ and $\wp(z; \lambda L)$ are analytic on the region $\Omega := \mathbb{C} \setminus (\lambda L \cup L')$, and the set

$$\{z \in \Omega : \wp(z; L') = \wp(z; \lambda L)\}$$

certainly has a limit point in $U \cap \Omega$, and hence

$$\wp(z; L') = \wp(z; \lambda L)$$

on all of Ω, so $\wp(z; L')$ and $\wp(z; \lambda L)$ must have the same poles. Since, by Lemma 2.2.5, the lattice L' is precisely the set of poles of $\wp(z; L')$, then $L' = \lambda L$. Thus, to complete this proof, we need only find a $\lambda \in \mathbb{C}$ such that $g_2(L') = \lambda^{-4} g_2(L)$ and $g_3(L') = \lambda^{-6} g_3(L)$.

Note that

$$g_2(L)^3 - 27 g_3(L)^2 = \Delta(L)$$

can never be 0 by Lemma 2.2.8. Thus, we have the following three cases:

- Case 1: $g_2(L') = 0$ and $g_3(L') \neq 0$. Then choose λ so that $\lambda^6 = \frac{g_3(L)}{g_3(L')}$.
- Case 2: $g_3(L') = 0$ and $g_2(L') \neq 0$. Then choose λ so that $\lambda^4 = \frac{g_2(L)}{g_2(L')}$.
- Case 3: $g_2(L') \neq 0$ and $g_3(L') \neq 0$. Then choose λ such that $\lambda^4 = \frac{g_2(L)}{g_2(L')}$. Since we have that $j(L) = j(L')$, then

$$1728 \cdot \frac{g_2(L)^3}{g_2(L)^3 - 27 g_3(L)^2} = 1728 \cdot \frac{g_2(L')^3}{g_2(L')^3 - 27 g_3(L')^2}.$$

By substituting $\lambda^4 g_2(L')$ for $g_2(L)$, we get that

$$\frac{(\lambda^4 g_2(L'))^3}{(\lambda^4 g_2(L'))^3 - 27 g_3(L)^2} = \frac{g_2(L')^3}{g_2(L')^3 - 27 g_3(L')^2}.$$

Cross-multiplying and solving for λ^{12} yields that

$$\lambda^{12} = \frac{-27 g_3(L)^2}{-27 g_3(L')^2} = \frac{g_3(L)^2}{g_3(L')^2}.$$

So then

$$\lambda^6 = \pm \frac{g_3(L)}{g_3(L')}.$$

Assume the sign on the right is +, since if not, we can replace λ by $i\lambda$. Thus we have that $g_3(L') = \lambda^{-6} g_3(L)$.

Hence, in any of the cases, we can find a $\lambda \in \mathbb{C}$ such that $g_2(L') = \lambda^{-4} g_2(L)$ and $g_3(L') = \lambda^{-6} g_3(L)$.

□

Remark: We just showed that the j-invariant characterizes lattice homothety classes. Now, given some lattice $L = [\omega_1, \omega_2]$, there is a homothetic lattice $L' = [1, \frac{\omega_2}{\omega_1}]$ (by letting $\lambda = \frac{1}{\omega_1}$, renumbering if necessary so that $\frac{\omega_2}{\omega_1} \in \mathbb{H}$). But then, by Theorem 3.1.1 and Definition 2.4.2,

$$j(L) = j(L') = j\left(\frac{\omega_2}{\omega_1}\right)$$

. Hence the j-function in a sense represents all possible lattice homothety classes.

Theorem 3.1.1 leads directly to a very nice property of the j-function: invariance under the action of $\mathrm{SL}_2(\mathbb{Z})$.

Theorem 3.1.2. *If $\tau, \tau' \in \mathfrak{h}$, then $j(\tau) = j(\tau')$ if and only if $\tau' = \gamma\tau$ for some $\gamma \in SL_2(\mathbb{Z})$. In particular, $j(\tau)$ is $SL_2(\mathbb{Z})$-invariant.*

Proof. ($\Rightarrow$) Suppose $j(\tau) = j(\tau')$. By definition of the j-function, and by Theorem 3.1.1, then the lattices $L := [1, \tau]$ and $L' := [1, \tau']$ are homothetic. That is, $[1, \tau'] = [\lambda, \lambda\tau]$ for some $\lambda \in \mathbb{C}$.

Hence, we can write

$$\lambda = r\tau' + s \text{ and } \lambda\tau = p\tau' + q,$$

with $p, q, r, s \in \mathbb{Z}$. We then have that

$$\tau = \frac{\lambda\tau}{\lambda} = \frac{p\tau' + q}{r\tau' + s} = \begin{pmatrix} p & q \\ r & s \end{pmatrix} \cdot \tau'.$$

Thus we just need to show that $\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$.

We have that

$$\begin{pmatrix} p & q \\ r & s \end{pmatrix} \begin{pmatrix} \tau' \\ 1 \end{pmatrix} = \begin{pmatrix} \lambda\tau \\ \lambda \end{pmatrix}.$$

Similarly, since $[1, \tau'] = [\lambda, \lambda\tau]$, there exists a matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with integer entries such that

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \lambda\tau \\ \lambda \end{pmatrix} = \begin{pmatrix} \tau' \\ 1 \end{pmatrix}.$$

But then

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} p & q \\ r & s \end{pmatrix} \begin{pmatrix} \tau' \\ 1 \end{pmatrix} = \begin{pmatrix} \tau' \\ 1 \end{pmatrix}.$$

Define the matrix

$$A := \begin{pmatrix} a' & b' \\ c' & d' \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} p & q \\ r & s \end{pmatrix}.$$

So $A \left(\begin{smallmatrix} \tau' \\ 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} \tau' \\ 1 \end{smallmatrix}\right)$. Hence $a'\tau' + b' = \tau'$. Divide through by τ' and we get that $a' + b'\frac{1}{\tau'} = 1$. But $\frac{1}{\tau'} \notin \mathbb{R}$, since $[1, \tau']$ is a lattice. Hence, since a' and b' are integers, $b' = 0$ and $a' = 1$. Similarly, we have that $c'\tau' + d' = 1$, leading to the conclusion that $c' = 0$ and $d' = 1$. Thus we have that $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, and so

$$\det(A) = 1 = \det \begin{pmatrix} a & b \\ c & d \end{pmatrix} \det \begin{pmatrix} p & q \\ r & s \end{pmatrix}.$$

Since the determinants on the right must be integers, then $\det \left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) = \pm 1$. So now we just have to show that $\det \left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) > 0$.

Let $\tau' = a + bi$ for $a, b \in \mathbb{R}$. Then

$$\mathrm{Im}(\tau) = \mathrm{Im}\left(\frac{p\tau' + q}{r\tau' + s}\right) = \frac{b(ps - qr)}{|r\tau + s|^2} = \frac{\mathrm{Im}(\tau')(ps - qr)}{|r\tau + s|^2}.$$

Since τ and τ' are in $\mathbb{H}$, then $ps - qr = \det\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) > 0$, so

$$\det\begin{pmatrix} p & q \\ r & s \end{pmatrix} = 1,$$

and we have that $\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$.

Now we prove the other direction of the implication, which proves to be a bit more straightforward:

($\Leftarrow$) Suppose $\tau' = \gamma\tau$ for some $\gamma \in \mathrm{SL}_2(\mathbb{Z})$. That is,

$$\tau' = \frac{p\tau + q}{r\tau + s},$$

with $p, q, r, s \in \mathbb{Z}$, and $\det\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) = 1$.

Let $\lambda = r\tau + s$. Then we have that

$$\lambda[1, \tau'] = (r\tau + s)\left[1, \frac{p\tau + q}{r\tau + s}\right] = [r\tau + s, p\tau + q].$$

But we can write

$$-q(r\tau + s) + s(p\tau + q) = (ps - qr)\tau + (qs - qs) = \tau,$$

since $\left(\begin{smallmatrix} p & q \\ r & s \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$. Similarly,

$$p(r\tau + s) - r(p\tau + q) = (pr - pr)\tau + (ps - qr) = 1.$$

Thus $[1, \tau] \subseteq \lambda[1, \tau']$, and since clearly $\lambda[1, \tau'] \subseteq [1, \tau]$, we have that

$$[r\tau + s, p\tau + q] = \lambda[1, \tau'] = [1, \tau],$$

and hence $[1, \tau']$ is homothetic to $[1, \tau]$. It follows from Theorem 3.1.1 that $j(\tau) = j(\tau')$. □

Let us now think of Theorem 3.1.2 in the context of Theorem 1.2.4, what we aim to prove. The forward implication of Theorem 3.1.2 gives that $j(\tau)$, viewed as a map from $\mathrm{SL}_2(\mathbb{Z})\backslash\mathbb{H}$ to $\mathbb{C}$, is well-defined. The backwards implication gives us that this map is one-to-one. Hence we already have half of Theorem 1.2.4 proved; namely, that $j(\tau)$ is one-to-one as a map from $\mathrm{SL}_2(\mathbb{Z})\backslash\mathbb{H}$ to $\mathbb{C}$. Now we wish to show surjectivity. First, though, we must examine its behavior at the cusp, $i\infty$.

Lemma 3.1.3. *We have that*

$$\lim_{\mathrm{Im}(\tau)\to\infty} j(\tau) = \infty.$$

Proof. To start, consider

$$g_2(\tau) = 60\sum_{m,n} \frac{1}{(m + n\tau)^4} = 60\left(2\sum_{m=1}^{\infty} \frac{1}{m^4} + \sum_{m,n;n\neq 0} \frac{1}{(m + n\tau)^4}\right). \tag{3.1}$$

Let $\tau = a + bi$. But if we consider a single term in the right-hand sum, we find that

$$\lim_{\operatorname{Im}(\tau)\to\infty} \frac{1}{(m+n\tau)^4} = \lim_{\operatorname{Im}(\tau)\to\infty} \frac{1}{m^4 + 4m^3(n\tau) + 6m^2(n\tau)^2 + 4m(n\tau)^3 + (n\tau)^4}.$$

Because $n \neq 0$, then the b^4 term in $(n\tau)^4 = n^2(a^4 + 4a^3(bi) - 6a^2b^2 + 4a(bi)^3 - b^4)$ dominates the denominator as b becomes arbitrarily large. Hence,

$$\lim_{\operatorname{Im}(\tau)\to\infty} \frac{1}{(m+n\tau)^4} = 0.$$

Since $g_2(\tau)$ is uniformly convergent by Lemma 2.2.3, then, in taking the limit, equation (3.1) becomes

$$\lim_{\operatorname{Im}(\tau)\to\infty} g_2(\tau) = 120 \sum_{m=1}^{\infty} \frac{1}{m^4}.$$

But this is a known infinite sum, with $\sum_{m=1}^{\infty} \frac{1}{m^4} = \frac{\pi^4}{90}$. Hence,

$$\lim_{\operatorname{Im}(\tau)\to\infty} g_2(\tau) = \frac{4}{3}\pi^4.$$

The limit behavior of $g_3(\tau)$ is shown similarly, with the sum $\sum_{m=1}^{\infty} \frac{1}{m^6} = \frac{\pi^6}{945}$ giving us that

$$\lim_{\operatorname{Im}(\tau)\to\infty} g_3(\tau) = \frac{8}{27}\pi^6.$$

Combining these two results, we get the limit of the denominator of the j-function:

$$\lim_{\operatorname{Im}(\tau)\to\infty} \left[g_2(\tau)^3 - 27g_3(\tau)^2\right] = \left(\frac{4}{3}\pi^4\right)^3 - 27\left(\frac{8}{27}\pi^6\right)^2 = 0. \tag{3.2}$$

Thus, it follows that

$$\lim_{\operatorname{Im}(\tau)\to\infty} j(\tau) = \infty.$$

□

Remark: Since, as shown in equation (3.2), $\Delta(\tau)$ has a simple zero at ∞, then $j(\tau)$ has a simple pole at ∞, and hence $j(\tau)$ is meromorphic at ∞. Combining this fact with Theorem 3.1.2, we have the following immediate corollary:

Corollary 3.1.4. *The function $j(\tau)$ is a modular function for $SL_2(\mathbb{Z})$.*

Now we can prove that $j(\tau)$ is, indeed, surjective.

Theorem 3.1.5. *The function $j : \mathbb{H} \to \mathbb{C}$ is surjective.*

Proof. We know that $j(\tau)$ is nonconstant on $\mathbb{H}$, since there are values for τ that are distinct under the action of $\mathrm{SL}_2(\mathbb{Z})$ (each point in the fundamental region F is $\mathrm{SL}_2(\mathbb{Z})$-distinct from every other point in F). Also, by Lemma 2.4.3, $j(\tau)$ is holomorphic on $\mathbb{H}$. Hence, by the open mapping theorem, the image of $j(\tau)$ must be an open set in $\mathbb{C}$. Since the only set that is both open and closed in $\mathbb{C}$ is itself, it is sufficient to prove that $j(\mathbb{H})$ is closed.

Let $j(\tau_k)$ be a sequence in $j(\mathbb{H})$ converging to some $w \in \mathbb{C}$ (where $\tau_k \in \mathbb{H}$). Since $j(\tau)$ is invariant under $\mathrm{SL}_2(\mathbb{Z})$, then by only considering τ in our fundamental domain F, we may assume that each τ_k is such that

$$|\mathrm{Re}(\tau_k)| \leq \frac{1}{2} \ \text{ and } \ |\mathrm{Im}(\tau_k)| \geq \frac{\sqrt{3}}{2}.$$

Suppose the imaginary parts of the τ_k's are unbounded. But then, by Lemma 3.1.3, $j(\tau_k)$ contains a subsequence converging to ∞. Since $j(\tau_k)$ converges to w, this cannot happen. So the imaginary parts of the τ_k's are bounded, say by some $M \in \mathbb{R}$. Hence each τ_k lies in the region

$$R = \left\{ \tau \in \mathbb{H} : |\mathrm{Re}(\tau)| \leq \frac{1}{2}, \frac{\sqrt{3}}{2} \leq |\mathrm{Im}(\tau)| \leq \mathrm{M} \right\},$$

a compact subspace of $\mathbb{H}$. But this implies that τ_k has a subsequence converging to some $\tau_0 \in \mathbb{H}$. Since $j(\tau)$ is continuous and $j(\tau_k)$ converges to w, then $j(\tau_0) = w$, and hence $w \in j(\mathbb{H})$. Thus $j(\mathbb{H})$ is closed, and so $j(\mathbb{H}) = \mathbb{C}$.

□

Thus, through combining Theorem 3.1.2 and Theorem 3.1.5, we have proven Theorem 1.2.4, that $j(\tau)$ is a bijection between $\mathrm{SL}_2(\mathbb{Z})\backslash\mathbb{H}$ and $\mathbb{C}$.

3.2 The Function $j(\tau)$ as a "Modular Function Generator"

Now we turn our sights to Theorem 1.2.5, namely showing that $j(\tau)$ generates all modular functions on $\mathrm{SL}_2(\mathbb{Z})$. Before the big results, we prove a quick lemma:

Lemma 3.2.1. *A modular function f which is holomorphic at ∞ (i.e., its q-expansion has no negative powers of q) is constant.*

Proof. It suffices to show that $f(\mathbb{H} \cup \{\infty\})$ is compact in $\mathbb{C}$; the maximum modulus principle of complex analysis then tells us that f must be constant. We do so by showing that $f(\mathbb{H} \cup \{\infty\})$ is sequentially compact, i.e., every sequence has a subsequence that converges to a point in $f(\mathbb{H} \cup \{\infty\})$. Since $\mathbb{C}$ is a metric space, compactness is equivalent to sequential compactness.

Let $\{f(\tau_k)\}$ be a sequence in $f(\mathbb{H} \cup \{\infty\})$. Since f is modular and thus $\mathrm{SL}_2(\mathbb{Z})$-invariant, we can assume that each τ_k lies in our fundamental region F. If the imaginary parts of the τ_k's are unbounded, then there is a subsequence of $\{\tau_k\}$ converging to $i\infty$. But then there is a subsequence of $\{f(\tau_k)\}$ which converges to $f(\infty)$, which is a finite complex number since f is holomorphic at ∞.

If the imaginary parts of the τ_k's are bounded, say $\mathrm{Im}(\tau_k) \leq M$ for some $M \in \mathbb{R}$, then each τ_k lies in the region $R := \{z \in \mathbb{C} : |z| \geq 1, -1/2 \leq \mathrm{Re}(z) \leq 1/2, \mathrm{Im}(z) \leq M\}$, which is closed and bounded and hence compact. Thus a subsequence of $\{\tau_k\}$ can be found which converges to an element τ_0 of R, and hence $f(\tau_k)$ converges to $f(\tau_0)$, since f is continuous. Hence, $f(\mathbb{H} \cup \{\infty\})$ is compact and thus f must be constant. □

Lemma 3.2.2. *Every holomorphic modular function for $SL_2(\mathbb{Z})$ is a polynomial in $j(\tau)$.*

Proof. Suppose $f(\tau)$ is a holomorphic modular function for $\mathrm{SL}_2(\mathbb{Z})$. Since f is modular and thus meromorphic at the cusp $i\infty$, its q-expansion looks like

$$f(\tau) = \sum_{n=-m}^{\infty} a_n q^n,$$

where m is some positive integer. But the only negative q-power term in $j(\tau)$'s q-expansion is simply q^{-1}. Hence, we can define a polynomial $A(x)$ such that $f(\tau) - A(j(\tau))$ has no terms with negative q powers. So then $f(\tau) - A(j(\tau))$ is holomorphic at ∞ and hence must be constant by Lemma 3.2.1. Thus,

$$f(\tau) = k + A(j(\tau))$$

for some $k \in \mathbb{C}$ and hence $f(\tau)$ is a polynomial in $j(\tau)$. □

And now our goal for this section:

Theorem 3.2.3. *Every modular function for $SL_2(\mathbb{Z})$ is a rational function in $j(\tau)$.*

Proof. Suppose $f(\tau)$ is a modular function for $\mathrm{SL}_2(\mathbb{Z})$. Our goal is to find some polynomial $B(x)$ such that $B(j(\tau))f(\tau)$ is holomorphic. Then applying Lemma 3.2.2, we obtain the desired conclusion.

Because f is modular, it only has a finite number of poles in our fundamental domain F. The idea is to find a polynomial of $j(\tau)$ for each pole that kills each pole of $f(\tau)$, making the resulting function holomorphic at that point.

Let τ_0 be a pole of f of order m. Suppose $j'(\tau_0) \neq 0$. Then consider

$$(j(\tau) - j(\tau_0))^m f(\tau).$$

If we write $j(\tau)$ and $f(\tau)$ as Laurent series about τ_0, we get

$$j(\tau) = \sum_{n=0}^{\infty} a_n(\tau - \tau_0)^n \text{ and } f(\tau) = \sum_{n=-m}^{\infty} b_n(\tau - \tau_0)^n,$$

for some constants a_n and b_n since, at the point τ_0, we know j is holomorphic and f has a pole of order m. Note that $a_0 = j(\tau_0)$.

Then consider

$$(j(\tau) - j(\tau_0))^m f(\tau) = \left(\left(\sum_{n=0}^{\infty} a_n(\tau - \tau_0)^n \right) - a_0 \right)^m f(\tau)$$

$$= \left(\sum_{n=1}^{\infty} a_n(\tau - \tau_0)^n \right)^m \sum_{n=-m}^{\infty} b_n(\tau - \tau_0)^n.$$

The resulting expansion will have no negative powers of $(\tau - \tau_0)$, and hence

$$(j(\tau) - j(\tau_0))^m f(\tau)$$

is holomorphic at τ_0.

Multiplying all such polynomials $(j(\tau) - j(\tau_k))^{m_k}$ corresponding to each of the k poles of f in F yields the polynomial in $j(\tau)$

$$\prod_k (j(\tau) - j(\tau_k))^{m_k}$$

which, when multiplied by f, gives a function that is holomorphic at each pole τ_k.

The only case we have omitted is if we have a pole τ_0 such that $j'(\tau_0) = 0$. It turns out that this only happens at i and $e^{2\pi i/3}$, and similar polynomials in $j(\tau)$ are easily obtained at each point so that their product with $f(\tau)$ gives a suitably holomorphic function. [Cox89]

Thus, multiplying all of our collected polynomials together to get some $B(j(\tau))$, we have that $B(j(\tau))f(\tau)$ is holomorphic, and hence by our previous theorem,

$$f(\tau) = \frac{A(j(\tau))}{B(j(\tau))}$$

for some polynomial $A(x)$.

□

Hence, in proving Theorem 1.2.5, we have shown that $j(\tau)$ can be thought of as the generator of all meromorphic modular functions. Such a function in general is called a **hauptmodul**, a term that will crop up in the statement of monstrous moonshine.

3.3 Denominator Formula

The connection between the j-function and the Monster that we alluded to in the Introduction is actually a specific case of the monstrous moonshine theorem. In fact, Borcherds uses yet another property of $j(\tau)$ to complete a portion of his argument in the proof of moonshine. This property is related to something called the denominator formula [Bor92], and takes the following form:

Theorem 3.3.1. *[Bor92] For $p = e^{2\pi i z}$ and $q = e^{2\pi i \tau}$ with $z, \tau \in \mathbb{H}$, we have that*

$$p^{-1} \prod_{m>0, n\in\mathbb{Z}} (1 - p^m q^n)^{c(mn)} = j(p) - j(q) \tag{3.3}$$

where $j(q) - 744 = \sum_{n=-1}^{\infty} c(n)q^n = q^{-1} + 196884q + \cdots$, and $j(p) := j(z)$ and $j(q) := j(\tau)$.

Proof. We begin by multiplying the left-hand side of equation (3.3) by p and then taking the natural logarithm. So we have

$$\ln\left(\prod_{m>0, n\in\mathbb{Z}} (1 - p^m q^n)^{c(mn)}\right) = \sum_{m>0}\sum_{n\in\mathbb{Z}} \ln(1 - p^m q^n)^{c(mn)} = \sum_{m>0}\sum_{n\in\mathbb{Z}} c(mn)\ln(1 - p^m q^n)$$

by basic logarithm rules. Since $p^m q^n = e^{2\pi i(mz+n\tau)}$ and $c(mn) = 0$ for $n < -1$, then we have that

$$0 < |p^m q^n| < 1.$$

Hence we can use the Laurent expansion for the logarithm in our expression above, and we get

$$\sum_{m>0} \sum_{n\in\mathbb{Z}} \sum_{k>0} -c(mn)\frac{(p^m q^n)^k}{k} = -\sum_{m>0} \sum_{n\in\mathbb{Z}} \sum_{k>0} c(mn)\frac{p^{mk} q^{nk}}{k}.$$

Set $m_0 = mk$, and $n_0 = nk$. Then we have

$$-\sum_{m>0} \sum_{n\in\mathbb{Z}} \sum_{k>0} c(mn)\frac{p^{m_0} q^{n_0}}{k}.$$

By reindexing, and considering the sum over particular m_0's and n_0's instead of k's, we get

$$-\sum_{m>0} \sum_{n\in\mathbb{Z}} \sum_{0<k|(m,n)} \frac{1}{k} c\left(\frac{mn}{k^2}\right) p^m q^n. \tag{3.4}$$

But, by Lemma 2.3.3, we know that, for fixed $m > 0$,

$$\sum_{0<k|(m,n)} \sum_{n\in\mathbb{Z}} \frac{1}{k} c\left(\frac{mn}{k^2}\right) p^m q^n = T_m\left(\sum_{n\in\mathbb{Z}} c(n)q^n\right) p^m,$$

where T_m is the m-th Hecke operator. Hence, expression (3.4) now becomes

$$-\sum_{m>0} T_m\left(\sum_{n\in\mathbb{Z}} c(n)q^n\right) p^m = -\sum_{m>0} T_m(j(q) - 744)p^m.$$

As each T_m is a linear operator on the space of holomorphic modular functions, then this expression can be written

$$\sum_{m>0} f_m(q)p^m,$$

where each f_m is a holomorphic modular function. Now recall that we began by multiplying the left hand side of equation 3.3 by p and taking the logarithm. Hence we have shown that

$$\ln\left(\prod_{m>0, n\in\mathbb{Z}} (1 - p^m q^n)^{c(mn)}\right) = \sum_{m>0} f_m(q)p^m.$$

If we exponentiate our expression and multiply by p^{-1}, then, we get that

$$p^{-1} \prod_{m>0, n\in\mathbb{Z}} (1 - p^m q^n)^{c(mn)} = p^{-1} e^{\sum_{m>0} f_m(q)p^m}.$$

Since e^z is an analytic function with a nice Fourier expansion with respect to p, then this expression becomes

$$p^{-1} \sum_{m\geq 0} h_m(q)p^m,$$

where each h_m is some holomorphic modular function. By Lemma 3.2.2, each $h_m(q)$ can be written as a polynomial in $j(q)$. Thus we get that the left hand side of equation (3.3) is equal to

$$\sum_{m\geq -1} g_m(j(q))p^m,$$

where each g_m is a polynomial. Now we compare this sum with the right hand side of (3.3),

$$j(p) - j(q) = \frac{1}{p} + 744 + \sum_{m\geq 1} c(m)p^m - j(q),$$

clearly a polynomial in $j(q)$. Hence, we have shown that each side of (3.3) can be written as a polynomial of $j(q)$. But, as Borcherds notes in [Bor92], if we know the coefficients of q_n for $n \leq 0$ in a polynomial of $j(q)$, we can determine the polynomial entirely. So it will suffice to show that, in the left hand expansion of (3.3) the coefficient on $\frac{1}{q}$ is -1, the constant term is $j(p) - 744$, and the coefficients for q^n, $n < -1$ are all 0.

First, note that $c(mn)$ is zero whenever $n \leq 0$ and $m > 1$. Hence, the left hand side of (3.3) becomes

$$p^{-1}(1 - p^1q^{-1})^1 \prod_{m>0,n>0} (1 - p^m q^n)^{c(mn)} = (p^{-1} - q^{-1}) \prod_{m>0,n>0} (1 - p^m q^n)^{c(mn)}$$

$$= p^{-1} \prod_{m>0,n>0} (1 - p^m q^n)^{c(mn)} - q^{-1} \prod_{m>0,n>0} (1 - p^m q^n)^{c(mn)}. \tag{3.5}$$

Since $n \geq 1$ in the product, the only $\frac{1}{q}$ term will come from the right-hand product in expression (3.5), multiplying the only constant term in the product, 1. Hence, the coefficient on $\frac{1}{q}$ is, indeed, -1.

As for terms which are constant in q, in the left-hand product in expression (3.5) we just have p^{-1}. In the right-hand product, the constant terms arise when $n = 1$, since then the q^{-1} distributes through and cancels out the q term. So we wish to find the coefficients on the q terms in the product

$$\prod_{m>0} (1 - p^m q)^{c(m)}. \tag{3.6}$$

By the binomial theorem, $(1 - p^m q)^{c(m)} = 1 - c(m)p^m q + \cdots$ for each $m > 1$. So then expression (3.6) looks like

$$\prod_{m>0} (1 - c(m)p^m q + \cdots),$$

so the only q term in our product occurs when that second term multiplies with all the 1's in the other product terms. Thus if we collect all our q terms together, we get

$$q \sum_{m>0} c(m)p^m = q\left(j(p) - \frac{1}{p} - 744\right).$$

But then the q^{-1} knocks out the q, and the only q-constant term we get from our left hand product in (3.5) is $\frac{1}{p}$, so the constant term in the left-hand side of (3.3) is $j(p) - 744$, the same as the q-constant term in the right-hand side.

Thus, the left and right hand sides of (3.3) are equal as polynomials in $j(q)$ and are hence equal.

$\square$

Chapter 4

Monstrous Moonshine

We at last return to the conjecture that connects this wondrous function j to the wondrous group $\mathbb{M}$. As you might imagine, the result is quite wondrous. First, though, we need just one more object before we can actually state the theorem which Borcherds proved.

4.1 The Moonshine Module $V_\natural$

Now that we've introduced the Monster and Representation Theory, we can briefly introduce the Moonshine Module $V_\natural$. In 1988, Igor Frenkel, James Lepowsky, and Arne Meurman constructed the $\mathbb{M}$-module $V_\natural$ (that is, the monster group $\mathbb{M}$ has a group action on $V_\natural$) [FLM88]. The pivotal property of $V_\natural$ is the fact that it can be considered an infinite-dimensional, graded representation of $\mathbb{M}$. This is not a representation in the strict sense (it is infinite dimensional!); rather, $V_\natural$ can be expressed as a direct sum of representations of the Monster, like so:

$$V_\natural = \bigoplus_{n=-1}^{\infty} V_n,$$

where each V_n is a finite representation of the Monster. The construction of $V_\natural$ takes up much of a mathematical tome of 508 pages [FLM88], and will not explicitly be covered here. Suffice to say, the authors constructed $V_\natural$ such that the respective dimensions of each V_n correspond with the coefficients of the j-function's q-expansion. So this representation helps to shed light on the observation noted in the Introduction. Hence $V_\natural$ was named the Moonshine Module, after Conway and Norton's famous conjecture that this representation helped to prove.

4.2 Once Conjecture, Now Theorem

The monstrous moonshine conjecture of Conway and Norton coalesced over the years since they first posed it, reflecting the new discoveries of various algebraic structures. Eventually the conjecture was transformed into something general enough and clear enough to prove. Here is the actual statement of the theorem which Borcherds proved in [Bor92]:

Theorem 4.2.1. *[Bor92] Let* $V = V_\natural = \bigoplus_{n\in\mathbb{Z}}^{\infty} V_n$ *be the Moonshine Module constructed by Frenkel, Lepowsky, and Meurman. Then, for any* $g \in \mathbb{M}$*, the McKay-Thompson series*

$$T_g(q) = \sum_{n=-1}^{\infty} tr(g|V_n)q^n$$

is a hauptmodul for a genus 0 *subgroup of* $\mathrm{SL}_2(\mathbb{R})$*.*

As mentioned in Chapter 3, a Hauptmodul is, in essence, an analogue to the j-function in that a Hauptmodul generates all modular functions for a particular modular subgroup G of $SL_2(\mathbb{R})$. "Genus 0" describes the topological genus of the resulting surface when we take $\mathbb{H}$ and mod out by the action of our group G, then compactify. For example, with $\Gamma = \mathrm{SL}_2(\mathbb{Z})$, then $\Gamma\backslash\mathbb{H}$ can be viewed as the Riemann sphere missing the point at infinity. For a visualization, look at the fundamental region F. The left-hand side is identified with the right-hand side, so "roll up" one side to the other, then tape the bottom edges together. This gives us the Riemann sphere missing infinity. So if we just add in the point at infinity, we get the Riemann sphere, which is a genus 0 topological space.

How does this theorem tie into the j-function, you ask? Well, if we let $g = 1$, the identity element of the Monster, then because each representation V_n has dimension corresponding to the coefficients of the Fourier expansion of $j(\tau)$, we have that

$$T_1(q) = \frac{1}{q} + 196884q + 2149360q^2 + \cdots = j(\tau) - 744.$$

Of course, we can construct a Thompson series for every element $g \in \mathbb{M}$. Since $\mathbb{M}$ has 194 conjugacy classes, then Theorem 2.1.6 tells us that we can expect at most 194 Thompson-Mckay series T_g. In fact, there are only 171 distinct series [Gan04], and, by the moonshine theorem, every one is a Hauptmodul for some genus 0 subgroup of $\mathrm{SL}_2(\mathbb{R})$.

4.3 The Future

The discovery of this fascinating connection between $\mathbb{M}$ and modular functions has led to a wide range of related research. For instance, the question has been asked, "Are there any similar connections between other groups and modular functions?" In 1987, even before monstrous moonshine was actually proved, Conway and Norton synthesized a generalized moonshine conjecture which essentially explores similar connections while generalizing the characters with respect to V_n (see [Car08]). As it is, this conjecture is still unproven, but many other relevant results have been proved along the way.

The exploration of moonshine has led to the creation and examination of various algebraic objects, including vector operator algebras, Kac-Moody algebras, genus 0 functions, and $V_\natural$ itself. Monstrous moonshine has even found purchase in the realm of physics, where it is used to explore something called conformal field theory, a particular quantum field theory on 2-dimensional space-time (see [Gan04] for a brief overview).

Though moonshine now delves ever deeper into strange, new algebraic objects, none of it would be possible without Jay and his monstrous friend.

Abstract

We point out that the elliptic genus of the K3 surface has a natural decomposition in terms of dimensions of irreducible representations of the largest Mathieu group M_{24}. The reason is yet a mystery.

Elliptic genus of a complex D-dimensional hyperKähler manifold M is defined as

$$Z_{ell}(\tau;z)=\mathrm{Tr}_{\mathcal{R}\times\mathcal{R}}(-1)^{F_L+F_R}q^{L_0}\bar{q}^{\bar{L}_0}e^{4\pi izJ^3_{0,L}} \tag{1.1}$$

in terms of the two-dimensional supersymmetric sigma model whose target space is M [1]. As M is assumed to be hyperKähler, the two-dimensional theory has $\mathcal{N}=4$ superconformal algebra as its symmetry. Then L_0 and $\bar{L}_0$ are zero modes of the left- and right-moving Virasoro operators; J^3_0 is the zero mode of the 3rd component of the affine $SU(2)$ algebra; F_L and F_R are the left- and right-moving fermion numbers. Trace is taken over the Ramond sector of the theory. This elliptic genus is a Jacobi form of weight=0 and index $\frac{D}{2}$.

Elliptic genus for K3 surface was explicitly calculated in [2] and is given by

$$Z_{ell}(K3)(\tau;z)=8\left[\left(\frac{\theta_2(\tau;z)}{\theta_2(\tau;0)}\right)^2+\left(\frac{\theta_3(\tau;z)}{\theta_3(\tau;0)}\right)^2+\left(\frac{\theta_4(\tau;z)}{\theta_4(\tau;0)}\right)^2\right]. \tag{1.2}$$

Here $\theta_i(\tau;z)\,(i=2,3,4)$ are Jacobi theta functions. Actually the space of Jacobi forms of weight=0 and index=1 is known to be one-dimensional and thus the above result could have been guessed without explicit computation. We find that $Z_{ell}(K3)(\tau;z=0)=24$ and $Z_{ell}(K3)(\tau;z=1/2)=16+\mathcal{O}(q)$ and thus (1.2) reproduces the Euler number and signature of K3.

In Ref. [2] and more recently in [3] the expansion of the K3 elliptic genus in terms of irreducible representations of $\mathcal{N}=4$ superconformal algebra has been discussed in detail. We first provide the data of representation theory [4, 5]. For a rigorous mathematical exposition, see e.g. [6, 7].

Let us introduce the character formula of the BPS (short) representation of spin $\ell=0$ in Ramond sector with $(-1)^F$ insertion

$$\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z)=\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}\mu(\tau;z), \tag{1.3}$$

$$\mu(\tau;z)=\frac{-ie^{\pi iz}}{\theta_1(\tau;z)}\sum_{n=-\infty}^{\infty}(-1)^n\frac{q^{\frac{1}{2}n(n+1)}e^{2\pi inz}}{1-q^ne^{2\pi iz}}. \tag{1.4}$$

The BPS representation has a non-vanishing index

$$\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z=0)=1. \tag{1.5}$$

We also introduce the character of a non-BPS (long) representation with conformal dimension h

$$q^{h-\frac{3}{8}}\,\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}. \tag{1.6}$$

Then the elliptic genus is expanded as

$$Z_{ell}(K3)(\tau;z)=24\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z)+\Sigma(\tau)\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3} \tag{1.7}$$

where the expansion function $\Sigma(\tau)$ is given by

$$\begin{aligned}\Sigma(\tau) &= -8\left[\mu(\tau;z=\frac{1}{2})+\mu(\tau;z=\frac{1+\tau}{2})+\mu(\tau;z=\frac{\tau}{2})\right] && (1.8)\\ &= -2\,q^{-1/8}\,(1-\sum_{n=1}^{\infty}A_nq^n) && (1.9)\end{aligned}$$

If one uses the relation that the non-BPS representation splits into a sum of BPS representations at the unitarity bound $h=1/4$,

$$q^{-\frac{1}{8}}\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}=2\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z)+\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=\frac{1}{2}}(\tau;z), \tag{1.10}$$

the polar term in Σ may be eliminated and the above decomposition (1.7) can also be written as

$$\begin{aligned}Z_{ell}(K3)(\tau;z) &= 20\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z)-2\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=\frac{1}{2}}(\tau;z)\\ &\quad +2\sum_{n=1}^{\infty}A_nq^{n-\frac{1}{8}}\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}. \qquad (1.11)\end{aligned}$$

The coefficients A_n have been computed explicitly for lower orders by expanding the series (1.8),

n	1	2	3	4	5	6	7	8	9	$\cdots$
A_n	45	231	770	2277	5796	13915	30843	65550	132825	$\cdots$

(1.12)

and it was conjectured that they are all positive integers [8].

On the other hand the asymptotic behavior of A_n at large n has recently been derived using the analogue of the Rademacher expansion of modular forms [3]

$$A_n\approx\frac{2}{\sqrt{8n-1}}e^{2\pi\sqrt{\frac{1}{2}(n-\frac{1}{8})}}. \tag{1.13}$$

It turns out that the above formula (1.13) gives a good estimate of A_n even at smaller values of n and this confirms the positivity of the coefficients A_n. Note that the series $\mu(\tau; z)$ (1.4) has the form of a Lerch sum (or mock theta function) and thus has a complex modular transformation law which involves Mordell's integral. In such a situation we can use the method recently developed by mathematicians [9, 10, 11] and construct the Poincaré-Maas series to derive the above asymptotic formula.

The above table contains a surprise: the first 5 coefficients, $A_1, ..., A_5$, are equal to dimensions of *irreducible* representations of M_{24}, the largest Mathieu group, see Appendix A. The coefficients A_6 and A_7 can also be nicely decomposed as

$$A_6 = 3520 + 10395, \tag{1.14}$$

$$A_7 = 10395 + 5796 + 5544 + 5313 + 2024 + 1771 \tag{1.15}$$

into the sum of dimensions[1]. For $n \geq 8$, it is still possible to decompose A_n into a sum of dimensions of irreducible representations of M_{24}, but decompositions are not as unique.[2]

This observation can be compared to the famous observation of McKay and Thompson[14]: there, the first few terms of the expansion coefficients of $J(q)$,

$$J(q) = \frac{1}{q} + 196884 + 21493760q^2 + \ldots \tag{1.16}$$

could be naturally decomposed into the sum of the dimension of the irreducible representation of the monster simple group. Conway and Norton [15] formulated it in terms of an infinite dimensional graded representation of the monster group $\bigoplus_i V_i$ such that $\dim V_i$ is the coefficient of q^i of $J(q)$, and called this observation the monstrous moonshine. Frenkel, Leopwski and Meurman then found [16] that this representation is naturally assocaited to the two-dimensional string propagating on $\mathbb{R}^{26}/\Lambda/\mathbb{Z}_2$ where Λ is the Leech lattice. See e.g. [17] for a recent review.

---

[1] The tentative decomposition of A_7 shown in the previous of this paper was not correct in view of the later study of twisted elliptic genus in [12, 13]. Here it is corrected according to their papers.

[2] It may also be interesting to point out that $2, 3, 5, 7, 11,$ and 23 appear in prime factorization of A_n more frequently than any other prime numbers and with certain periodicities in n. These are also prime factors of the order of M_{24}.

In our case the existence of a natural vector space whose graded dimension gives $\Sigma(q)$ is guaranteed by construction: it is the Hilbert space of the two-dimensional supersymmetric conformal field theory whose target space is $K3$. The problem is to identify the action of M_{24} on it.[3]

The non-Abelian symplectic symmetry of K3 was studied mathematically by [19, 20]. Mukai enumerated eleven K3 surfaces which possess finite non-Abelian automorphism groups. It turns out that all these groups are various subgroups of the Mathieu group M_{24}, see Appendix B for more details. Is it possible that these automorphism groups at isolated points in the moduli space of K3 surface are enhanced to M_{24} over the whole of moduli space when we consider the elliptic genus? This question is currently under study using Gepner models and matrix factorization.

As discussed in [21], expansion coefficients of elliptic genera of hyperKähler manifolds in general have an exponential growth and are closely related to the black hole entropy. In particular in the case of k-th symmetric product of K3 surfaces we obtain the leading behavior

$$A_n \approx e^{2\pi\sqrt{\frac{k^2}{k+1}n-\left(\frac{k}{2(k+1)}\right)^2}} \tag{1.17}$$

which gives the entropy of the standard D1-D5 black hole $S \approx 2\pi\sqrt{kn}$ at large k ($k = Q_1Q_5$ where Q_1 and Q_5 are the numbers of D1 and D5 branes). Thus the elliptic genus of K3 surface may be considered as describing the multiplicity of microstates of a small black hole with $Q_1 = Q_5 = 1$.

Here the situation is somewhat similar to a model of black hole described by Witten in [22], where microstates of a small black hole span the representation space of the monster group. Although the partition function of the theory is discussed, the relevant CFT is modular invariant separately in left and right sectors and the discussion is effectively the same as considering the elliptic genus.

It will be extremely interesting to see if the Mathieu group M_{24} in fact acts on the elliptic genus of K3.

---

[3] Dong and Mason pursued the analogue of the monstrous moonshine in the case of M_{24}, see e.g. [18] and references therein. So far there is no direct connection of their work and the geometry of K3.

A Data of M_{24}

The largest of the Mathieu group, M_{24}, has

$$2^{10} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 23 = 244823040 \tag{A.1}$$

elements. There are 26 conjugacy classes and 26 irreducible representations. The character table is given in Table 1, whose data is taken from [23, 24]. The conjugacy class is labeled according to the convention of [24]. In the character table, $e_p^\pm$ stands for

$$e_p^\pm = (\pm\sqrt{-p} - 1)/2. \tag{A.2}$$

The dimensions of the irreducible representations are, in the increasing order,

$$\begin{aligned}&1, 23, 45, 45, 231, 231, 252, 253, 483, 770, 770,\\ &990, 990, 1035, 1035, 1035, 1265, 1771, 2024,\\ &2277, 3312, 3520, 5313, 5796, 5544, 10395.\end{aligned} \tag{A.3}$$

Here the irreducible representations of dimensions

$$45, 231, 770, 990, 1035 \tag{A.4}$$

come in complex conjugate pairs. There is in addition an extra real 1035-dimensional irreducible representation.

Table 1: Character table of M_{24}.

B M_{24} and the classical geometry of K3

Here we briefly summarize the relation between the classical geometry of the K3 surface and M_{24}, first found in [19] and elaborated in [20].

Before proceeding, we need to recall the definition of M_{24}. Of many equivalent ways to define it, one that is most understandable to string theorists is to use an even self-dual lattice of dimension 24. Consider the root lattice of A_1 whose generator has squared length 2. Let us denote its weight lattice by A_1^* whose generator has squared length 1/2. Take the 24-dimensional lattice ${A_1}^{24}$. This is even but not self-dual, because the dual lattice is A_1^{*24}. An even self-dual lattice N containing ${A_1}^{24}$ will have the structure

$$ {A_1}^{24} \subset N \subset A_1^{*24}. \tag{B.1} $$

Let $\mathcal{G} = N/{A_1}^{24}$, which is a vector subspace of $A_1^{*24}/{A_1}^{24} \simeq {\mathbb{Z}_2}^{24}$. Let us represent an element of $\mathcal{G}$ by a sequence of twenty-four 0 and 1, and define the weight of a vector to be the number of 1's in it.

The self-duality of N translates to the fact $\mathcal{G}$ is 12-dimensional. The evenness translates to the fact that the weight of every element of $\mathcal{G}$ is a multiple of 4. Let us further demand the vectors of N whose length squared are two are the roots of ${A_1}^{24}$ and not more. Then $\mathcal{G}$ does not have an element with weight 4.

These conditions fix the form of $\mathcal{G}$ uniquely, and $\mathcal{G}$ is known as the extended binary Golay code. M_{24} is defined as the subgroup of the permutation S_{24} of the coordinates of ${\mathbb{Z}_2}^{24}$ which preserves $\mathcal{G}$.

The lattice N thus constructed defines a chiral CFT with $c = 24$ whose current algebra is ${A_1}^{24}$. Therefore M_{24} is the discrete symmetry of this chiral CFT.

Now let us recall that the cohomology lattice of K3,

$$ \Lambda = H^*(K3, \mathbb{Z}) \tag{B.2} $$

is also an even self-dual lattice of dimension 24, but with signature $(4, 20)$. The close connection between M_{24} and the geometry of the K3 surface stems from this fact.

Take a K3 surface S, and let G its symmetry preserving the holomorphic 2-form. Let Λ^G the part of Λ preserved by G, and Λ_G its orthogonal complement. Λ_G is inside the primitive part of $H^{1,1}$, thus it is negative definite. Using Nikulin's result, it can be shown that Λ_G is a sublattice of N. Therefore G is a subgroup of M_{24}.

G cannot be M_{24} itself, however. The action of G on S preserves at least H^0, H^4, $H^{2,0}$, $H^{0,2}$ and the Kähler form. Hence Λ^G is at least five-dimensional, and Λ_G is at most 19-dimensional. This implies that the action of G on N as real linear maps should at least have five-dimensional fixed subspace. This translates to the fact that the action of G on 24 points as a subgroup of M_{24} splits them into at least five orbits.

Similarly, starting from a subgroup G of M_{24} which acts on 24 points with at least five orbits, one can construct the action of G on $H^{1,1}$. Using the global Torelli theorem, this translates to the existence of a K3 surface S whose symmetry is G.

One example is the Fermat quartic, $X^4+Y^4+Z^4+W^4=0$ in $\mathbb{CP}^3$. The symmetry is $(\mathbb{Z}_4)^2 \rtimes S_4$, with 384 elements. This is indeed a subgroup of M_{24} which decomposes 24 points into five orbits, of length 1, 1, 2, 4 and 16.

More examples and details of the analysis can be found in [19] and in [20].

We point out that the elliptic genus of the K3 surface has a natural decomposition in terms of dimensions of irreducible representations of the largest Mathieu group M_{24}. The reason remains a mystery.

1. INTRODUCTION AND CONCLUSIONS

The elliptic genus of a complex D-dimensional hyper-Kähler manifold M is defined as

$$Z_{\text{ell}}(\tau; z) = \text{Tr}_{\mathcal{R}\times\mathcal{R}}(-1)^{F_L+F_R}\, q^{L_0}\, \bar{q}^{\bar{L}_0}\, e^{4\pi i z J^3_{0,L}}$$

in terms of the two-dimensional supersymmetric sigma model whose target space is M [Witten 87]. Since M is assumed to be hyper-Kähler, the two-dimensional theory has $\mathcal{N} = 4$ superconformal algebra as its symmetry. Then L_0 and $\bar{L}_0$ are zero modes of the left- and right-moving Virasoro operators; J^3_0 is the zero mode of the third component of the affine SU(2) algebra; F_L and F_R are the left- and right-moving fermion numbers. The trace is taken over the Ramond sector of the theory. This elliptic genus is a Jacobi form of weight zero and index $D/2$.

The elliptic genus for the K3 surface was explicitly calculated in [Eguchi et al. 89] and is given by

$$Z_{\text{ell}}(K3)(\tau; z) = 8\left[\left(\frac{\theta_2(\tau;z)}{\theta_2(\tau;0)}\right)^2 + \left(\frac{\theta_3(\tau;z)}{\theta_3(\tau;0)}\right)^2 + \left(\frac{\theta_4(\tau;z)}{\theta_4(\tau;0)}\right)^2\right]. \tag{1–1}$$

Here $\theta_i(\tau; z)\,(i = 2, 3, 4)$ are Jacobi theta functions. Actually, the space of Jacobi forms of weight zero and index one is known to be one-dimensional, and thus the above result could have been guessed without explicit computation. We find that $Z_{\text{ell}}(K3)(\tau; z = 0) = 24$ and $Z_{\text{ell}}(K3)(\tau; z = 1/2) = 16 + \mathcal{O}(q)$, and thus (1–1) reproduces the Euler number and signature of K3.

In [Eguchi et al. 89] and more recently in [Eguchi and Hikami 09], the expansion of the K3 elliptic genus in terms of the irreducible representations of the

2000 AMS Subject Classification: 20D08, 14J28, 58J26
Keywords: K3 surface, elliptic genus, Mathieu groups

$\mathcal{N}=4$ superconformal algebra has been discussed in detail. We first provide the data of representation theory [Eguchi and Taormina 87, Eguchi and Taormina 88]. For a rigorous mathematical exposition, see, for example, [Kac 98, Kac and Wakimoto 04].

Let us introduce the character formula of the BPS (short) representation of spin $\ell = 0$ in the Ramond sector with $(-1)^F$ insertion

$$\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z) = \frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}\,\mu(\tau;z), \tag{1–2}$$

$$\mu(\tau;z) = \frac{-ie^{\pi i z}}{\theta_1(\tau;z)} \sum_{n=-\infty}^{\infty} (-1)^n \frac{q^{\frac{1}{2}n(n+1)}\, e^{2\pi i n z}}{1-q^n e^{2\pi i z}}.$$

The BPS representation has nonvanishing index

$$\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau; z=0) = 1.$$

We also introduce the character of a non-BPS (long) representation with conformal dimension h:

$$q^{h-\frac{3}{8}}\,\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}.$$

Then the elliptic genus is expanded as

$$Z_{\mathrm{ell}}(K3)(\tau;z) = 24\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z) + \Sigma(\tau)\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}, \tag{1–3}$$

where the expansion function $\Sigma(\tau)$ is given by

$$\begin{aligned}\Sigma(\tau) &= -8\left[\mu\left(\tau; z=\frac{1}{2}\right) + \mu\left(\tau; z=\frac{1+\tau}{2}\right)\right. \\ &\qquad \left. + \,\mu\left(\tau; z=\frac{\tau}{2}\right)\right] \\ &= -2\,q^{-1/8}\left(1-\sum_{n=1}^{\infty} A_n q^n\right).\end{aligned} \tag{1–4}$$

If one uses the relation that the non-BPS representation splits into a sum of BPS representations at the unitarity bound $h = 1/4$, then

$$q^{-\frac{1}{8}}\,\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3} = 2\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z) + \mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=\frac{1}{2}}(\tau;z),$$

the polar term in Σ may be eliminated, and the decomposition (1–3) can also be written as

$$\begin{aligned}Z_{\mathrm{ell}}(K3)(\tau;z) &= 20\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=0}(\tau;z) - 2\,\mathrm{ch}^{\hat{R}}_{h=\frac{1}{4},\ell=\frac{1}{2}}(\tau;z) \\ &\quad + 2\sum_{n=1}^{\infty} A_n\, q^{n-\frac{1}{8}}\,\frac{\theta_1(\tau;z)^2}{\eta(\tau)^3}.\end{aligned}$$

The coefficients A_n have been computed explicitly for lower orders by expanding the series (1–4) (see Table 1), and it has been conjectured that they are all positive integers [Ooguri 89, Taormina and Wendlend 89, private communication].

n	1	2	3	4	5	6	7	8	$9\cdots$
A_n	45	231	770	2277	5796	13915	30843	65550	$132825\cdots$

TABLE 1. The initial coefficients A_n of the series (1–4)

On the other hand, the asymptotic behavior of A_n at large n has recently been derived using an analogue of the Rademacher expansion of modular forms [Eguchi and Hikami 09]:

$$A_n \approx \frac{2}{\sqrt{8n-1}}\, e^{2\pi\sqrt{\frac{1}{2}\left(n-\frac{1}{8}\right)}}. \tag{1–5}$$

It turns out that (1–5) gives a good estimate of A_n even at smaller values of n, and this confirms the positivity of the coefficients A_n. Note that the series $\mu(\tau;z)$ (1–2) has the form of a Lerch sum (or mock theta function) and thus has a complex modular transformation law that involves Mordell's integral. In such a situation we can use the method recently developed in [Zwegers 02, Bringmann and Ono 06, Bringmann and Ono 08, Zagier 07] and construct the Poincaré–Maass series to derive the above asymptotic formula.

Table 1 contains a surprise: the first five coefficients, $A_1, \ldots, A_5$, are equal to the dimensions of the *irreducible* representations of M_{24}, the largest Mathieu group; see Section 2. The coefficients A_6 and A_7 can also be nicely decomposed as sums of dimensions:[1]

$$\begin{aligned}A_6 &= 3520 + 10395, \\ A_7 &= 10395 + 5796 + 5544 + 5313 + 2024 + 1771.\end{aligned}$$

For $n \geq 8$, it is still possible to decompose A_n into a sum of dimensions of irreducible representations of M_{24}, but the decompositions are not as unique.[2]

This observation can be compared to the famous observation in [Thompson 79], where the first few terms of the expansion coefficients of $J(q)$,

$$J(q) = \frac{1}{q} + 196884 + 21493760q^2 + \cdots, \tag{1–6}$$

could be naturally decomposed into the sum of the dimension of the irreducible representation of the monster simple group. In [Conway and Norton 79] it is formulated in terms of an infinite-dimensional graded representation of the monster group $\bigoplus_i V_i$ such that $\dim V_i$ is the coefficient of q^i of $J(q)$, and Conway and Norton called this observation monstrous moonshine.

---

[1] The tentative decomposition of A_7 shown in a previous version of this paper was incorrect in view of a later study of twisted elliptic genus in [Cheng 10, Gaberdiel et al. 10]. Here it is corrected according to those papers.

[2] It may also be interesting to point out that $2, 3, 5, 7, 11, 23$ appear in the prime factorization of A_n more frequently than any other prime numbers and with certain periodicities in n. These are also prime factors of the order of M_{24}.

It was then found [Frenkel et al. 88] that this representation is naturally associated with the two-dimensional string propagating on $\mathbb{R}^{26}/\Lambda/\mathbb{Z}_2$, where Λ is the Leech lattice. See, for example, [Gannon 04] for a recent review.

In our case, the existence of a natural vector space whose graded dimension gives $\Sigma(q)$ is guaranteed by the construction: it is the Hilbert space of the two-dimensional supersymmetric conformal field theory whose target space is K3. The problem is to identify the action of M_{24} on it.[3]

The nonabelian symplectic symmetry of K3 was studied mathematically in [Mukai 88, Kondo 98]. Mukai enumerated eleven K3 surfaces that possess finite nonabelian automorphism groups. It turns out that all these groups are various subgroups of the Mathieu group M_{24}; see Section 3 for more details. Is it possible that these automorphism groups at isolated points in the moduli space of the K3 surface are enhanced to M_{24} over the whole moduli space when we consider the elliptic genus? This question is currently under study using Gepner models and matrix factorization.

As discussed in [Eguchi and Hikami 10], expansion coefficients of elliptic genera of hyper-Kähler manifolds in general have an exponential growth and are closely related to the black hole entropy. In particular, in the case of the kth symmetric product of the K3 surfaces we obtain the leading behavior

$$A_n \approx e^{2\pi\sqrt{\frac{k^2}{k+1}n-\left(\frac{k}{2(k+1)}\right)^2}},$$

which gives the entropy of the standard D1-D5 black hole $S \approx 2\pi\sqrt{kn}$ at large k ($k = Q_1Q_5$, where Q_1 and Q_5 are the numbers of D1 and D5 branes). Thus the elliptic genus of the K3 surface may be considered as describing the multiplicity of microstates of a small black hole with $Q_1 = Q_5 = 1$.

Here the situation is somewhat similar to a model of black hole described in [Witten 07], where microstates of a small black hole span the representation space of the monster group. Although the partition function of the theory is discussed, the relevant CFT is modular invariant separately in left and right sectors, and the discussion is effectively the same as considering the elliptic genus.

It will be extremely interesting to see whether the Mathieu group M_{24} in fact acts on the elliptic genus of K3.

2. APPENDIX: DATA ON M_{24}

The largest Mathieu group, M_{24}, has

$$2^{10} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 23 = 244823040$$

elements. There are 26 conjugacy classes and 26 irreducible representations. The character table is given in Table 2, whose data are taken from [Math. Soc. Japan 07, Conway et al. 85]. The conjugacy class is labeled according to the convention of [Conway et al. 85]. In the character table, $e_p^\pm$ stands for

$$e_p^\pm = (\pm\sqrt{-p} - 1)/2.$$

The dimensions of the irreducible representations are, in increasing order,

1, 23, 45, 45, 231, 231, 252, 253, 483, 770, 770, 990, 990, 1035, 1035, 1035, 1265, 1771, 2024, 2277, 3312, 3520, 5313, 5796, 5544, 10395.

Here the irreducible representations of dimensions

$$45,\ 231,\ 770,\ 990,\ 1035$$

come in complex conjugate pairs. There is in addition an extra real 1035-dimensional irreducible representation.

3. APPENDIX: M_{24} AND THE CLASSICAL GEOMETRY OF K3

Here we briefly summarize the relation between the classical geometry of the K3 surface and M_{24}, first found in [Mukai 88] and elaborated in [Kondo 98].

Before proceeding, we need to recall the definition of M_{24}. Of many equivalent ways to define it, one that is most understandable to string theorists is to use an even self-dual lattice of dimension 24. Consider the root lattice of A_1 whose generator has squared length 2. Let us denote its weight lattice by A_1^*, whose generator has squared length 1/2. Take the 24-dimensional lattice ${A_1}^{24}$. This is even but not self-dual, because the dual lattice is A_1^{*24}. An even self-dual lattice N containing ${A_1}^{24}$ will have the structure

$${A_1}^{24} \subset N \subset A_1^{*24}.$$

Let $\mathcal{G} = N/{A_1}^{24}$, which is a vector subspace of $A_1^{*24}/{A_1}^{24} \simeq {\mathbb{Z}_2}^{24}$. Let us represent an element of $\mathcal{G}$ by a

---

[3] Dong and Mason pursued the analogue of monstrous moonshine in the case of M_{24}; see, for example, [Dong and Mason 94] and references therein. So far, there is no direct connection between their work and the geometry of K3.

TABLE 2. Character table of M_{24}.

sequence of 24 zeros and ones, and define the weight of a vector to be the number of ones in it.

The self-duality of N translates to the fact that $\mathcal{G}$ is 12-dimensional. The evenness translates to the fact that only the weight of every element of $\mathcal{G}$ is a multiple of 4. Let us further demand that only the vectors of N whose length squared is two be the roots of ${A_1}^{24}$ and not more. Then $\mathcal{G}$ does not have an element with weight 4.

These conditions fix the form of $\mathcal{G}$ uniquely, and $\mathcal{G}$ is known as the extended binary Golay code. The group M_{24} is defined as the subgroup of the permutation group S_{24} of the coordinates of ${\mathbb{Z}_2}^{24}$ that preserves $\mathcal{G}$.

The lattice N thus constructed defines a chiral CFT with $c = 24$ whose current algebra is ${A_1}^{24}$. Therefore M_{24} is the discrete symmetry of this chiral CFT.

Now let us recall that the cohomology lattice of K3,

$$\Lambda = H^*(K3, \mathbb{Z}),$$

is also an even self-dual lattice of dimension 24, but with signature $(4, 20)$. The close connection between M_{24} and the geometry of the K3 surface stems from this fact.

Take a K3 surface S, and let G be its symmetry preserving the holomorphic 2-form. Let Λ^G be the part of Λ preserved by G, and Λ_G its orthogonal complement. Then Λ_G is inside the primitive part of $H^{1,1}$, and thus it is negative definite. Using Nikulin's result, it can be shown that Λ_G is a sublattice of N. Therefore G is a subgroup of M_{24}.

The subgroup G cannot be M_{24} itself, however. The action of G on S preserves at least H^0, H^4, $H^{2,0}$,

$H^{0,2}$, and the Kähler form. Hence Λ^G is at least five-dimensional, and Λ_G is at most 19-dimensional. This implies that the action of G on N as real linear maps should at least have a five-dimensional fixed subspace. This translates to the fact that the action of G on 24 points as a subgroup of M_{24} splits them into at least five orbits.

Similarly, starting from a subgroup G of M_{24} that acts on 24 points with at least five orbits, one can construct the action of G on $H^{1,1}$. Using the global Torelli theorem, this translates to the existence of a K3 surface S whose symmetry is G.

One example is the Fermat quartic $X^4 + Y^4 + Z^4 + W^4 = 0$ in $\mathbb{CP}^3$. The symmetry is $(\mathbb{Z}_4)^2 \rtimes S_4$, with 384 elements. This is indeed a subgroup of M_{24} that decomposes 24 points into five orbits, of lengths 1, 1, 2, 4, and 16.

More examples and details of the analysis can be found in [Mukai 88, Kondo 98].

Abstract

Recently a conjecture has been proposed which attaches (mock) modular forms to the largest Mathieu group. This may be compared to monstrous moonshine, in which modular functions are attached to elements of the Monster group. One of the most remarkable aspects of monstrous moonshine is the following genus zero property: the modular functions turn out to be the generators for the function fields of their invariance groups. In particular, these invariance groups define genus zero quotients of the upper half plane. It is therefore natural to ask if there is an analogue of this property in the Mathieu case, and at first glance the answer appears to be negative since not all the discrete groups arising there have genus zero. On the other hand, in this article we prove that each (mock) modular form appearing in the Mathieu correspondence coincides with the Rademacher sum constructed from its polar part. This property, inspired by the AdS/CFT correspondence in physics, was shown previously to be equivalent to the genus zero property of monstrous moonshine. Hence we conclude that this "Rademacher summability" property serves as the natural analogue of the genus zero property in the Mathieu case. Our result constitutes further evidence that the Rademacher method provides a powerful framework for understanding the modularity of moonshine, and leads to interesting physical questions regarding the gravitational duals of the relevant conformal field theories.

F Modular Forms and Representations 40

1 Introduction

In 2010, an unexpected relation between the elliptic genus of a $K3$ surface and the sporadic group M_{24} was observed by Eguchi, Ooguri and Tachikawa [1]. Subsequently, the connection between the $K3$ elliptic genus twisted by a group element of M_{24} and the characters of M_{24}-representations was first explored in [2, 3], and further studied in [4, 5]. From the point of view of the $K3$ superconformal sigma model, these twisted (or twining) elliptic genera are believed to specify the way in which the $K3$ elliptic cohomology furnishes an M_{24}-representation of infinite dimension. Notice that such a twisted object depends only on the conjugacy class $[g]$ to which the element g belongs. From the $\mathcal{N} = 4$ superconformal symmetry of the sigma model it follows that they are weak Jacobi forms, and moreover admit natural decompositions leading to a set of (mock) modular forms H_g of weight 1/2. As a result of these studies the existence of a natural relationship between representations of M_{24} and the mock modular forms H_g has been conjectured. While such a relationship is yet to be established, extensive evidence has been gathered in [2, 4, 5]. In this context the H_g are often referred to as the McKay–Thompson series and a key prediction of the conjecture is that they exhibit particular modular behaviour under certain discrete subgroups Γ_g of $\mathrm{SL}_2(\mathbb{R})$.

This may be compared to the moonshine conjecture of Conway and Norton [6], which relates genus zero subgroups of $\mathrm{SL}_2(\mathbb{R})$ to elements of the Monster group. More precisely, to each conjugacy class $[g]$ of the Monster is attached a function T_g (its McKay–Thompson series) whose Fourier coefficients are given by characters of the Monster. The genus zero property of monstrous moonshine then refers to the empirical fact (ultimately proven by Borcherds [7]) that T_g defines a function on the upper half plane that generates the function field of its invariance group Γ_g. In particular, the (compactified) quotient of the upper half plane by Γ_g is a Riemann surface of genus zero. This property is also expected to extend to the so-called generalised moonshine [8] which attaches modular functions to commuting pairs of elements of the Monster. Ogg's observation [9] that the normaliser of $\Gamma_0(p)$ in $\mathrm{SL}_2(\mathbb{R})$ for p a prime is genus zero if and only if p divides the order of the Monster was arguably the first hint of a relation between the Monster and genus zero groups.

Assuming the validity of the M_{24} conjecture, and in particular, the validity of the descriptions of the H_g given in [2, 4, 5], a natural question to ask is whether the groups $\Gamma_g \subset SL_2(\mathbb{R})$ attached to the McKay–Thompson series H_g for M_{24} share this fundamental pattern present in monstrous moonshine: do they have a similar genus zero property? At first glance the answer is negative since not all the groups Γ_g arising from M_{24} define genus zero quotients of the upper half plane. When a pattern breaks, we may seek to replace it with a new pattern which encompasses both the old paradigm and the new "exception". Moreover, we also want to understand why a pattern exists at all in the first place. These are exactly the goals of this paper, and these considerations lead us to recast the question in a new form: a form suggested by earlier work of I. Frenkel which reconsidered the origin, and interpretation, of the genus zero property of monstrous moonshine.

The article [10] makes an important step towards a physical explanation of the genus zero property. There it is shown that a discrete group Γ has genus zero if and only if a certain regularisation procedure, inspired by Rademacher's work on the j-function [11] and summarised here as "Reg", renders the Poincaré-like series

$$T_\Gamma(\tau) = \mathrm{Reg}\Big(\sum_{\gamma \in \Gamma_\infty \backslash \Gamma} q^{-1}\big|_\gamma \Big) \tag{1.1}$$

convergent without spoiling invariance under the group Γ. (We say a group Γ has genus zero if it defines a genus zero quotient of the upper half-plane.) In the above formula Γ_∞ is the subgroup of Γ

fixing the cusp (representative) $i\infty$, the sum is over a set of representatives γ for the cosets of Γ_∞ in Γ, and $q = e^{2\pi i\tau}$. As is turns out, the above expression, which we refer to as a *Rademacher sum*, and which can be used to define a function for any discrete subgroup Γ of $\mathrm{SL}_2(\mathbb{R})$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (for example), is anomaly free—that is, invariant under Γ even after the regularisation—if and only if the group Γ has genus zero. In the case that Γ does have genus zero the Rademacher sum (1.1) defines a generator for the field of Γ-invariant functions, and it defines precisely the generator T_g when $\Gamma = \Gamma_g$ for g in the Monster. So the genus zero property of monstrous moonshine may be reformulated as follows:

> The McKay–Thompson series T_g coincides with the Rademacher sum T_Γ attached to its invariance group $\Gamma = \Gamma_g$.

Significantly, Rademacher sums with a higher order pole q^{-n}, which are relevant for conformal field theories (CFTs) with higher central charges, also define modular functions as long as the group Γ has genus zero.

A compelling physical interpretation of the Rademacher sum is provided by the so-called AdS/CFT correspondence [12] (also referred to as the gauge/gravity duality or the holographic duality in more general contexts), which asserts, among many other things, that the partition function of a given two dimensional CFT "with an AdS dual" equals the partition function of another physical theory in three Euclidean dimensions with gravitational interaction and with asymptotically anti de Sitter (AdS) boundary condition and toroidal conformal boundary. There is not yet a systematic understanding of the conditions a CFT has to satisfy in order for it to have an AdS dual. Nevertheless, the correspondence, when applicable, provides both deep intuitive insights and powerful computational tools for the study of the theory. From the fact that the only smooth three-manifold with asymptotically AdS torus boundary condition is a solid torus, it follows that the saddle points of such a partition function are labeled by the different possible ways to "fill in the torus"; that is, the different choices of primitive cycle on the boundary torus which may become contractible in a solid torus that fills it [13]. These different saddle points are therefore labeled by the coset space $\Gamma_\infty\backslash\Gamma$, where $\Gamma = \mathrm{SL}_2(\mathbb{Z})$ [14]. From a bulk, gravitational point of view, the group $\mathrm{SL}_2(\mathbb{Z})$ has an interpretation as the group of large diffeomorphisms, and Γ_∞ is the subgroup that leaves the contractible cycle invariant and therefore can be described by a mere change of coordinates. Such considerations underlie the previous use of Rademacher sums in the physics literature [14, 15, 16, 17, 18, 19].

Apart from the partition function, which computes the dimension of the Hilbert space graded by the basic quantum numbers (the energy, for instance) of the theory, more interesting information can be gained in the presence of a non-trivial symmetry group acting on the Hilbert space by studying the twisted partition function (a trace over the Hilbert space with a group element inserted) which computes the group characters of the Hilbert space. In the Lagrangian formulation of quantum field theories this twisting corresponds to a modification of the boundary condition. Now, in the study of moonshine the McKay–Thompson series attached to the group element g has a physical interpretation as the twisted partition function of a two dimensional CFT with a boundary condition twisted by g. This twisting procedure has a clear geometrical meaning for a two dimensional CFT with an AdS gravity dual: From the point of view of the gravity theory, the change of boundary condition by insertion of a group element g also changes the set of allowed saddle points, and relatedly, the allowed large diffeomorphisms is now given by a different discrete group $\Gamma_g \subset \mathrm{SL}_2(\mathbb{R})$. From this argument, assuming that the moonshine CFT (or its cousins with higher central charges) have semi-classical-like AdS descriptions in which the path integrals are controlled by their saddle points, the modular objects should admit expressions as Rademacher sums over the coset spaces $\Gamma_\infty\backslash\Gamma_g$. This picture motivates the relevance of the Rademacher summability property:

> We say a function f is *Rademacher summable* if it coincides with the Rademacher sum attached to its polar part.

As we have observed above, Rademacher summability is equivalent to the genus zero property in the monstrous case by the results of [10], where the McKay-Thompson series are modular functions. Moreover, the Rademacher summing procedure applied to Γ produces functions which do not have singularities at cusps of Γ other than the infinite one. This is in accordance with our expectation that our theory of gravity should admit a unique low energy description.

The situation is arguably more subtle and also more interesting for M_{24}. As mentioned earlier, in this case the relevant modular objects are weight 1/2 (mock) modular forms, and one does not expect any clear relation between the genus of Γ_g and the Rademacher summability of H_g—indeed, not all the Γ_g attached to elements of M_{24} have genus zero—while in this work we verify explicitly that the functions H_g are all Rademacher summable:

$$H_g(\tau) = -2\,\mathrm{Reg}\Big(\sum_{\gamma\in\Gamma_\infty\backslash\Gamma_g} q^{-1/8}\big|_\gamma\Big) \tag{1.2}$$

for all $g \in M_{24}$. The precise meaning of the above equation will be elucidated in §4, and is in particular the content of the main theorem (Theorem 4.1) of the present paper. Closely related sums for two of the above (mock) modular forms, corresponding to taking g to be the identity or in a certain class of order 2, have been suggested previously in [20]. The function H_g for g the identity is one of the mock modular forms constructed over a decade ago by Pribitkin in [21].

Note the remarkable similarity between (1.2) and (1.1), and recall that Rademacher summability is equivalent to the genus zero property in the monstrous case. In view of this, the Rademacher summability property clearly serves as a natural analogue of the genus zero property, and as a new paradigm that applies to both the Monster and M_{24}. Moreover, Rademacher sums provide a new angle from which to view the moonshine phenomenon: is it not miraculous that the Rademacher machinery, applied with such simple inputs, uniformly produces infinite q-series that contain so much information about sporadic simple groups?

The rest of the paper is organised as follows. In §2 we review the basic properties of the sporadic group M_{24}, focusing on its 24-dimensional permutation representation. In §3 we review the properties of the (mock) modular forms that have been conjectured to encode an infinite-dimensional, $\mathbb{Z}$-graded M_{24} module. In §4 we explain our construction of the Rademacher sums and state the main theorem (Theorem 4.1) of the present paper. The rest of the paper is devoted to the proof of Theorem 4.1. In §5 we discuss the convergence of the Rademacher sums and establish that these sums are indeed convergent given the convergence of certain Selberg–Kloosterman zeta functions, which will be shown in §9. Having established the convergence of the sums, in §6 we give explicit expressions for the Fourier coefficients of our Rademacher sums, and discuss their asymptotic growth. In §7 we study the transformation properties of the Rademacher sums and establish their (mock) modularity. Given the modularity and information about their behaviour at the cusps, in §8 we finally establish that the Rademacher sums constructed in §4 indeed coincide with the (mock) modular forms which are the proposed McKay–Thompson series for the group M_{24} described in §3.

2 The Largest Mathieu Group

We shall start by recalling some facts about the largest Mathieu group. The group M_{24} may be characterised as the automorphism group of the unique doubly even self-dual binary code of length 24 with no words of weight 4, also known as the *(extended) binary Golay code*. In other words, there is a unique (up to permutation) set, $\mathcal{G}$ say, of length 24 binary codewords (sequences of 0's and 1's) such that any other length 24 codeword has even overlap with all the codewords of $\mathcal{G}$ if and only if this word itself is in $\mathcal{G}$, and the number of 1's in each codeword of $\mathcal{G}$ is divisible by and not equal to 4. The group of permutations of the 24 coordinates that preserves the set $\mathcal{G}$ is the sporadic group M_{24}. See, for instance, [22].

$[g]$	cycle shape	$\eta_g(\tau)$	k_g	n_g	N_g	h_g
$1A$	1^{24}	$\eta^{24}(\tau)$	12	1	1	1
$2A$	$1^8 2^8$	$\eta^8(\tau)\eta^8(2\tau)$	8	2	2	1
$2B$	2^{12}	$\eta^{12}(2\tau)$	6	2	4	2
$3A$	$1^6 3^6$	$\eta^6(\tau)\eta^6(3\tau)$	6	3	3	1
$3B$	3^8	$\eta^8(3\tau)$	4	3	9	3
$4A$	$2^4 4^4$	$\eta^4(2\tau)\eta^4(4\tau)$	4	4	8	2
$4B$	$1^4 2^4 4^4$	$\eta^4(\tau)\eta^2(2\tau)\eta^4(4\tau)$	5	4	4	1
$4C$	4^6	$\eta^6(4\tau)$	3	4	16	4
$5A$	$1^4 5^4$	$\eta^4(\tau)\eta^4(5\tau)$	4	5	5	1
$6A$	$1^2 2^2 3^2 6^2$	$\eta^2(\tau)\eta^2(2\tau)\eta^2(3\tau)\eta^2(6\tau)$	4	6	6	1
$6B$	6^4	$\eta^4(6\tau)$	2	6	36	6
$7AB$	$1^3 7^3$	$\eta^3(\tau)\eta^3(7\tau)$	3	7	7	1
$8A$	$1^2 2^1 4^1 8^2$	$\eta^2(\tau)\eta(2\tau)\eta(4\tau)\eta^2(8\tau)$	3	8	8	1
$10A$	$2^2 10^2$	$\eta^2(2\tau)\eta^2(10\tau)$	2	10	20	2
$11A$	$1^2 11^2$	$\eta^2(\tau)\eta^2(11\tau)$	2	11	11	1
$12A$	$2^1 4^1 6^1 12^1$	$\eta(2\tau)\eta(4\tau)\eta(6\tau)\eta(12\tau)$	2	12	24	2
$12B$	12^2	$\eta^2(12\tau)$	1	12	144	12
$14AB$	$1^1 2^1 7^1 14^1$	$\eta(\tau)\eta(2\tau)\eta(7\tau)\eta(14\tau)$	2	14	14	1
$15AB$	$1^1 3^1 5^1 15^1$	$\eta(\tau)\eta(3\tau)\eta(5\tau)\eta(15\tau)$	2	15	15	1
$21AB$	$3^1 21^1$	$\eta(3\tau)\eta(21\tau)$	1	21	63	3
$23AB$	$1^1 23^1$	$\eta(\tau)\eta(23\tau)$	1	23	23	1

Table 1: The cycle shapes, weights (k_g), levels (N_g) and orders (n_g) of the 26 conjugacy classes of the sporadic group M_{24}. The length of the shortest cycle is $h_g = N_g/n_g$. The naming of the conjugacy classes follows the ATLAS convention (cf. [23]). We write $7AB$, for example, to indicate that the entries of the incident row are valid for both the conjugacy classes $7A$ and $7B$.

As such, M_{24} naturally admits a permutation representation of degree 24, and this allows us to assign a *cycle shape* to each of its elements. For example, to the identity element we associate the cycle shape 1^{24}; to an element of M_{24} that is a product of 12 mutually commuting transpositions we associate the cycle shape 2^{12}, and so on. More generally, any cycle shape arising from an element of M_{24} (or S_{24}, for that matter) is of the form

$$i_1{}^{\ell_1} i_2{}^{\ell_2} \cdots i_r{}^{\ell_r}, \quad \sum_{s=1}^{r} \ell_s \, i_s = 24 \, ,$$

for some $\ell_s \in \mathbb{Z}^+$ and $1 \leq i_1 < \cdots < i_r \leq 23$ with $r \geq 1$. Clearly, the cycle shape of an element of M_{24} depends only on its conjugacy class, denoted by $[g]$, although different conjugacy classes can share the same cycle shape. For future reference we denote the character underlying this defining 24-dimensional representation of M_{24} by χ. The value of the character $\chi(g)$ equals the number of fixed points of g in the action on the set of 24 points. In particular, note that $\chi(g) = \ell_1$ in case $i_1 = 1$ and $\chi(g) = 0$ otherwise.

It turns out that the cycle shapes of M_{24} have many special properties that will be important for the understanding of the modular properties of the associated McKay–Thompson series which we will discuss shortly. First, the M_{24} cycle shapes are privileged in that they are all of the so-called *balanced type* (cf. [6]), meaning that for each $g \in M_{24}$ there exists a positive integer N_g such that if $\prod i_s^{\ell_s}$ is the cycle shape associated to g then

$$\prod_s i_s^{\ell_s} = \prod_s \left(\frac{N_g}{i_s}\right)^{\ell_s} .$$

We will refer to the number N_g as the *level* of the g.

If g has cycle shape $i_1^{\ell_1} \cdots i_r^{\ell_r}$ then the order of g is the least common multiple of the i_s's. A second special property of $[g] \subset M_{24}$ is that the order of g coincides with the length i_r of the longest cycle in the cycle shape. Henceforth we will denote $n_g = i_r$.

Finally, observe that for all $g \in M_{24}$ the level N_g defined above equals the product of the shortest and the longest cycle. Hence we have $h_g n_g = N_g$ where h_g denotes the length of the shortest cycle in the cycle shape. Moreover, we also have the property $h_g | n_g$ and $h_g | 12$. This is very reminiscent of the monstrous moonshine [6]. We also set $k_g = \sum_{s=1}^{r} \ell_s / 2$ to be half of the total number of cycles and call it the *weight* of g. Of course, N_g, n_g, h_g and k_g depend only on the conjugacy class $[g]$ containing g and can be found in Table 1.

To each element $g \in M_{24}$ we can attach an *eta-product*, to be denoted η_g, which is the function on the upper half-plane given by

$$\eta_g(\tau) = \prod_s \eta(i_s \tau)^{\ell_s} \tag{2.1}$$

where $\prod_s i_s^{\ell_s}$ is the cycle shape attached to g, and $\eta(\tau)$ is the Dedekind eta function satisfying $\eta(\tau) = q^{1/24} \prod_{n \in \mathbb{Z}^+} (1 - q^n)$ for $q = e(\tau)$, where for later convenience, here and everywhere else in this paper we will use the shorthand notation

$$e(x) = e^{2\pi i x} .$$

As was observed in [24, 25], the eta-product η_g associated to an element $g \in M_{24}$ (or rather, to its conjugacy class $[g]$) is a cusp form of weight k_g for the group $\Gamma_0(N_g)$, with a *Dirichlet character* ς_g that is trivial if the weight k_g is even and is otherwise defined, in terms of the Jacobi symbol $(\frac{n}{m})$, by

$$\varsigma_g(\gamma) = \begin{cases} \left(\frac{N_g}{d}\right)(-1)^{\frac{d-1}{2}}, & d \text{ odd,} \\ \left(\frac{N_g}{d}\right), & d \text{ even,} \end{cases}$$

in case d is the lower right entry of $\gamma \in \Gamma_0(N_g)$. Let's recall that

$$\Gamma_0(N) = \left\{ \gamma \middle| \ \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \,, \ c = 0 \mod N \right\} .$$

The eta-product η_g also defines a cusp form of weight k_g on the larger (or equal) group $\Gamma_0(n_g) \supseteq \Gamma_0(N_g)$ if we allow for a slightly more sophisticated multiplier system. We remark here that, according to our conventions, a function $\xi : \Gamma \to \mathbb{C}^*$ is called a *multiplier system for* Γ *of weight* w in case the identity

$$\xi(\gamma\sigma)\,\mathrm{jac}(\gamma\sigma,\tau)^{w/2} = \xi(\gamma)\xi(\sigma)\,\mathrm{jac}(\gamma,\sigma\tau)^{w/2}\,\mathrm{jac}(\sigma,\tau)^{w/2} \tag{2.2}$$

holds for all $\gamma,\sigma \in \Gamma$ and $\tau \in \mathbb{H}$. Writing $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, we have in the above formula $\gamma\tau = \frac{a\tau+b}{c\tau+d}$, and the Jacobian

$$\mathrm{jac}(\gamma,\tau) = (c\tau+d)^{-2}\ .$$

In detail, for $\gamma \in \Gamma$, we define the *slash operator* $|_{\xi,w}$ *of weight* w *associated with multiplier* ξ as

$$(f|_{\xi,w}\gamma)(\tau) = \xi(\gamma)f(\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{w/2}\ , \tag{2.3}$$

and in particular a holomorphic function $f : \mathbb{H} \to \mathbb{C}$ is a modular form of weight w and multiplier ξ on Γ if and only if $(f|_{\xi,w}\gamma)(\tau) = f(\tau)$ for all $\gamma \in \Gamma$. In the present case we have

$$\Big(\frac{1}{\eta_g}\Big|_{\xi_g,k_g}\gamma\Big)(\tau) = \frac{1}{\eta_g(\tau)} \quad , \quad \text{for all} \quad \gamma \in \Gamma_0(n_g)\ , \tag{2.4}$$

where $\xi_g(\gamma) = \rho_{n_g|h_g}(\gamma)\varsigma_g(\gamma)$ with

$$\rho_{n|h}(\gamma) = \mathrm{e}(-\tfrac{1}{(\gamma\infty-\gamma 0)nh}) = \mathrm{e}(-cd/nh)\ . \tag{2.5}$$

Note that $\rho_{n_g|h_g}$ is actually a character on $\Gamma_0(n_g)$ since we have that $xy \equiv 1 \pmod{h_g}$ implies $x \equiv y \pmod{h_g}$ by virtue of the fact that $h_g = N_g/n_g$ is a divisor of 24 for every $g \in M_{24}$ (cf. [6, §3]). Evidently the kernel of $\rho_{n|h}$ is $\Gamma_0(nh)$, and in particular, $\rho_{n|h}$ is trivial on Γ_∞.

These (meromorphic) modular forms $1/\eta_g(\tau)$ have also the interpretation as the partition function of a the conformal field theory of 24 free chiral bosons, twisted by $g \in M_{24}$ which acts on the 24 bosons as an element of S_{24}. As such, they are also McKay–Thompson series whose Fourier coefficients are positive-integral linear combinations of M_{24} characters. See Table 4 for the first ten M_{24}-representations appearing in $1/\eta_g(\tau)$. Following an earlier observation in [26], it was shown in [2] that they are connected to the elliptic genera of $K3$ surfaces and the moonshine for M_{24} which will be discussed in the next section, via a lifting to Siegel modular forms and generalised Kac-Moody superalgebras. More details will be given in [27].

Observe that the behaviour of the multipliers naturally divides the conjugacy classes of M_{24} into two types: those for which the phase is trivial on $\Gamma_0(n_g)$ and those for which it is not. The former occurs just when $h_g = 1$, and the elements of $g \in M_{24}$ with $h_g > 1$ are exactly the classes which act fixed-point-freely in the defining permutation representation on 24 points. The elements with $h_g = 1$ have at least one fixed point and thus can be located in a (maximal) subgroup of M_{24} isomorphic to the second largest Mathieu group, M_{23}.

3 Mock Modular Forms

In the recent article [1] a remarkable observation relating M_{24} and the unique (up to scale) weak Jacobi form of weight zero and index one, here denoted $Z(\tau, z)$, was made via a decomposition of the latter object into a combination of mock theta series and mock modular forms. As is shown in [28, 29, 20], the function $Z(\tau,z)=8\sum_{i=2,3,4}(\frac{\theta_i(\tau,z)}{\theta_i(\tau,0)})^2$ admits an expression

$$Z(\tau,z)=\frac{\theta_1(\tau,z)^2}{\eta(\tau)^3}\left(a\,\mu(\tau,z)+q^{-1/8}\big(b+\sum_{k=1}^{\infty}t_k\,q^k\big)\right) \tag{3.1}$$

with $a,b,t_k\in\mathbb{Z}$ for all $k\in\mathbb{Z}^+$ where $\mu(\tau,z)$ denotes the *Appell-Lerch sum*, satisfying

$$\mu(\tau,z)=\frac{-iy^{1/2}}{\theta_1(\tau,z)}\sum_{\ell=-\infty}^{\infty}\frac{(-1)^\ell y^n q^{\ell(\ell+1)/2}}{1-yq^\ell}$$

for $q=e(\tau)$ and $y=e(z)$. The Jacobi theta functions are given by

$$\begin{aligned}\theta_1(\tau,z)&=-iq^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^{n-1})\\ \theta_2(\tau,z)&=q^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1-q^n)(1+yq^n)(1+y^{-1}q^{n-1})\\ \theta_3(\tau,z)&=\prod_{n=1}^{\infty}(1-q^n)(1+y\,q^{n-1/2})(1+y^{-1}q^{n-1/2})\\ \theta_4(\tau,z)&=\prod_{n=1}^{\infty}(1-q^n)(1-y\,q^{n-1/2})(1-y^{-1}q^{n-1/2})\ .\end{aligned} \tag{3.2}$$

By inspection, $a=24=\chi(1A)$, $b=-2$ and the first few t_k are

$$2\times 45,\ 2\times 231,\ 2\times 770,\ 2\times 2277,\ 2\times 5796\cdots$$

These positive integers t_k have the interpretation of enumerating the k-th massive representations of the $\mathcal{N}=4$ superconformal algebra in the elliptic genus of a $K3$ surface.

The surprising connection to M_{24}, beyond the fact that $a=24$ is the dimension of the defining permutation representation of M_{24}, is the following: the integers 45, 231, 770, 2277 and 5796, which are the $t_k/2$ for $k=1,2,3,4,5$, are the dimensions of irreducible representations of M_{24}. It was conjectured that the entire set of values t_k for $k\in\mathbb{Z}^+$ encode the graded dimension of a naturally defined graded M_{24} module $K=\bigoplus_k K_k$ with $\dim K_k=t_k$. If the conjecture holds then we can obtain new functions by replacing t_k with $\mathrm{tr}_{K_k}g$ for $g\in M_{24}$. This idea was first investigated in [2], and independently in [3]; see also [4] and [5]. It is an idea that we pursue further in this article.

Define $H(\tau)$ so that $Z(\tau,z)\eta(\tau)^3=\theta_1(\tau,z)^2(a\mu(\tau,z)+H(\tau))$. Then

$$H(\tau)=q^{-\frac{1}{8}}\left(-2+\sum_{k=1}^{\infty}t_kq^k\right) \tag{3.3}$$

so that $H(\tau)$ is (essentially) a power series incorporating the t_k, and hence the graded dimension of the conjectural M_{24} module K. This function $H(\tau)$ enjoys a special relationship with the group $\mathrm{SL}_2(\mathbb{Z})$; namely, it is a *weakly holomorphic mock modular form of weight* $1/2$ on $\mathrm{SL}_2(\mathbb{Z})$ with *shadow* $24\,\eta(\tau)^3$ (cf. [30]), which means that $H(\tau)$ is a holomorphic function on the upper half-plane $\mathbb{H}$

with at most exponential growth as $\tau \to \alpha$ for any $\alpha \in \mathbb{Q}$, and if we define the *completion* of $H(\tau)$, to be denoted $\hat{H}(\tau)$, by setting

$$\hat{H}(\tau) = H(\tau) + 24\,(4i)^{-1/2} \int_{-\bar{\tau}}^{\infty} (z+\tau)^{-1/2}\overline{\eta(-\bar{z})^3}\mathrm{d}z,$$

then $\hat{H}(\tau)$ transforms as a modular form of weight $1/2$ on $\mathrm{SL}_2(\mathbb{Z})$ with multiplier system conjugate to that of $\eta(\tau)^3$. In other words, we have

$$\big(\hat{H}(\tau)|_{\epsilon^{-3},1/2}\gamma\big)(\tau) = \epsilon(\gamma)^{-3}\hat{H}(\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{1/4} = \hat{H}(\tau)$$

for $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, where $\epsilon : \mathrm{SL}_2(\mathbb{Z}) \to \mathbb{C}^*$ is the multiplier system for $\eta(\tau)$ satisfying

$$\big(\eta|_{\epsilon,1/2}\gamma\big)(\tau) = \eta(\tau)\ .$$

(See §A for an explicit description of ϵ.)

More generally, a holomorphic function $h(\tau)$ on $\mathbb{H}$ is called a *(weakly holomorphic) mock modular form of weight w* for a discrete group Γ (e.g. a congruence subgroup of $\mathrm{SL}_2(\mathbb{R})$) if it has at most exponential growth as $\tau \to \alpha$ for any $\alpha \in \mathbb{Q}$, and if there exists a holomorphic modular form $g(\tau)$ of weight $2-w$ on Γ such that $\hat{h}(\tau)$, given by

$$\hat{h}(\tau) = h(\tau) + (4i)^{w-1} \int_{-\bar{\tau}}^{\infty} (z+\tau)^{-w}\overline{g(-\bar{z})}\mathrm{d}z, \tag{3.4}$$

is a (non-holomorphic) modular form of weight w for Γ for some multiplier system ψ say. In this case the function g is called the *shadow* of the mock modular form h and we call ψ the multiplier system of h.

If the conjectural M_{24}-module K exists, apart from $H(\tau)$ there must be a family of functions $H_g(\tau)$, for each conjugacy class $[g] \subset M_{24}$, obtainable by replacing each t_k with the trace of g on K_k. These are the McKay–Thompson series given by

$$H_g(\tau) = q^{-\frac{1}{8}}\left(-2 + \sum_{k=1}^{\infty} \mathrm{tr}_{K_k}(g) q^k\right)\ . \tag{3.5}$$

Explicit expressions for these function $H_g(\tau)$ have been proposed in [2, 3], mostly for conjugacy classes with $h_g = 1$, and completed for all $[g] \subset M_{24}$ in [4, 5]. These proposals state that they are given by $H(\tau)$, the character $\chi(g)$ of g in the 24-dimensional representation, and certain weight two modular forms $\tilde{T}_g(\tau)$ for the group $\Gamma_0(N_g)$, by

$$H_g(\tau) = \frac{\chi(g)}{24}H(\tau) - \frac{\tilde{T}_g(\tau)}{\eta(\tau)^3}\ . \tag{3.6}$$

These data are collected in Table 2. The expression (3.6) makes manifest that the q-series $H_g(\tau)$ is a mock modular form with shadow $\chi(g)\eta^3(\tau)$, and is in particular a usual modular form when $h_g > 1$, or equivalently, $\chi(g) = 0$. Moreover, it is easy to check that $H_g(\tau)$ transforms nicely under the group $\Gamma_0(n_g)$, with the multiplier system $\psi(\gamma) = \epsilon(\gamma)^{-3}\rho_{n_g|h_g}(\gamma)$. Notice that the extra multiplier ρ that appears when $h_g \neq 1$ is the same as that of the inverse eta-products $1/\eta_g(\tau)$ which are also related to M_{24}, a fact that is in accordance with the 1/2- and 1/4-BPS spectrum of the

$[g]$	$\chi(g)$	$\tilde{T}_g(\tau)$

Table 2: In this table we collect the data that via equation (3.6) define the weight 1/2 (mock) modular forms $H_g(\tau)$. For $N \in \mathbb{Z}_+$, we denote by Λ_N the weight 2 modular form on $\Gamma_0(N)$ given by $\Lambda_N = Nq\frac{d}{dq}(\log\frac{\eta(N\tau)}{\eta(\tau)})$ (cf. (8.13)). For $N=23$, there are two new forms and we choose the basis $\phi_{23,1}=\eta^2_{23AB}$ and $\phi_{23,2}$ given in (8.14).

$\mathcal{N}=4$, d=4 theory obtained by $K3\times T^2$ compactification of the type II string theory. These mock modular forms $H_g(\tau)$ are the central objects of study in this work.

Although the conjecture (3.5) stating that the Fourier coefficients of $H_g(\tau)$ are all given by characters of M_{24}-module still remains to be proven, it has been checked up to the first 1000 terms. We list the first few in Table 5. Together with other pieces of evidence, this makes it an extremely plausible conjecture. In this paper we will hence assume the validity of this conjecture as a part of our motivation, while our main result (Theorem 4.1) holds independent of it.

4 Rademacher Sums

In this section we will state and explain the main theorem (Theorem 4.1) of the paper, while postponing the proof till the later sections.

Recall that $H(\tau)$ is a mock modular form of weight 1/2 on $\mathrm{SL}_2(\mathbb{Z})$ with a multiplier system given by $\epsilon(\gamma)^{-3}$ and with leading term $-2q^{-1/8}$ in its q-expansion. We may consider the problem of attaching a function with these data via Rademacher sums, and also analogous functions to discrete subgroups of $\mathrm{SL}_2(\mathbb{R})$ other than the modular group[1].

---

[1] For the purpose of establishing relations to M_{24} it suffices to look at subgroups of $\mathrm{SL}_2(\mathbb{Z})$, while it is possible to

Let Γ be a finite index subgroup of $\mathrm{SL}_2(\mathbb{Z})$ containing the group Γ_∞ of upper triangular matrices in $\mathrm{SL}_2(\mathbb{Z})$. In particular, we assume that Γ contains $-\mathrm{Id}$. Define $R_\Gamma(\tau)$ by setting

$$R_\Gamma(\tau) = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \epsilon(\gamma)^{-3}\,\mathrm{e}(-\tfrac{\gamma\tau}{8})\,\mathrm{reg}(\gamma,\tau)\,\mathrm{jac}(\gamma,\tau)^{1/4}\ , \tag{4.1}$$

where $\mathrm{reg}(\gamma,\tau)$ is the *Rademacher regularisation factor (of weight* $1/2$ *and index* $-1/8$*)*, defined by $\mathrm{reg}(\gamma,\tau)=1$ in case γ is upper triangular (i.e. $\gamma\cdot\infty=\infty$) and

$$\mathrm{reg}(\gamma,\tau) = \mathrm{e}(\tfrac{\gamma\tau-\gamma\infty}{8})\ \mathrm{e}(\tfrac{\gamma\infty-\gamma\tau}{8},\tfrac{1}{2}) \tag{4.2}$$

otherwise, where $\mathrm{e}(x,s)$ is the following generalisation of the exponential function:

$$\mathrm{e}(x,s) = \sum_{m\geq 0}\frac{(2\pi i x)^{m+s}}{\Gamma(m+s+1)}\ . \tag{4.3}$$

Note that we recover $\mathrm{e}(x)=e^{2\pi i x}$ by taking $s=0$ in $\mathrm{e}(x,s)$, and for n a positive integer $\mathrm{e}(x,n)$ is the difference between $\mathrm{e}(x)$ and the order $n-1$ Taylor approximation to $\mathrm{e}(x)$. It is also closely related to the incomplete Gamma function $\Gamma(s,x)=\int_x^\infty t^{s-1}e^t\mathrm{d}t$: applying integration by parts repeatedly, we obtain

$$\mathrm{e}(x,s) = \frac{\mathrm{e}(x)}{\Gamma(s)}\int_0^{2\pi i X} t^{s-1}e^t\mathrm{d}t\ . \tag{4.4}$$

Let T be the element of Γ_∞ such that $\mathrm{tr}(T)=2$ and $T\tau=\tau+1$. Note that two elements γ,σ of Γ are in the same right coset of Γ_∞ if and only if there is some $n\in\mathbb{Z}$ such that $\sigma=T^n\gamma$ or $-T^n\gamma$. In particular, they have the same lower rows up to multiplication by $\pm\mathrm{Id}$ and we can therefore use the lower rows to parametrise the cosets. This motivates the sum over the "rectangle" in (4.1): For any given positive K, we consider a sum over a set $\{\gamma\}$ of representatives for the cosets of Γ_∞ in Γ whose elements have lower rows (c,d) satisfying $0\leq c<K$ and $-K^2<d<K^2$. Using a superscript $^\times$ to indicate a sum over coset representatives other than the trivial one, we have

$$(\Gamma_\infty\backslash\Gamma)^\times_{<K} = \left\{\Gamma_\infty\gamma \mid 0<c<K,\ -K^2<d<K^2\right\}\ . \tag{4.5}$$

Here and everywhere else we use (c,d), a shorthand for $(c(\gamma),d(\gamma))$, to denote the lower row entries when writing γ as a 2×2 matrix. Complimented with a term given by the trivial coset (the one with a representative $\gamma=$Id), this is the range of the sum, denoted by $(\Gamma_\infty\backslash\Gamma)_{<K}$, taken in (4.1). With a slight abuse of notation, we use $\gamma\in\Gamma_\infty\backslash\Gamma$ to denote a sum over a representative from each coset.

To ensure that (4.1) is well-defined we require to check that the summands are invariant under the replacement of γ with $\pm T^n\gamma$ for $n\in\mathbb{Z}$. Obviously $\mathrm{reg}(T^n\gamma,\tau)=\mathrm{reg}(\gamma,\tau)$ for any n, and γ and $-\gamma$ act in the same way on $\mathbb{H}$ as well as on the cusp representatives so the Rademacher regularisation factor has the required invariance. Left multiplication by T does not change the lower row of γ so the factor $\mathrm{jac}(\gamma,\tau)^{1/4}$ is invariant under the substitution of $T^n\gamma$ for γ. Using the explicit description (A.6) for ϵ we see that $\epsilon(T^n\gamma)=\mathrm{e}(-\frac{n}{24})\,\epsilon(\gamma)$, so that the product $\epsilon(\gamma)^{-3}\,\mathrm{e}(-\frac{\gamma\tau}{8})$, is also invariant under the substitution of $T^n\gamma$ for γ, and then the identity $\epsilon(-\gamma)^{-3}\,\mathrm{jac}(-\gamma,\tau)^{1/4}=\epsilon(\gamma)^{-3}\,\mathrm{jac}(\gamma,\tau)^{1/4}$ completes the verification that every summand of (4.1) is invariant under the replacement of γ with $\pm T^n\gamma$.

---

generalise the analysis to $\mathrm{SL}_2(\mathbb{R})$ subgroups commensurable to $\mathrm{SL}_2(\mathbb{Z})$

While the regularisation factor might seem ad hoc at the first sight, here we would like to argue that it is in fact strictly necessary and very natural. First, to motivate the appearance of a regularisation note that a series

$$\sum_{\gamma\in\Gamma_\infty\backslash\Gamma} \psi(\gamma)\,\mathrm{e}(\alpha\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{w/2}, \tag{4.6}$$

for α a real constant and ψ a (compatible) multiplier system of weight w on Γ, will generally not converge (absolutely and uniformly on compacta) unless $w>2$. (In case it does converge it defines a modular form of weight w on Γ.) In [11] Rademacher demonstrated a method to regularise this sum for $\psi\equiv 1$, $\alpha=-1$ and $w=0$ in the case that $\Gamma=\mathrm{SL}_2(\mathbb{Z})$. His prescription may be described as follows: multiplying each summand by the regularisation factor $\mathrm{r}^0(-1,\gamma,\tau)$ which is 1 when γ is upper triangular and

$$\mathrm{e}(\gamma\tau-\gamma\infty)\,\mathrm{e}(\gamma\infty-\gamma\tau,1)=\mathrm{e}(\gamma\tau-\gamma\infty)(\mathrm{e}(\gamma\infty-\gamma\tau)-1)$$

otherwise, and replacing the sum over the coset space $\Gamma_\infty\backslash\Gamma$ with a limit of sums over rectangles $(\Gamma_\infty\backslash\Gamma)_{<K}$, we obtain

$$\mathrm{e}(-\tau)+\lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} \mathrm{e}(-\gamma\tau)-\mathrm{e}(-\gamma\infty)\ .$$

He then went on to prove (cf. loc. cit.) that this expression converges and defines an $\mathrm{SL}_2(\mathbb{Z})$ invariant function on the upper half-plane, which is nothing but the familiar j-function (up to an additive constant). More generally, in [10], for example, it is shown that for $\psi\equiv 1$ and $\alpha, w/2\in\mathbb{Z}$, inclusion of the factor

$$\mathrm{r}^{w/2}(\alpha,\gamma,\tau)=\mathrm{e}(\alpha(\gamma\infty-\gamma\tau))\,\mathrm{e}(\alpha(\gamma\tau-\gamma\infty),1-w)$$

for summands corresponding to cosets with upper triangular representatives, together with a limit of sums over rectangles, regularises the sum (4.6) for Γ a subgroup of $\mathrm{SL}_2(\mathbb{R})$ that is commensurable with the modular group. Putting $\alpha=-1/8$ and $w=1/2$, we recover exactly our regularisation factor (4.2). It is rather surprising that this straightforward generalisation of regularisation scheme does its job in regularising the sum in (4.1).

To understand the modular properties of R_Γ, it is useful to consider the companion function S_Γ defined by

$$S_\Gamma(\tau)=\lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \epsilon(\gamma)^3\,\mathrm{e}(\tfrac{\gamma\tau}{8})\,\mathrm{jac}(\gamma,\tau)^{3/4}. \tag{4.7}$$

According to the philosophy of the previous paragraph S_Γ, supposing it converges, should have modular transformations of weight 3/2 for Γ with multiplier system coinciding with that of $\eta(\tau)^3$. Also, we should have that $S_\Gamma=\mathcal{O}(q^{1/8})$ as $\tau\to\infty$. It will develop in §7 that R_Γ is a mock modular form and that S_Γ is its shadow.

Remark. The functions $\hat\Sigma(\tau)$ and $\hat\Sigma^\circ(\tau)$ of [20] are recovered by taking $\Gamma=\mathrm{SL}_2(\mathbb{Z})$ and $\Gamma=\Gamma_0(2)$, respectively, in $\hat R_\Gamma(\tau)$, up to a factor of -2. We will demonstrate presently that $R_\Gamma(\tau)=\Sigma(\tau)/2$ for $\Sigma(\tau)$ is as in loc. cit. when $\Gamma=\Gamma_0(1)$.

Apart from considering the Rademacher with $\psi(\gamma)=\epsilon^{-3}(\gamma)$, to construct the M_{24} McKay–Thompson series we also need to extend the above construction to the cases with a more general multiplier system ψ. In particular, we would sometimes like to consider different Rademacher sums with the same group Γ but different multipliers.

Given a group morphism $\rho : \Gamma \to \mathbb{C}^*$ that is trivial on Γ_∞ we may consider the following twists of R_Γ and S_Γ:

$$\begin{aligned} R_{\Gamma,\rho}(\tau) &= \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \psi(\gamma)\, \mathrm{e}(-\tfrac{\gamma\tau}{8})\, \mathrm{reg}(\gamma,\tau)\, \mathrm{jac}(\gamma,\tau)^{1/4} \\ S_{\Gamma,\rho}(\tau) &= \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \bar{\psi}(\gamma)\, \mathrm{e}(\tfrac{\gamma\tau}{8})\, \mathrm{jac}(\gamma,\tau)^{3/4} \end{aligned} \tag{4.8}$$

where we have $\psi(\gamma) = \rho(\gamma)\epsilon(\gamma)^{-3}$. In this paper we will take $\Gamma = \Gamma_0(n)$ for some $n \in \mathbb{Z}^+$ and $\rho = \rho_{n|h}$ given in (2.5) for h simultaneously dividing n and 24. Not surprisingly, later on we are going to take (n,h) to be the (n_g,h_g) coming from the cycle shapes of M_{24} as given by Table 1.

To ease notation, we write $R_{n|h}$ for $R_{\Gamma,\rho}$ when $\Gamma = \Gamma_0(n)$ and $\rho = \rho_{n|h}$, and we apply the directly analogous interpretation to the $S_{n|h}$. The main result in this article is the following.

Theorem 4.1. *Let $g \in M_{24}$. Then $H_g = -2R_{n|h}$ when $n = n_g$ and $h = h_g$.*

The rest of the paper is devoted to the proof of the above theorem.

5 Convergence

After defining the Rademacher sums formally in the last section, in this section we would like to discuss the convergence of the sums. An integral step towards Theorem 4.1 is to prove its convergence. It is a rather subtle issue and in this section we will establish it conditional upon a hypothesis whose validity will be established in §9. To be more precise, the aim in this section is to demonstrate that if the Selberg–Kloosterman zeta function (5.7) attached to $\psi = \rho\epsilon^{-3}$ and $\Gamma = \Gamma_0(n)$ converges at $s = 3/4$ for some character ρ on Γ then the limits (4.1) and (4.7) defining the Rademacher sums $R_{\Gamma,\rho}$ and $S_{\Gamma,\rho}$, respectively, define holomorphic functions on the upper half-plane.

Our arguments in this section owe a lot to the work of Niebur in [31]. We cannot apply his results verbatim since he worked with (mock) modular forms of negative weight and ours have positive weight, but many of the procedures we employ have a counterpart in loc. cit.

Let $\Gamma = \Gamma_0(n)$ for some positive integer n and $\psi(\gamma) = \rho(\gamma)\epsilon(\gamma)^{-3}$ for some character ρ on Γ satisfying $\rho(\gamma) = \rho(T\gamma) = \rho(\gamma T)$. According to the definitions of $R_{\Gamma,\rho}$ and $S_{\Gamma,\rho}$, we can separate the contribution from the trivial coset and the rest in the following way

$$\begin{aligned} R_{\Gamma,\rho}(\tau) &= q^{-1/8} + \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} R_\gamma(\tau) \\ S_{\Gamma,\rho}(\tau) &= q^{1/8} + \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} S_\gamma(\tau)\ . \end{aligned}$$

Using the expression of the (generalised) exponentials as infinite sums and isolating the first term in the sum, we obtain $R_\gamma(\tau) = R^0_\gamma(\tau) + R^+_\gamma(\tau)$ and $S_\gamma(\tau) = S^0_\gamma(\tau) + S^+_\gamma(\tau)$, where

$$\begin{aligned} R^0_\gamma &= e(\tfrac{1}{8})\, \psi(\gamma)\, \mathrm{e}(-\tfrac{\gamma\infty}{8})\, c^{-3/2}\, (\tau - \gamma^{-1}\infty)^{-1} \\ S^0_\gamma &= \bar{\psi}(\gamma)\, \mathrm{e}(\tfrac{\gamma\infty}{8})\, c^{-3/2}\, (\tau - \gamma^{-1}\infty)^{-3/2} \end{aligned} \tag{5.1}$$

and

$$\begin{aligned} R^+_\gamma &= \psi(\gamma)\,\mathrm{e}(-\tfrac{\gamma\infty}{8})\sum_{m=1}^{\infty}\frac{c^{-2m-3/2}(\tau-\gamma^{-1}\infty)^{-m-1}(2\pi i/8)^{m+1/2}}{\Gamma(m+3/2)} \\ S^+_\gamma &= \bar{\psi}(\gamma)\,\mathrm{e}(\tfrac{\gamma\infty}{8})\sum_{m=1}^{\infty}\frac{c^{-2m-3/2}(\tau-\gamma^{-1}\infty)^{-m-3/2}(-2\pi i/8)^{m}}{m!}\ . \end{aligned} \tag{5.2}$$

We have also applied the identities

$$\mathrm{jac}(\gamma,\tau)=c^{-2}(\tau-\gamma^{-1}\infty)^{-2}\quad,\quad \gamma\infty-\gamma\tau=c^{-2}(\tau-\gamma^{-1}\infty)^{-1}$$

in rewriting the above expressions. With these definitions, we have the following:

Lemma 5.1. *The sums* $\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times}R^+_\gamma(\tau)$ *and* $\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times}S^+_\gamma(\tau)$ *are absolutely convergent, locally uniformly for* $\tau\in\mathbb{H}$.

Proof. We give details for the first sum. A very similar argument takes care of the second one.

By (5.2) we have that $R^+_\gamma(\tau)=\mathcal{O}(c^{-7/2}\,|\tau-\gamma^{-1}\infty|^{-2})$ as $c\to\infty$. For $\Gamma=\Gamma_0(n)$, the representatives of the non-trivial cosets in the coset space $\Gamma_\infty\backslash\Gamma$ are indexed by their lower rows which are tuples of two integers (c,d) with $c>0$ and $n|c$, $\gcd(c,d)=1$. A procedure we will repeatedly use is to split the sum over d into the following double sum

$$\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times}f(c,d)=\sum_{\substack{0<c\\ n|c}}\sum_{\substack{0\le d'<c\\ (c,d')=1}}\sum_{\ell\in\mathbb{Z}}f(c,d'+\ell c) \tag{5.3}$$

for an arbitrary function $f(x,y)$. Notice that the above sum over the tuple (c,d') can be viewed as the sum over a complete and irredundant set of representatives of a double coset in $\Gamma_\infty\backslash\Gamma/\Gamma_\infty$.

Taking $f(x,y)=x^{-7/2}|\tau+y/x|^{-2}$ we find that

$$\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times}|R^+_\gamma(\tau)|\ll\sum_{\substack{0<c\\ n|c}}c^{-7/2}\sum_{\substack{0\le d'<c\\ (c,d')=1}}\sum_{\ell\in\mathbb{Z}}|\tau+d'/c+\ell|^{-2}.$$

Since there are not more than c invertible elements in the ring $\mathbb{Z}/c$, we conclude that the sum $\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times}R^+_\gamma(\tau)$ is absolutely convergent, locally uniformly for $\tau\in\mathbb{H}$, as required. ☐

Hence, in order to show the convergence of the sums defining $R_{\Gamma,\rho}(\tau)$ and $S_{\Gamma,\rho}(\tau)$ it now suffices to establish the convergence of the limits

$$\lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}}R^0_\gamma(\tau),\quad \lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}}S^0_\gamma(\tau), \tag{5.4}$$

and apply Lemma 5.1.

After carefully examining the limit and employing the Lipschitz summation formula in the form of Lemma C.1, the first of the above sums can be rewritten as

$$\lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}}R^0_\gamma(\tau)=2\pi\,\mathrm{e}(-\tfrac18)\sum_{k=1}^{\infty}\mathrm{e}((k-\tfrac18)\tau)\lim_{K\to\infty}\sum_{\substack{0<c<K\\ n|c}}c^{-3/2}S(0,k,c,\psi)\ , \tag{5.5}$$

where we have used the *generalised Kloosterman sum* (cf. [32]) for a given group Γ:

$$S(m,\ell,c,\xi)=\sum_{\substack{\gamma\in\Gamma_\infty\backslash\Gamma/\Gamma_\infty\\ c(\gamma)=c}}\xi(\gamma)\,\mathrm{e}((m-\alpha)\gamma\infty)\,\mathrm{e}(-(\ell-\alpha)\gamma^{-1}\infty) \tag{5.6}$$

for $\ell\in\mathbb{Z}$, where for $m,\ell,c\in\mathbb{Z}$ with $0<c$ and ξ a multiplier system on Γ, the value $0\leq\alpha<1$ is determined by ξ according to the requirement that $\xi(T)=\mathrm{e}(\alpha)$. An important object closely related to the generalised Kloosterman sum is the *Selberg–Kloosterman zeta function* of Γ (cf. loc. cit.), defined as

$$Z_{m,\ell}(s,\psi)=\sum_{c>0}\frac{S(m,\ell,c,\psi)}{c^{2s}}\,. \tag{5.7}$$

The details of the manipulation leading to (5.5) are given in Appendix D.

Hence, as promised, if we assume the convergence of $Z_{0,k}(s,\rho\epsilon^{-3})$ at $s=3/4$ we will have shown the convergence of the first sum in (5.4), and hence $R_{\Gamma,\rho}$ upon using Lemma (5.1). The convergence of the Selberg–Kloosterman zeta function will be demonstrated in §9. Finally, a similar but less subtle argument also establishes the convergence of the second sum in (5.4). In particular, in the case of S^0_γ the application of the Lipschitz summation formula is less delicate: We can apply (C.1) with $s=3/2,\alpha=7/8$ and the error term E_K is absent. Taken together we have the following:

Proposition 5.2. *The expression (4.1) defining $R_{\Gamma,\rho}(\tau)$ converges, locally uniformly for $\tau\in\mathbb{H}$, thus defining a holomorphic function on $\mathbb{H}$. Also, the expression (4.7) defining $S_{\Gamma,\rho}(\tau)$ converges, locally uniformly for $\tau\in\mathbb{H}$, thus defining a holomorphic function on $\mathbb{H}$.*

In practice it is useful to know that there is some flexibility in the sum over “rectangles” in the definition of $R_{\Gamma,\rho}$ and $S_{\Gamma,\rho}$ (cf. (4.1) and (4.7)). For example, given $\sigma\in\Gamma$ we may consider the sums

$$\lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma}R_\gamma(\tau),\qquad \lim_{K\to\infty}\sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma}S_\gamma(\tau), \tag{5.8}$$

where $(\Gamma_\infty\backslash\Gamma)_{<K}\sigma$ denotes the “parallelogram” that is the image of $(\Gamma_\infty\backslash\Gamma)_{<K}$ under right multiplication by σ. The following result can be proved by using the technique employed in Lemma 4.3 of [31] to extend the convergence arguments appearing already in this section. We suppress the details.

Lemma 5.3. *Let $\sigma\in\Gamma$, and let $R_\gamma(\tau)$ and $S_\gamma(\tau)$ be as in (5.1) and (5.2), respectively. Then the expressions in (5.8) converge uniformly for $\tau\in\mathbb{H}$, thus defining holomorphic functions on $\mathbb{H}$. Moreover these functions coincide with $R_{\Gamma,\rho}(\tau)$ and $S_{\Gamma,\rho}(\tau)$ respectively.*

6 Coefficients

A common motivation to study Rademacher sums is to obtain an exact expression for the Fourier coefficients of a given infinite q-series. In this section we will give such expressions for the functions $R_{\Gamma,\rho}$ and $S_{\Gamma,\rho}$. They are useful, for instance, in the physical study of the growth (6.2) of the twisted indices of supersymmetric states—the (twisted) entropy—as the energy of the states gets large.

In the last section we have seen that, by splitting the sum over representatives of cosets $\Gamma_\infty\backslash\Gamma$ into a double sum over those of the double cosets $\Gamma_\infty\backslash\Gamma/\Gamma_\infty$ and over all integers $\ell\in\mathbb{Z}$, and applying the Lipschitz summation formula (C.2), we obtain expressions (5.5) for the objects (5.4) as an infinite q-series. In this section we would like to show that the same can be done for the full $R_{\Gamma,\rho}, S_{\Gamma,\rho}$, and write down explicit expressions for the infinite q-series that the infinite sums (4.8) converge to.

Following similar steps as delineated in the last section, this time with the help of equation (C.1), it is not difficult to prove that the functions $R_{\Gamma,\rho}, S_{\Gamma,\rho}$ can be written as q-series with the following Fourier coefficients

$$\begin{aligned} c_{\Gamma,\rho}(k-\tfrac{1}{8}) &= \frac{2\pi\ \mathrm{e}(-\frac{1}{8})}{(8k-1)^{1/4}} \sum_{\substack{0<c\\ n|c}} \frac{1}{c} I_{1/2}\left(\frac{\pi}{2c}(8k-1)^{1/2}\right) S(0,k,c,\psi) \\ c^{*}_{\Gamma,\rho}(k+\tfrac{1}{8}) &= \mathrm{e}(-\tfrac{3}{8})\, 2\pi (8k+1)^{1/4} \sum_{\substack{0<c\\ n|c}} \frac{1}{c} J_{1/2}\left(\frac{\pi}{2c}(8k+1)^{1/2}\right) S(1,k+1,c,\bar{\psi})\ , \end{aligned} \tag{6.1}$$

where $S(m,\ell,c,\psi)$ again denotes the generalised Kloosterman sum (5.6) and $\psi = \rho\epsilon^{-3}$.

First note that the q-series with the above coefficients indeed define holomorphic functions on $\mathbb{H}$. To start with, again assuming the convergence of the Selberg–Kloosterman zeta function $Z_{0,k}(\frac{3}{4},\psi)$, we will show that the sums (over c) in (6.1) converge: Observe that since $c^{-1}I_{1/2}(\frac{\pi}{2c}\sqrt{8k-1})$ is bounded by a constant times $c^{-3/2}$ for c sufficiently large (cf. (B.5)), the convergence of the right hand side of (6.1) is guaranteed by the convergence of $Z_{0,k}(\frac{3}{4},\psi)$. We establish the convergence of $Z_{0,k}(\frac{3}{4},\psi)$ for $k\in\mathbb{Z}$ in §9 for the case that $\Gamma=\Gamma_0(n)$ and $\rho=\rho_{n|h}$ for some h dividing both n and 24. From the above argument we see that this result implies the convergence of both the $c_{\Gamma,\rho}(k-\frac{1}{8})$ for $k>0$ and the $c^{*}_{\Gamma,\rho}(k+\frac{1}{8})$ for $k\geq 0$.

Once armed with the convergence of the terms $c_{\Gamma,\rho}(k-\frac{1}{8})$ and $c^{*}_{\Gamma,\rho}(k+\frac{1}{8})$ we may consider the following series

$$\sum_{k\geq 1} c_{\Gamma,\rho}(k-\tfrac{1}{8})q^{k-1/8}, \quad \sum_{k\geq 0} c^{*}_{\Gamma,\rho}(k+\tfrac{1}{8})q^{k+1/8}.$$

The Bessel function $I_{1/2}(x)$ is asymptotic to $e^x/\sqrt{2\pi x}$ for large x (cf. §B) so $c_{\Gamma,\rho}(k-\frac{1}{8})$ is dominated by the first term in the summation over c in (6.1) for n sufficiently large, and similarly for $c^{*}_{\Gamma,\rho}(k+\frac{1}{8})$; in the case that $\Gamma=\Gamma_0(n)$ this is the term with $c=n$. We then have

$$c_{\Gamma,\rho}(k-\tfrac{1}{8}) = \mathcal{O}\left(\frac{e^{\pi\sqrt{8k-1}/2n}}{\sqrt{8k-1}}\right) \tag{6.2}$$

as $k\to\infty$ and a similar estimate holds for $c^{*}_{\Gamma,\rho}(k+\frac{1}{8})$. In particular, we may conclude that the series $\Phi_{\Gamma,\rho}$ and $\Phi^{*}_{\Gamma,\rho}$, defined by

$$\Phi_{\Gamma,\rho}(\tau) = q^{-1/8} + \sum_{k\geq 1} c_{\Gamma,\rho}(k-\tfrac{1}{8})q^{k-1/8}, \tag{6.3}$$

$$\Phi^{*}_{\Gamma,\rho}(\tau) = q^{1/8} + \sum_{k\geq 0} c^{*}_{\Gamma,\rho}(k+\tfrac{1}{8})q^{k+1/8}, \tag{6.4}$$

converge absolutely and locally uniformly for $\tau\in\mathbb{H}$ upon identifying $q=\mathrm{e}(\tau)$.

We summarise the discussion of the previous two paragraphs in the following lemma.

Lemma 6.1. *The expressions (6.1) defining* $c_{\Gamma,\rho}(k-\frac{1}{8})$ *and* $c^*_{\Gamma,\rho}(k+\frac{1}{8})$ *converge. Further, the generating series (6.3) and (6.4) for the* $c_{\Gamma,\rho}(k-\frac{1}{8})$ *and* $c^*_{\Gamma,\rho}(k+\frac{1}{8})$ *converge absolutely and locally uniformly for* $\tau \in \mathbb{H}$*, thus defining holomorphic functions* $\Phi_{\Gamma,\rho}(\tau)$ *and* $\Phi^*_{\Gamma,\rho}(\tau)$ *on* $\mathbb{H}$*. These functions coincide with* $R_{\Gamma,\rho}(\tau)$ *and* $S_{\Gamma,\rho}(\tau)$ *respectively.*

7 Variance

After establishing the convergence of the Rademachers sums $R_{\Gamma,\rho}$ and $S_{\Gamma,\rho}$, in this section we wish to determine how they transform under the action of Γ. In particular, we will show that $S_{\Gamma,\rho}$ is a weight 3/2 cusp form and $R_{\Gamma,\rho}$ is a weight 1/2 mock modular form on Γ. Moreover, the shadow of $R_{\Gamma,\rho}$ is given by $S_{\Gamma,\rho}$.

As before, we have $\Gamma = \Gamma_0(n)$ for some positive integer n, and let $\rho = \rho_{n|h}$ (cf. (2.5)) for some h dividing both n and 24 and set $\psi = \rho\epsilon^{-3}$. The variance of the Rademacher sum $S_{\Gamma,\rho}$ can be easily established, and we have

Proposition 7.1. *The function* $S_{\Gamma,\rho}(\tau)$ *is a cusp form of weight* $3/2$ *for* Γ *with multiplier system* $\overline{\psi}$*.*

Proof. Since ϵ^3 is the multiplier of the cusp form $\eta^3(\tau)$ and ρ is a group character satisfying $\rho(\gamma)\rho(\sigma) = \rho(\gamma\sigma)$ for all $\gamma, \sigma \in \Gamma_0(n)$, we see that $\bar{\psi} = \rho^{-1}\epsilon^3$ is a weight 3/2 multiplier system, which leads immediately to

$$S_\gamma|_{\overline{\psi},3/2}\sigma = S_{\gamma\sigma} \tag{7.1}$$

for $\sigma \in \Gamma$, where S_γ is as defined in (5.1)-(5.2). Moreover, when $h = 1$ and hence ρ is trivial, this also holds more generally for $\sigma \in \mathrm{SL}_2(\mathbb{Z})$.

Applying Lemma 5.3 to $S_{\Gamma,\rho} = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} S_\gamma(\tau)$ and using (7.1), we immediately have $S_{\Gamma,\rho}|_{\overline{\psi},3/2}\sigma = S_{\Gamma,\rho}$ for $\sigma \in \Gamma$. This establishes that $S_{\Gamma,\rho}$ is a modular form of weight 3/2 for Γ with multiplier system $\overline{\psi}$. We also need to show that $S_{\Gamma,\rho}$ vanishes at all cusps. For the cusp at ∞, this is clear from Lemma 6.1. We will now show that it is also true for the other cusps of Γ.

An important property of a given cusp is its width. Suppose $\kappa \in \mathbb{Q}$ is a representative of a cusp of $\Gamma \subset \mathrm{SL}_2(\mathbb{Z})$ that is related to the infinite cusp by $\sigma\infty = \kappa$, $\sigma \in \mathrm{SL}_2(\mathbb{Z})$. We define the *width* u of the cusp κ to be the positive integer such that the subgroup of Γ stabilising κ is given by

$$\Big\{\gamma \in \Gamma \Big| \gamma\kappa = \kappa\Big\} = \sigma\langle \pm T^u\rangle\sigma^{-1} = \sigma\Gamma^u_\infty\sigma^{-1}\ . \tag{7.2}$$

Alternatively, we can rephrase the above definition using the concept of a 'scaling element' which will become important later. Consider an element $\tilde{\sigma} \in \mathrm{SL}_2(\mathbb{R})$, to be called a *scaling element* of Γ at cusp κ, such that $\kappa = \tilde{\sigma}\infty$ and the subgroup of Γ stabilising κ is given by $\tilde{\sigma}\Gamma_\infty\tilde{\sigma}^{-1}$ (Cf. [10, §2.6]). Such a scaling element necessarily has the form

$$\tilde{\sigma} = \sigma U T^\beta \quad , \quad \text{with} \quad \sigma \in \mathrm{SL}_2(\mathbb{Z})\ ,\ \beta \in \mathbb{Q}\ , \tag{7.3}$$

where $U = \left(\begin{smallmatrix}\sqrt{u} & 0\\ 0 & 1/\sqrt{u}\end{smallmatrix}\right)$ maps $\tau \to u\tau$ and $T^\beta = \left(\begin{smallmatrix}1 & \beta\\ 0 & 1\end{smallmatrix}\right)$.

Given a cusp representative $\kappa = \sigma\infty$ of width v of $\Gamma_0(n)$, in order to study the behaviour of $S_{n|h}$ at κ, it is convenient to consider the function $S^{(\kappa)}_{n|h}(\tau)$ which we will now define. For a given scaling element $\tilde{\sigma}$, for $h = 1$ we define

$$S^{(\kappa)}_{n|1}(\tau) = S_{n|1}\big|_{\epsilon^3,3/2}\sigma(v(\tau+\beta)) = \epsilon^3(\sigma)\,\mathrm{jac}(\sigma, v(\tau+\beta))^{3/4} S_{n|h}(\tilde{\sigma}\tau)\ .$$

From (7.1) we get

$$S^{(\kappa)}_{n|1}(\tau) = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} S_\gamma(v(\tau+\beta)) \ .$$

Splitting the above sum into a sum over the double coset $(\Gamma_\infty\backslash\Gamma)_{<K}\sigma/\Gamma^v_\infty$ and applying the Lipschitz summation formula as before, we obtain that $S^{(\kappa)}_{n|1}(\tau)$ takes the form of an infinite series $\sum_{k=0}^\infty c^{*(\kappa)}_{\Gamma,\rho}(k+\nu)\,\mathrm{e}((k+\nu)\tau)$ where $0<\nu\le 1$ differs from $\frac{v}{8}$ by an integer. This proves that $S_{n|1}$ vanishes at κ.

More generally, for $h\neq 1$ we again consider

$$\begin{aligned} S_{n|h}\big|_{\epsilon^3,3/2}\sigma(\tau) &= \epsilon^3(\sigma)\,\mathrm{jac}(\sigma,\tau)^{3/4} S_{n|h}(\sigma\tau) \\ &= \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} \rho^{-1}(\gamma\sigma^{-1})\epsilon^3(\gamma)\,\mathrm{jac}(\gamma,\tau)^{3/4}\,\mathrm{e}(\tfrac{\gamma\tau}{8}) \ . \end{aligned} \tag{7.4}$$

If κ has width v in $\Gamma_0(n)$ and has width u in $\Gamma_0(nh)$, we can define for a given scaling element $\tilde\sigma$

$$S^{(\kappa)}_{n|h}(\tau) = S_{n|h}\big|_{\epsilon^3,3/2}\sigma\,(u(\tau+\beta)) \ .$$

To obtain its expression as an infinite series, define $0\le m<h$ such that $\rho(\sigma T^v\sigma^{-1}) = \mathrm{e}(\frac{m}{h})$ and proceed as before, ultimately obtainin the general expression

$$S^{(\kappa)}_{n|h}(\tau) = \sum_{k=0}^\infty c^{*(\kappa)}_{\Gamma,\rho}(k+\nu)\,\mathrm{e}((k+\nu)\tfrac{u}{v}\tau) \quad , \quad 0<\nu\le 1 \ . \tag{7.5}$$

More precisely, $\nu = \{\{\frac{m}{h}+\frac{v}{8}\}\}$ is given by the sawtooth function $\{\{x\}\}$ defined as the difference between a real number and the largest integer that is smaller than it:

$$\{\{x\}\} = \begin{cases} x-\lfloor x\rfloor & x\in\mathbb{R}\backslash\mathbb{Z} \\ 1 & x\in\mathbb{Z} \end{cases}$$

where the floor function $\lfloor x\rfloor$ denotes the largest integer not exceeding x. This shows that $S_{n|h}(\tau)$ vanishes at all cusps of $\Gamma_0(n)$ and thereby finishes the proof. ☐

Our next task is to establish the variance of the Rademacher sum $R_{\Gamma,\rho}$.

Proposition 7.2. *The function $R_{\Gamma,\rho}$ is a mock modular form of weight $1/2$ on Γ with multiplier system ψ and with shadow $S_{\Gamma,\rho}$.*

Proof. First observe that $R_\gamma = \psi(\gamma)\,\mathrm{e}(-\frac{\gamma\tau}{8})\,\mathrm{jac}(\gamma,\tau)^{1/4}\mathrm{reg}(\gamma,\tau)$ would transform nicely if it weren't for the regularisation factor. Therefore, it would be useful to separate from R_γ the "unregularised" part

$$P_\gamma(\tau) = \psi(\gamma)\,\mathrm{e}(-\gamma\tau/8)\,\mathrm{jac}(\gamma,\tau)^{1/4}, \tag{7.6}$$

for $\gamma\in\Gamma$, and consider

$$R_\gamma(\tau) - P_\gamma(\tau) = \psi(\gamma)\,\mathrm{e}(-\tfrac{\gamma\infty}{8})\,\mathrm{jac}(\gamma,\tau)^{1/4}\,(\mathrm{e}(X,1/2)-\mathrm{e}(X))$$

with $X = \frac{\gamma\infty - \gamma\tau}{8}$. Using the definition (4.4), we have

$$\mathrm{e}(X,s) - \mathrm{e}(X) = -\frac{\mathrm{e}(X)}{\Gamma(s)} \int_{2\pi i X}^{\infty} e^{-t} t^{s-1}\, dt \;.$$

Setting $t = \frac{2\pi i}{8}(\gamma z - \gamma\tau)$ in the integral and using the identity

$$\mathrm{jac}(\gamma, z)\,\mathrm{jac}(\gamma,\tau)(z-\tau)^2 = (\gamma z - \gamma\tau)^2 \tag{7.7}$$

we get

$$\mathrm{e}(X,1/2) - \mathrm{e}(X) = \frac{1}{2}\,\mathrm{e}(\tfrac{1}{8})\,\mathrm{e}(\tfrac{\gamma\infty}{8})\,\mathrm{jac}(\gamma,\tau)^{-1/4} \int_{\gamma^{-1}\infty}^{\infty} \mathrm{e}(-\tfrac{\gamma z}{8})\,\mathrm{jac}^{3/4}(\gamma,z)\,(z-\tau)^{-1/2}\, dz \;.$$

It will be convenient to introduce an integral operator J_x for x in the extended upper half-plane $(\mathbb{H} \cup \mathbb{Q} \cup \infty)$ which acts on a holomorphic function g on $\mathbb{H}$ (with sufficiently rapid decay as $\Im(z) \to \infty$) as

$$(J_x g)\,(\tau) = \frac{\mathrm{e}(\frac{1}{8})}{2} \int_{\bar{x}}^{\infty} \bar{g}(z)(z-\tau)^{-1/2} \mathrm{d}z \;. \tag{7.8}$$

From the definition (3.4), we see that we have a weight 1/2 mock modular form with shadow g if $\hat{h} = h + J_\tau g$ transforms as a weight 1/2 modular form.

Comparing with the definition of the integral operator J_x, we have

$$R_\gamma(\tau) - P_\gamma(\tau) = \left(J_{\gamma^{-1}\infty} S_\gamma\right)(\tau) \;.$$

Note in particular that this is trivially true when γ is in the trivial coset given by upper triangular matrices, since both sides of the equation vanish.

By the fact that ψ is a multiplier system for Γ of weight 1/2, we immediately have for an element σ of Γ

$$P_\gamma|_{\psi,1/2}\sigma = P_{\gamma\sigma} \;, \text{ and } \; (J_{\gamma^{-1}\infty} S_\gamma)|_{\psi,1/2}\sigma = (J_{\sigma^{-1}\gamma^{-1}\infty} - J_{\sigma^{-1}\infty}) S_{\gamma\sigma} \;\;.$$

Upon summation over the representatives of the rectangle $(\Gamma_\infty\backslash\Gamma)_{<K}, K \to \infty$ and evoking Lemma 5.3, we obtain

$$R_{\Gamma,\rho}|_{\psi,1/2}\,\sigma = R_{\Gamma,\rho} - J_{\sigma^{-1}\infty} S_{\Gamma,\rho} \;. \tag{7.9}$$

Now it is an easy calculation to show that[2]

$$\left(R_{\Gamma,r} + J_\tau S_{\Gamma,\rho}\right)\Big|_{\psi,1/2}\sigma = R_{\Gamma,r} + J_\tau S_{\Gamma,\rho} \;,$$

which by definition (3.4) proves the claim. ☐

---

[2] In fact, one can show that the non-holomorphic completion $R_\Gamma + \tilde{S}_\Gamma$ also has a Rademacher form given by

$$\hat{R}_\Gamma(\tau) = \lim_{K\to\infty} \sum_{\gamma \in (\Gamma_\infty\backslash\Gamma)_{<K}} \epsilon(\gamma)^{-3}\,\mathrm{e}(-\tfrac{\gamma\tau}{8})\,\mathrm{com}(\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{1/4} \tag{7.10}$$

where $\mathrm{com}(\tau)$ is the *non-holomorphic completion factor* given in terms of the incomplete Gamma function, $\Gamma(\alpha, x) = \int_x^\infty t^{\alpha-1} e^t \mathrm{d}t$, by

$$\mathrm{com}(\tau) = 1 - \Gamma(1/2, \pi\Im(\tau)/2)/\sqrt{\pi} \;.$$

8 Coincidence

Recall from §4 that we write $R_{n|h}$ for $R_{\Gamma,\rho}$ when $\Gamma = \Gamma_0(n)$ and $\rho = \rho_{n|h}$, and similarly for $S_{n|h}$. In §7 we have established the transformation property of $R_{n|h}$ and $S_{n|h}$ under the group $\Gamma_0(n)$. In this section we will explicitly identify them. More precisely, we will first prove in §8.1 that

$$S_{n|h} = \begin{cases} \lambda_n \eta^3, \lambda_n \in \mathbb{C} & h = 1 \\ 0 & h > 1 \end{cases} \tag{8.1}$$

for the $(n,h) = (n_g, h_g)$ that appear in the cycle shapes of $[g] \subset M_{24}$, (cf. Table 1), and later in §8.2 complete the proof our main theorem 4.1 by showing $H_g = -2R_{n|h}$, assuming the result of §9.

8.1 Determining S

Let n and h be positive integers such that h divides both n and 24 and consider the function

$$F_{n|h}(\tau) = \frac{S_{n|h}(\tau)}{\eta(\tau)^3} \; .$$

Since $S_{n|h}$ has the same multiplier system as η^3 on $\Gamma_0(nh)$ and η does not vanish on the upper half-plane, $F_{n|h}$ is a modular function for $\Gamma_0(nh)$ that satisfies the transformation rule

$$F_{n|h}(\gamma\tau) = \rho(\gamma) F_{n|h}(\tau) \tag{8.2}$$

for $\gamma \in \Gamma_0(n)$ where $\rho = \rho_{n|h}$ is given explicitly by (2.5). In particular, $F_{n|h}$ induces a morphism, which we denote by $f_{n|h}$, of Riemann surfaces $X_0(nh) \to \mathbb{P}^1$ where $X_0(N)$ denotes the *modular curve* of level N and is formed by taking the quotient of the *extended upper half-plane*

$$\mathbb{H}^* = \mathbb{H} \cup \mathbb{Q} \cup \{\infty\}$$

by the action of the group $\Gamma_0(N)$. We will denote the corresponding canonical map by

$$\varphi_N : \mathbb{H}^* \to X_0(N) \; . \tag{8.3}$$

Note that there are no non-constant maps $X_0(nh) \to \mathbb{C}$, so either $F_{n|h}$ has a pole at some cusp of $\Gamma_0(nh)$, or $S_{n|h} = \lambda_{n|h}\eta^3$ for some $\lambda_{n|h} \in \mathbb{C}$. Of course, $S_{n|h}$ and η^3 have different automorphy for $\Gamma_0(n)$ when $h > 1$, and an identity $S_{n|h} = \lambda_{n|h}\eta^3$ implies that $\lambda_{n|h}$ and hence $S_{n|h}$ are identically zero. Our main strategy to show (8.1) is to show that $F_{n|h}$ is bounded at all cusps of $\Gamma_0(nh)$ for all the pairs (n,h) under consideration.

Since the Fourier expansion of both $S_{n|h}$ and η^3 around the infinite cusp starts with a term $q^{1/8}$(cf. (6.1)), we see that $F_{n|h}(\tau)$ is bounded as $\tau \to i\infty$ and can only have poles at the cusps of $\Gamma_0(nh)$ that are not represented by infinity. Furthermore, from the transformation (8.2) of $F_{n|h}$ under $\Gamma_0(n)$, we see that $f_{n|h}$ has a pole at a given cusp of $\Gamma_0(nh)$ if and only if it has a pole of the same order at every cusp that is an image of it under $\Gamma_0(n)$. Therefore, to prove (8.1) it is sufficient to show that $F_{n|h}$ are bounded at all cusps of $\Gamma_0(n)$ other than the infinite cusp.

In order to analyse the behaviour of $F_{n|h}$ at the cusp representative $\kappa \in \mathbb{Q}$, as before we will now consider its transformation under a given scaling element (cf. (7.3))

$$\tilde{\sigma} = \sigma \begin{pmatrix} \sqrt{u} & 0 \\ 0 & 1/\sqrt{u} \end{pmatrix} \begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix} \quad , \quad \sigma \in \mathrm{SL}_2(\mathbb{Z}) \; , \; \beta \in \mathbb{R}$$

n	1	2	3	4	5	6	7	8	10	11	12	14	15	21	23
cusps	/	0	0	$0,\frac{1}{2}$	0	$0,\frac{1}{2},\frac{1}{3}$	0	$0,\frac{1}{2},\frac{1}{4}$	$0,\frac{1}{2},\frac{1}{5}$	0	$0,\frac{1}{2},\frac{1}{3},\frac{1}{4},\frac{1}{6}$	$0,\frac{1}{2},\frac{1}{7}$	$0,\frac{1}{3},\frac{1}{5}$	$0,\frac{1}{3},\frac{1}{7}$	0
widths	/	2	3	4,1	5	6,3,2	7	8,2,1	10,5,2	11	12,3,4,3,1	14,7,2	15,5,3	21,7,3	23

Table 3: In this table we list the cusps other than the one at $i\infty$, which has width 1, of the groups $\Gamma_0(n)$ for $n = n_g$ in Table 1. Note that, in these cases we have an extra (non-infinite) cusp, represented by $\frac{1}{q}$, for every divisor q of n, and its width is given by the smallest positive integer v such that $n|qv^2$. Moreover, the corresponding multiplier $\rho(\sigma T^v \sigma^{-1}) = \mathrm{e}(\frac{m}{h})$ is given by $m = \frac{q^2 v}{n}(1+qv) \bmod h$.

for $\Gamma_0(nh)$ at $\kappa = \tilde{\sigma}\infty$:

$$F^{(\kappa)}_{n|h}(\tau) = F_{n|h}(\tilde{\sigma}\tau) = \frac{S_{n|h}(\tilde{\sigma}\tau)}{\eta^3(\tilde{\sigma}\tau)} = \frac{S^{(\kappa)}_{n|h}(\tau)}{\eta^3(u(\tau+\beta))} \ . \tag{8.4}$$

When $\tilde{\sigma}$ normalises $\Gamma_0(nh)$, $F^{(\kappa)}_{n|h}(\tau)$ again defines a modular function for $\Gamma_0(nh)$. The order of poles or zeros of the function $F^{(\kappa)}_{n|h}(\tau)$ at $\tau \to i\infty$ gives the order of poles or zeros of the function $f_{n|h} : X_0(nh) \to \mathbb{P}^1$ at the point x given by the image of the κ under the canonical map φ_{nh}.

In the proofs, we will be especially interested in the scaling elements that are elements of the so-called Atkin-Lehner involutions W_u, which are defined for every exact divisor u of n as the set of matrices of the form

$$\frac{1}{\sqrt{u}}\begin{pmatrix} au & b \\ cn & du \end{pmatrix} \quad , \quad a,b,c,d \in \mathbb{Z}$$

with determinant 1. We say u is an exact divisor of n if $(n/u, u) = 1$. An important element of W_n is the *Fricke involution*, given by

$$w_n = \begin{pmatrix} 0 & -1/\sqrt{n} \\ \sqrt{n} & 0 \end{pmatrix} \ . \tag{8.5}$$

From the expansion of $S^{(\kappa)}_{n|h}(\tau)$ recorded in (7.5), we see that $F^{(\kappa)}_{n|h}(\tau)$ has the expansion

$$F^{(\kappa)}_{n|h}(\tau) = \sum_{k=0}^{\infty} C_{n|h}(k)\, q^{\ell + \frac{u}{v}k} \quad , \quad \ell = \tfrac{u}{v}\,\{\{\tfrac{m}{h} + \tfrac{v}{8}\}\} - \tfrac{u}{8} \ . \tag{8.6}$$

As before, u denotes the width of the cusp in $\Gamma_0(nh)$, v denotes the width of the cusp in $\Gamma_0(n)$, and $\mathrm{e}(\frac{m}{h}) = \rho(\sigma T^v \sigma^{-1})$ as defined in (7.2). Moreover, since $F^{(\kappa)}_{n|h}(\tau)$ is invariant under $\langle \pm T \rangle \subset \tilde{\sigma}^{-1}\Gamma_0(nh)\tilde{\sigma}$, its Fourier expansion can only involve integral powers of q and it follows immediately that

$$F^{(\kappa)}_{n|h}(\tau) = \mathcal{O}(q^{\ell}) \quad , \quad \ell \geq 1 + \lfloor -\tfrac{u}{8} \rfloor \quad , \quad \ell \in \mathbb{Z} \ . \tag{8.7}$$

More generally, from the above formula it is also clear that, to prove that $f_{n|h}$ is bounded at κ it is sufficient to prove that

$$\{\{\tfrac{m}{h} + \tfrac{v}{8}\}\} \geq \tfrac{v}{8} \ . \tag{8.8}$$

We shall first consider the cases $n \leq 8$ when there are no cusps of $\Gamma_0(n)$ with width larger than 8. For these cases we have the following Lemma:

Lemma 8.1. *Consider the group $\Gamma_0(n)$ with $1 \leq n \leq 8$ and multiplier $\rho_{n|h}$ defined in (2.5) with h dividing both n and 24. The pole-free condition (8.8) is satisfied for all cusps of $\Gamma_0(n)$ if and only if $(n,h) = (n_g, h_g)$ is one of the 13 pairs that correspond to the cycle shapes of M_{24}, as collected in Table 1.*

Proof. First consider the case $h = 1$. In this case, since there are no cusps with $v > 8$, we get from (8.7) that $f_{n|h}$ has no pole for all $1 \leq n \leq 8$, $h = 1$.

For $h > 1$, we need more refined information about the order of zeros of $S^{(\kappa)}_{n|h}$ to show that, for a given $n < 9$, among all the possible values of h that divide both n and 24, the condition (8.8) is satisfied if and only if $(n,h) = (n_g, h_g)$ is one of the 13 pairs that correspond to the cycle shapes of M_{24}.

For the cusp with a representative $1/q$ and width v, taking $\sigma = \left(\begin{smallmatrix} 1 & 1 \\ q & q+1 \end{smallmatrix}\right)$ we get

$$m = \tfrac{q^2 v}{n}(1 + qv) \mod h\ . \tag{8.9}$$

In particular, we have $m = q$ and $v = n/q$ if q is an exact divisor of n. For the zero cusp ($q = 1$, note that 0 and 1 are related by $T \in \Gamma_0(n)$), therefore, we need h to satisfy $\{\{\frac{1}{h} + \frac{n}{8}\}\} \geq \frac{n}{8}$. It is straightforward to check that this condition is satisfied if and only if $(n,h) = (n_g, h_g)$ is one of the 13 pairs that show up in Table 1.

It remains to be shown that this condition is also satisfied at cusps other than 0 or ∞. First we check that $\{\{\frac{q}{h} + \frac{n/q}{8}\}\} \geq \frac{n/q}{8}$ is indeed satisfied for $n = h = 6$, $q = 2$ and $q = 3$. Finally, for $n = 4$, we have $q = 2$, $v = 1$ and $m = 3$ and we need to check $\{\{\frac{3}{h} + \frac{1}{8}\}\} \geq \frac{1}{8}$, which is indeed the case for $h = 4$. ☐

Corollary 8.2. *For $(n,h) = (n_g, h_g)$ being one of the 13 pairs with $1 \leq n \leq 8$ that arise from in the cycle shapes of M_{24}, (cf. Table 1), we have $S_{n|1} = \lambda_n \eta^3$ and $S_{n|h} = 0$ for $h > 1$.*

For $n > 8$, a direct proof via (8.8) is less straightforward and instead we would like to use arguments involving the topology of $X_0(n)$. When $X_0(nh)$ has genus one, we have the following two lemmas:

Lemma 8.3. *If $n \in \{11, 14, 15\}$ then $S_{n|1} = \lambda_n \eta^3$ for some $\lambda_n \in \mathbb{C}$.*

Proof. For these values of n there is just one cusp of $\Gamma_0(n)$ represented by 0 which has width $v = n > 8$. Hence, from (8.7) we see that the function $F^{(\kappa=0)}_{n|1}$ either has a simple pole at 0 or is a constant. Suppose the former were true, then $f_{n|1}$ defines a degree one function from $X_0(n)$ to $\mathbb{P}^1$, implying that $X_0(n)$ has genus zero as a Riemann surface. For $n \in \{11, 14, 15\}$ however, the genus of $X_0(n)$ is one, so we conclude that $f_{n|1}$ is constant in these cases.

☐

Lemma 8.4. *Suppose that $n \in \{10, 12\}$ and $h = 2$. Then $S_{n|h} = 0$.*

Proof. The only cusp of $\Gamma_0(20)$ that has width greater than 8 is that represented by 0, and similarly for $\Gamma_0(24)$, so in either case the only possible pole of $f_{n|h}$ is at the image under $\varphi_{nh} : \mathbb{H}^* \to X_0(nh)$ of the zero cusp. The degree of the pole, if the pole exists, is given by (8.6) with $2v = u = 2n$ and $m = 1$ equals 1, and so must be 1. In this case $f_{n|h} : X_0(nh) \to \mathbb{P}^1$ is a degree one map, implying that $X_0(nh)$ has genus zero. But this is not the case for $nh = 20$ or $nh = 24$. We conclude that $f_{n|h}$ has no poles and is thus constant. The claim follows.

☐

For the remaining three classes with $(n,h) = (23,1), (21,3), (12,12)$, the modular curves $X = X_0(nh)$ have higher genera and we will use the Riemann-Roch theorem:

$$\dim K_X(D) = \dim \Omega_X(D) + \deg(D) + 1 - \text{genus}(X) \tag{8.10}$$

to gain control over the allowed properties of the function $f_{n|h}$. Here D denotes a divisor on the Riemann surface X, $K_X(D)$ denotes the vector space of meromorphic functions f with the divisor (f) given by its zeros and poles satisfying $(f)+D \geq 0$, and $\Omega_X(D)$ denotes the space of holomorphic differentials ω on X satisfying $(\omega) - D \geq 0$.

Lemma 8.5. *If* $n = 23$ *then* $S_{n|1} = \lambda_n \eta^3$ *for some* $\lambda_n \in \mathbb{C}$.

Proof. The only cusp of $\Gamma_0(23)$ with width larger than 8 is the one with width 23 represented by 0, and hence the function $f_{23|1}$ can possibly have a pole only at $x \in X$ for x the image of 0 under φ_{23} (cf. (8.3)). More specifically, from (8.7) we see that $f_{23|1}$ is in the vector space $K_X(D)$ for $D = 2x$. Since the genus of $X_0(23)$ is 2, according to the Riemann-Roch formula (8.10) we have $\dim K_X(D) = 1 + \dim \Omega_X(D)$. We would like to prove the claim by showing that $\dim \Omega_X(D) = 0$ and hence $\dim K_X(D) = 1$, and therefore a function in $X(D)$ must be a constant function.

To show there is no holomorphic differential with a double zero at x, let us consider first the divisor $D' = x$. We know that $K_{D'}(X) \cong \mathbb{C}$, or else there would be a meromorphic function on X with a simple pole at x and no other poles, hence an isomorphism between X and $\mathbb{P}^1$, which is impossible given that the genus of X is 2. From this we conclude from the Riemann-Roch formula that $\dim \Omega_X(D') = \dim K_{D'}(X) = 1$ and there is a one-dimensional space of holomorphic differentials ω with $(\omega) - x \geq 0$. Now such a holomorphic differential is given by the weight 2 cusp form $\eta^2(\tau)\eta^2(23\tau)$, which is a holomorphic differential with a simple zero at x and a simple zero at the image of the infinite cusp under the canonical map $\mathbb{H}^* \to X_0(23)$ and no other zeros. From this we conclude $\dim \Omega_X(D) = 0$ and hence $\dim K_X(D) = 1$. This completes the proof. □

Lemma 8.6. *Suppose that* $n = 21$ *and* $h = 3$. *Then* $S_{n|h} = 0$.

Proof. For $n = 21$, by direct calculation one can check that the only cusp for which (8.8) does not hold is the cusp represented by 0. It corresponds to a cusp with width 63 of $\Gamma_0(63)$ and there are no other cusps of $\Gamma_0(63)$ at which $f_{21|3}$ can have a pole. Moreover, from (8.6) for the zero cusp, with

$$\tfrac{63}{21}\{\{\tfrac{21}{8} + \tfrac{1}{3}\}\} - \tfrac{63}{8} = -5$$

equation (8.6) shows that $f_{n|h}$ is in $K_D(X = X_0(63))$ with $D = 5x$, $x = \varphi_{63}(0)$.

The genus of $X_0(63)$ is 5 so according to the Riemann–Roch theorem (cf. (8.10)) we have $\dim K_X(D) = \dim \Omega_X(D) + 1$, where $\Omega_X(D)$ denotes the space of holomorphic differentials on X vanishing to order at least 5 at x. We claim that $\dim \Omega_X(D) = 0$. To show this, suppose $g \in S_2(\Gamma_0(63))$ corresponds to an element of Ω_X with a zero of order 5 at x. Since the Fricke involution w_{63} normalises $\Gamma_0(63)$, it induces a linear automorphism of $S_2(\Gamma_0(63))$. Then $g|_{1,2}\sigma$ is an element of $S_2(\Gamma_0(63))$ that is $\mathcal{O}(q^6)$ as $\tau \to i\infty$. By inspection there is no such cusp form of weight 2 for $\Gamma_0(63)$. We conclude that $\dim K_X(D) = 1$. Since $K_X(D)$ includes constant functions, our $f_{n|h}$ is constant, and the desired result follows.

□

Lemma 8.7. *Suppose that* $n = h = 12$. *Then* $S_{n|h} = 0$.

Proof. The group $\Gamma_0(nh) = \Gamma_0(144)$ has 9 cusps with widths exceeding 8: there are four with of width 9, having representatives 1/4, 3/4, 1/8 and 1/16, there are three of width 16, having representatives 1/3, 2/3 and 1/9, and there is one of width 36, with representative 1/2, and one of width 144, with representative 0. The four cusps of width 9 fuse under the action of $\Gamma_0(n) = \Gamma_0(12)$, as do the three cusps of width 16.

First we would like to see at which of these cusps of $\Gamma_0(144)$ the function $f_{n|h}$ could possibly have a pole. From the above data, we only need to look at the cusps of $\Gamma_0(12)$. From the formula (8.9) we see that $f_{n|h}$ is either constant or has a pole at the image of the zero cusp, as the pole-free condition (8.8) is satisfied at the all other cusps of $\Gamma_0(12)$. Moreover, putting $v = h = 12$, $m = 1$, $u = 144$ in the equation (8.6), we see that $f_{n|h}$ can only have a pole of order 11 if it is not a constant.

To show that a pole of order 11 cannot happen, first we will compute $\dim K_X(D) = 2$ for $X = X_0(144)$ and $D = 11x$ with $x = \varphi_{144}(0)$. The genus of $X_0(144)$ is 13 so according to the Riemann–Roch theorem (cf. (8.10)) we have $\dim K_X(D) = \dim \Omega_X(D) - 1$ where $\Omega_X(D)$ denotes the space of holomorphic differentials on X vanishing to order at least 11 at x. As in the proof of Lemma 8.6 we observe that elements of $\Omega_X(D)$ are in correspondence with cusp forms of weight 2 on $\Gamma_0(144)$ that are $\mathcal{O}(q^{12})$ as $\tau \to i\infty$. By inspection there is a three dimensional space of such cusp forms so $\dim K_X(D) = 2$.

Next set $D' = 10x$. We claim that then $K_X(D) = K_X(D')$. For certainly $K_X(D')$ is a subspace of $K_X(D)$ and their dimensions coincide since the Riemann–Roch theorem implies $\dim K_X(D') = \dim \Omega_X(D') - 2$ and $\dim \Omega_X(D') = 4$ by inspection of $S_2(\Gamma_0(144))$. We conclude that if $f_{n|h}$ is in $K_X(D)$ then it is also in $K_X(D')$ and then we must have $C_{n|h}(k = 0) = 0$ in (8.6), so that $f_{n|h}$ has no poles at any cusp and is therefore constant. This completes the proof. ☐

Remark. It is fascinating that the space $S_{3/2,\epsilon^3}(\Gamma_0(n))$ of cusp forms of weight 3/2 on $\Gamma_0(n)$ with multiplier system coinciding with that of η^3 is one-dimensional and spanned by η^3, whenever n is the order of an element of M_{23}. This is demonstrated by the above Lemmas taken together, while the same is certainly not true for a generic positive integer n.

For $n = 9$ and $n = 10$, for instance, it's possible that $F_{n|1} = S_{n|1}/\eta^3$ could define a degree one map $X_0(n) \to \mathbb{P}^1$, but this is no contradiction since $X_0(n)$ has genus zero for $n = 9$ and $n = 10$. Indeed, numerical approximations suggest that $S_{9|1}(\tau) = \eta(\tau)^3 + 3\eta(9\tau)^3$ and

$$S_{10|1}(\tau) = C\left(2\eta(\tau)^3 + 7\frac{\eta(2\tau)\eta(10\tau)^3}{\eta(5\tau)}\right)$$

for some $C \in \mathbb{C}$. Observe that the functions $\eta(\tau)^3/\eta(9\tau)^3$ and $\eta(\tau)^3\eta(5\tau)/\eta(2\tau)\eta(10\tau)^3$ are hauptmoduln for $\Gamma_0(9)$ and $\Gamma_0(10)$, respectively, and so $S_{3/2,\epsilon^3}(\Gamma_0(n))$ is not one dimensional for $n = 9$ or $n = 10$. Indeed, there are no M_{24} classes corresponding to $(n, h) = (9, 1)$ or $(10, 1)$.

Also in the case that $h > 1$, it is extremely non-trivial that for all the pairs (n, h) arising from M_{24}, just the correct combinations of genus, cusp widths and multipliers conspire to force the vanishing of $S_{n|h}$.

8.2 Determining R

First we will establish the identity $H_g = -2R_{n|1}$, for $n = n_g$ and for those g with $h_g = 1$. Recall from the discussion in §2 that these are the M_{24} classes whose action on the natural permutation representation has at least one fixed point (the M_{23} classes). To do this, we consider the function

$$G_{n|1} = \eta^3 \Big(\chi(g)\, R_{n|1} - \lambda_n H_g \Big) \tag{8.11}$$

with g being an M_{24} class with $n_g|h_g = n|1$. By construction, it has $G_{n|1} = (\chi(g) + 2\lambda_n) + \mathcal{O}(q)$ near the infinite cusp.

In §3 we saw that H_g is a weight 1/2 mock modular form for $\Gamma_0(n)$ with shadow $\chi(g)\eta^3$ and the same multiplier as η^{-3}. On the other hand, in §7 we have proven that the Rademacher sums $R_{n|1}$ are also weight 1/2 mock modular forms for $\Gamma_0(n)$ with the same multiplier. Moreover, it has as its shadow $S_{n|1}$, which was proven to be given by $\lambda_n \eta^3$ for some $\lambda_n \in \mathbb{C}$ in the previous subsection. Taken together, we see that the function $G_{n|1} : \mathbb{H}^* \to \mathbb{P}^1$ is a weight 2 modular form of $\Gamma_0(n)$ with trivial multiplier.

Using the properties of such weight 2 modular forms, we will be able to show that $G_{n|1} = 0$ for the values of n of interest to us. In particular, we have $\chi(g) + 2\lambda_n = 0$ as the constant term in the expansion near the infinite cusp. Since $\chi(g) \neq 0$ when $h_g = 1$, this implies $H_g = -2R_{n|1}$ for $g \in M_{24}$ with $h_g = 1$.

Lemma 8.8. *Let g be the identity element of M_{24} and set $n = n_g = 1$ and $h = h_g = 1$. Then $H = H_g = -2R_{n|h}$.*

Proof. From the above discussion we know the function

$$G_{n|1} = \eta^3 \left(24 R_{n|1} - \lambda_n H_g \right)$$

is a modular form of weight 2 for $\mathrm{SL}_2(\mathbb{Z})$ with trivial multiplier. There are no non-zero modular forms of weight 2 for $\mathrm{SL}_2(\mathbb{Z})$ so $G_{n|1}$ vanishes identically and by the above argument this proves the lemma. ☐

To prove $G_{n|1} = 0$ for $n > 1$ we need to study its behaviour near the other cusp representatives of $\Gamma_0(n)$. For a cusp $\kappa = \sigma\infty$, $\sigma \in \mathrm{SL}_2(\mathbb{Z})$, with width v in $\Gamma_0(n)$, we shall again consider its transformation under a scaling element $\tilde{\sigma}$ (cf. (7.3))

$$G^{(\kappa)}_{n|1}(\tau) = G_{n|1}\big|_{1,2} \sigma \left(v(\tau + \beta) \right) .$$

To be more precise, we would like to know the form of the Fourier expansion of $G^{(\kappa)}_{n|1}(\tau)$. As will be shown explicitly in Appendix E, we have

$$G^{(\kappa)}_{n|1}(\tau) = \mathcal{O}(q^{v/8+\Delta})$$

as $\tau \to i\infty$ with $\Delta \geq 0$, which corresponds to the fact that both $R_{n|1}$ and H_g have no pole at any cusp other than the infinite cusp. By construction, $G^{(\kappa)}_{n|1}$ is invariant under $\tau \to \tau + 1$ and hence the above argument shows

$$G^{(\kappa)}_{n|1}(\tau) = \mathcal{O}(q^{\lceil v/8 \rceil}) , \tag{8.12}$$

where the ceiling function $\lceil x \rceil$ gives the smallest integer not less than $x \in \mathbb{R}$.

Lemma 8.9. *Suppose that $g \in M_{24}$ has prime order $n = n_g$ and $h = h_g = 1$. Then $H_g = -2R_{n|h}$.*

Proof. The primes dividing the order of M_{24} are exactly those primes p for which $(p+1)|24$ so $n \in \{2,3,5,7,11,23\}$. For these n, the only non-infinite cusp of $\Gamma_0(n)$ is the one represented by 0, with width n. Take the Fricke involution w_n to be the scaling element. From (8.12) we conclude that $G^{(\kappa=0)}_{n|1}$ is $\mathcal{O}(q)$ for $n \in \{2,3,5,7\}$ and $\mathcal{O}(q^2)$ for $n = 11$ and $\mathcal{O}(q^3)$ for $n = 23$.

Since the Fricke involution w_n for $\Gamma_0(n)$ normalises $\Gamma_0(n)$, $G^{(\kappa=0)}_{n|1}$ also belongs to $M_2(\Gamma_0(n))$. The space $M_2(\Gamma_0(n))$ of such weight 2 modular forms contains the space $S_2(\Gamma_0(n))$ of weight 2 cusp forms. The dimension of the latter is given by the genus of the modular curve $X_0(n)$. A complement in the former to the latter is spanned by $\{\Lambda_m,\ m>1,\ m|n\}$ with

$$\begin{aligned}\Lambda_m(\tau) = m\,q\frac{d}{dq}\log(\eta(n\tau)/\eta(\tau)) &= \frac{m}{24}\Big(m\,E_2(m\tau) - E_2(\tau)\Big)\\ &= \frac{m(m-1)}{24} + \sum_{k=1}^{\infty} m\sigma(k)(mq^{mk} - q^k)\end{aligned} \tag{8.13}$$

where $\sigma(k)$ is the sum of the divisors of k and E_2 is the holomorphic quasi-modular Eisenstein series of weight 2.

When n is prime, obviously the complement in $M_2(\Gamma_0(n))$ to $S_2(\Gamma_0(n))$ is one-dimensional and spanned by Λ_n. Since the genus of $X_0(n)$ is zero for $n \in \{2,3,5,7\}$, the space $M_2(\Gamma_0(n))$ is one-dimensional and spanned by Λ_n. Now, with Λ_n having non-vanishing constant term, the statement $G^{(\kappa=0)}_{n|1}(\tau) = \mathcal{O}(q)$ implies that $G^{(\kappa=0)}_{n|1}(\tau)$ vanishes identically.

If $n = 11$ then $M_2(\Gamma_0(n))$ is two dimensional, spanned by Λ_n and the cusp form $\eta_g(\tau) = \eta(\tau)^2\eta(11\tau)^2$, and since Λ_n and η_g have non-vanishing coefficients of q^0 and q^1, respectively, we conclude that $G^{(\kappa=0)}_{n|1}(\tau) = \mathcal{O}(q^2)$ implies the vanishing of $G^{(\kappa=0)}_{n|1}$ in this case also. When $n = 23$, the space $M_2(\Gamma_0(n))$ is spanned by Λ_n, a cusp form $\phi_{23,1} = \eta_g(\tau)^2 = \eta(\tau)^2\eta(23\tau)^2$ and a further cusp form

$$\phi_{23,2}(\tau) = \frac{\eta(\tau)^3\eta(23\tau)^3}{\eta(2\tau)\eta(46\tau)} + 4\eta(\tau)\eta(2\tau)\eta(23\tau)\eta(46\tau) + 4\eta(2\tau)^2\eta(46\tau)^2. \tag{8.14}$$

Inspecting the Fourier expansions of Λ_n, $\phi_{23,1}$ and $\phi_{23,2}$ we see that there is no non-zero linear combination that is $\mathcal{O}(q^3)$. We conclude that $G^{(\kappa=0)}_{n|1}(\tau)$ vanishes identically for all the values of n in question. So $G_{n|1}$ also vanishes and the desired result follows. ☐

Lemma 8.10. *Suppose that $g \in M_{24}$ has order $n = n_g$ a product of two distinct primes and $h = h_g = 1$. Then $H_g = -2R_{n|h}$.*

Proof. According to Table 1 the values of n in question are 6, 14 and 15. From the discussion before (8.13) we see that the complement to $S_2(\Gamma_0(n))$ in $M_2(\Gamma_0(n))$ is three-dimensional and spanned by the weight two modular forms $\Lambda_{e_1}, \Lambda_{e_2}$ and Λ_{e_3}, where $e_1 < e_2 < e_3 = n$ are the three (exact) divisors of n that are larger than 1. Therefore, we have

$$G_{n|1} = \alpha_1\Lambda_{e_1} + \alpha_2\Lambda_{e_2} + \alpha_3\Lambda_{e_3} + \phi$$

with $\phi \in S_2(\Gamma_0(n))$. In other words, ϕ vanishes when $n = 6$ and is a multiple of η_g when $n = 14, 15$, in accordance with the fact that the genera of $X_0(6)$, $X_0(14)$, $X_0(15)$ are 0, 1, 1, respectively.

For each e_i there is a corresponding cusp of $\Gamma_0(n)$ with width e_i, which is represented by $\kappa_i = \frac{e_i}{n}$. These are the only cusps of $\Gamma_0(n)$ apart from the infinite cusp, as listed in Table 3. As discussed before (cf. (8.12)), the corresponding function $G^{(\kappa_i)}_{n|1}(\tau)$ has the asymptotic behaviour

$$G^{(\kappa_i)}_{n|1}(\tau) = \mathcal{O}(q^{\Delta+\frac{e_i}{8}}) \ .$$

Consider a scaling element which is an Atkin-Lehner involution w_{e_i} with $\kappa_i = w_{e_i}\infty$ (note that it is different from the Fricke involution when $e_i \neq n$). With help from the identity

$$\tfrac{1}{e}\Lambda_e|_{1,2}w_f = \tfrac{1}{e*f}\Lambda_{e*f} - \tfrac{1}{f}\Lambda_f \tag{8.15}$$

where $e*f = ef/(e,f)^2$, we obtain three equations on α_i from the vanishing of the constant terms in $G^{(\kappa_i)}_{n|1}(\tau)$. Solving the resulting linear system we quickly deduce that $\alpha_1 = \alpha_2 = \alpha_3 = 0$ and hence $G_{n|1}(\tau)$ is given by the cusp form ϕ of $\Gamma_0(n)$.

Since $X_0(6)$ has genus zero we conclude that $G_{n|1}(\tau) = 0$ for $n = 6$. For $n = 14, 15$, to prove that $G_{n|1}(\tau) = \phi = 0$ let us focus on the 0 cusp with width n. Take the scaling element to be the Fricke involution w_n. From the fact that the cusp form η_g is an eigenfunction (with eigenvalue -1) of w_n we get $G^{(\kappa)}_{n|1}(\tau) = C\eta_g = -Cq + \mathcal{O}(q^2)$ for some $C \in \mathbb{C}$. But from (8.12) we see that $G^{(\kappa)}_{n|1}(\tau) = \mathcal{O}(q^2)$ for $v = n = 14, 15$. Hence we conclude $G_{n|1} = C = 0$. □

Lemma 8.11. *Suppose that $g \in M_{24}$ is such that $h = h_g = 1$ and $n = n_g$ is 4 or 8. Then $H_g = -2R_{n|h}$.*

Proof. If $n = 4$ then $\dim M_2(\Gamma_0(n)) = 2$ and $M_2(\Gamma_0(n))$ is spanned by the modular forms Λ_2 and Λ_4 (cf. (8.13)). If $n = 8$ then $\dim M_2(\Gamma_0(n)) = 3$ and $M_2(\Gamma_0(n))$ is spanned by Λ_2, Λ_4 and Λ_8. In both cases $\dim S_2(\Gamma_0(n)) = 0$.

Consider the case that $n = 4$, where we have $G_{n|1} = \alpha\Lambda_2 + \beta\Lambda_4$. There are two non-infinite cusps: one represented by 0 with width 4 and the other represented by 1/2 with width 1. Taking as their scaling elements w_4 and $T^{1/2}w_4$ respectively, we get two equations on the coefficients α, β from the requirement that both $G^{(\kappa=0)}_{n|1}$ and $G^{(\kappa=1/2)}_{n|1}$ are $\mathcal{O}(q)$, which force both α and β and hence $G_{n|1}$ to vanish. In arriving at these equations, we have used the identity (8.15) and

$$E_2(\tau + 1/2) = -E_2(\tau) + 6E_2(2\tau) - 4E_2(4\tau) \ .$$

The argument for $n = 8$ is very similar. We have $F = \alpha\Lambda_2 + \beta\Lambda_4 + \gamma\Lambda_8$ for some $\alpha, \beta, \gamma \in \mathbb{C}$. We may take 0, 1/2 and 1/4 as representatives for the three non-infinite cusps of $\Gamma_0(8)$. We may take w_8, $T^{1/2}w_8$ and $w_8T^{1/2}w_8$, respectively, as scaling elements for these cusp representatives. Using the identities given above we compute expressions for the constant term at each non-infinite cusp as linear equations in α, β and γ. From the vanishing of each constant term we deduce that $\alpha = \beta = \gamma = 0$ and hence $G_{n|1} = 0$ also. Then the required identity $H_g = -2R_{n|h}$ follows as before. □

The above Lemmas 8.8-8.11, when taken together, show that $H_g = -2R_{n_g|1}$ for $g \in M_{24}$ with $h_g = 1$ Now we will continue to show the identity for the remaining M_{24} classes with $n_g = n$, $h_g = h > 1$.

Lemma 8.12. *Let g be an element of M_{24} that has $h_g > 1$ and $n_g \neq 21$. Then $H_g = -2R_{n|h}$.*

Proof. To prove the identity $-2R_{n|h} = H_g$ for the remaining classes $[g]$ with $h_g > 1$, we consider the following function

$$K_{n|h} = \frac{R_{n|h}}{H_g} \ .$$

Since both $R_{n|h}$ and $H_g = -\tilde{T}_g/\eta^3$ are known to be weight 1/2 modular forms which transform with a multiplier $\rho_{n|h}$ on $\Gamma_0(n)$, we conclude that $K_{n|h}$ is a modular function on $\Gamma_0(n)$. As in the previous subsection, such a modular function has to be either constant or have a pole. For $g \in M_{24}$ with $h_g > 1$ and $n_g \neq 21$, the McKay–Thompson series H_g are all given by certain η-quotients (cf. Table 2). Since η does not have a zero in $\mathbb{H}$, we only have to check that $K_{n|h}$ has no pole at any cusp of $\Gamma_0(n)$. At the infinite cusp we have $R_{n|h} = q^{-1/8} + \mathcal{O}(q^{7/8})$ and $H_g = -2q^{-1/8} + \mathcal{O}(q^{7/8})$ and hence $K_{n|h}$ has no pole at the infinite cusp.

To see that it is also bounded near a non-infinite cusp $\kappa = \sigma\infty = \tilde{\sigma}\infty$, $\sigma \in \mathrm{SL}_2(\mathbb{Z})$, with a scaling element $\tilde{\sigma}$, we consider the function

$$G^{(\kappa)}_{n|h} = G^{(\kappa)}_{n|h}\big(\sigma\left(v(\tau+\beta)\right)\big) = \frac{R^{(\kappa)}_{n|h}(\tau)}{\tilde{T}_g/\eta^3|_{\epsilon^{-3},1/2}\,\sigma(v(\tau+\beta))}$$

where $R^{(\kappa)}_{n|h}(\tau)$ has been shown in Appendix E to have an expansion

$$R^{(\kappa)}_{n|h}(\tau) = R^{(\kappa)}_{n|h}\big|_{\epsilon^3,1/2}\sigma\left(v(\tau+\beta)\right) = \sum_{k=1}^{\infty} c^{(\kappa)}_{\Gamma,\rho}(k-\nu)\,\mathrm{e}(\tau(k-\nu)) \ , \tag{8.16}$$

where $\nu = \{\{\frac{m}{h} + \frac{v}{8}\}\}$ as explained in (7.5). With direct calculation, one can check that also

$$\frac{\tilde{T}_g}{\eta^3}\big|_{\epsilon^{-3},1/2}\,\sigma(v(\tau+\beta)) = a_g\, q^{1-\nu} + \mathcal{O}(q^{2-\nu})$$

at every non-infinite cusp κ of $\Gamma_0(n)$ with some $a_g \in \mathbb{C}$, $a_g \neq 0$.

This shows that $K_{n|h}$ is a modular function with no pole and hence constant, which is $-1/2$ from its value at the infinite cusp.

□

Lemma 8.13. *Suppose that $g \in M_{24}$ is such that $n = n_g = 21$ and $h = h_g = 3$. Then $H_g = -2R_{n|h}$.*

Proof. Set $\phi_{21,1}(\tau) = \eta(7\tau)^3/\eta(3\tau)\eta(21\tau)$ and $\phi_{21,2}(\tau) = \eta(\tau)^3/\eta(3\tau)^2$. Then both $\phi_{21,1}$ and $\phi_{21,2}$ are (meromorphic) modular forms of weight 1/2 for $\Gamma_0(21)$ with multiplier system $\rho\epsilon^{-3}$ where $\rho = \rho_{21|3}$, so that

$$G = \frac{AR_{n|h} + B\phi_{21,1}}{\phi_{21,2}} \quad , \quad A, B \in \mathbb{C}$$

is a modular function for $\Gamma_0(21)$ whose only poles are at the non-infinite cusps of $\Gamma_0(21)$. Since $R_{n|h}, \phi_{21,2}, \phi_{21,2}$ all have the expansion $q^{-1/8} + \mathcal{O}(q^{7/8})$ near the infinite cusp, we see that G has no pole at the infinite cusp. For $e_{1,2,3}$ with $e_1 < e_2 < e_3 = 21$ the exact divisors of 21 that are larger than 1 let w_{e_i} be an element of the Atkin–Lehner involution of $\Gamma_0(21)$ associated to e_i. Then the elements w_{e_i} furnish scaling elements at the respective representatives $\kappa_i = w_{e_i}\infty$ for the three non-infinite cusps of $\Gamma_0(21)$, represented by $\frac{e_i}{n}$ having width e_i. Using the fact that the slash operator $|_{1/2,\epsilon} w_{e_i}$ maps $\eta(e_j\tau)$ to $\eta(e_i * e_j\tau)$ (up to a non-vanishing scale factor), we see that the function $G^{(\kappa_i)} = G(w_{e_i}\tau)$ remains bounded as $\tau \to i\infty$ except possibly in the case that $e_3 = 21$, in which case we have

$$G^{(\kappa=0)}(\tau) = G(w_{21}\tau) = \left(A' R^{(\kappa=0)}_{n|h}(\tau) + B' \frac{\eta(3\tau)^3}{\eta(7\tau)\eta(\tau)} \right) \frac{\eta(7\tau)^2}{\eta(21\tau)^3} \,,\ A', B' \in \mathbb{C}.$$

From (8.16) we see that $G^{(\kappa=0)}(\tau)$ has a Fourier expansion of the form $Cq^{-2} + \mathcal{O}(q^{-1})$. Setting $D = 2x$ where x is the image of $w_{21}\infty = 0$ under the natural map $\varphi_{21} : \mathbb{H}^* \to X = X_0(21)$ we see that f must belong to the space $K_X(D)$ of meromorphic functions on $X = X_0(21)$ having a pole of order at most 2 at x and no other poles. The genus of $X_0(21)$ is 1 so according to the Riemann–Roch theorem (cf. (8.10)) we have $\dim K_X(D) = \dim \Omega_X(D) + 2$ where $\Omega_X(D)$ denotes the space of holomorphic differentials on X vanishing to order at least 2 at x. The full space Ω_X of holomorphic differentials on X is in correspondence with $S_2(\Gamma_0(21))$, and this one-dimensional space is in turn spanned by the L-series for the elliptic curve $y^2 + xy = x^3 + x$. This cusp form has a Fourier expansion of the form $q + \mathcal{O}(q^2)$ and is an eigenform for w_{21} so we conclude that it does not belong to $\Omega_X(D)$, and thus $\dim \Omega_X(D) = 0$ and $\dim K_X(D) = 2$. Now $K_X(D)$ includes constant functions on X and it also includes the non-constant function $\phi_{21,1}/\phi_{21,2}$, so it is spanned by these functions, and we may conclude that $R_{n|h} = C_1\phi_{21,1} + C_2\phi_{21,2}$ for some $C_1, C_2 \in \mathbb{C}$. By comparison of polar terms in the Fourier expansions of $R_{n|h}$, $\phi_{21,1}$ and $\phi_{21,2}$ we have $C_1 + C_2 = 1$. Now consider the expansion of $R_{n|h}$ at the cusp represented by $w_7\infty$ (which is also represented by 1/3). We have $(\phi_{21,1}|w_7)(\tau) = D_1 q^{-21/24} + \mathcal{O}(q^{3/24})$ and $(\phi_{21,2}|w_7)(\tau) = D_2 q^{-21/24} + \mathcal{O}(q^{3/24})$ and the fact that $R_{n|h}$ has no poles away from the infinite cusp implies that $C_1 + 7C_2 = 0$. We conclude that $6R_{n|h} = 7\phi_{21,1} - \phi_{21,2}$. From Table 2 we have the explicit expression $3H_g = \phi_{21,2} - 7\phi_{21,1}$. This proves the lemma. □

9 Spectral Theory

In this section we would like to demonstrate the convergence of the Selberg–Kloosterman zeta function $Z_{0,k}(s, \rho\epsilon^{-3})$, defined in (5.6) and (5.7), of $\Gamma = \Gamma_0(n)$ for n a positive integer. As before, we take $\psi = \epsilon^{-3}\rho_{n|h}$ for some h dividing both 24 and n (cf. (2.5)). Combined with the discussions in §5 and §6, Theorem 9.1 completes the proof of the convergence of the Rademacher sum (4.8).

Let w be a positive real number and let ψ be a multiplier system of weight w for Γ. We say a function $g(z)$ on $\mathbb{H}$ is *automorphic for* Γ *of weight* w *with respect to* ψ if

$$\psi(\gamma) g(\gamma z) \exp(iw \arg(\operatorname{jac}(\gamma, z))/2) = g(z)$$

for all $\gamma \in \Gamma$, where $\arg(\cdot)$ is defined so that $-\pi < \arg(z) \leq \pi$ for $z \neq 0$, and write $\mathcal{H}_{\psi,w}$ for the Hilbert space consisting of those automorphic functions which also satisfy the growth condition

$$\iint_{\Gamma\backslash\mathbb{H}} |g(\tau)|^2 \frac{\mathrm{d}x\mathrm{d}y}{y^2} < \infty$$

where $x = \Re(\tau)$ and $y = \Im(\tau)$ for $z \in \mathbb{H}$. We consider the operator Δ_w on $\mathcal{H}_{\psi,w}$ given by

$$\Delta_w = y^2 \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) - iwy \frac{\partial}{\partial x}.$$

According to [33] if ψ is non-trivial on every parabolic subgroup of Γ then Δ_w has a discrete spectrum of eigenfunctions in $\mathcal{H}_{\psi,w}$ and there exists a complete orthonormal system $\{u_j(z)\}$ of eigenfunctions satisfying

$$\Delta_w u_j(z) + \lambda_j u_j(z) = 0$$

for a set $\{\lambda_j\}$ of eigenvalues which are all real. (Roelcke proves in [34] that Δ_w has a unique self-adjoint extension to $\mathcal{H}_{\psi,w}$.) Further, the λ_j are all positive except possibly for a finite number which are of the form

$$(w/2 - l)(1 + l - w/2) \tag{9.1}$$

where l is a non-negative integer less than $w/2$. If there is an eigenvalue of the form (9.1) then, negative or otherwise, it's multiplicity is equal to the dimension of the space $S_{w-2l}(\Gamma, \psi)$ of (holomorphic) cusp forms for Γ of weight $w - 2l$ with respect to ψ.

By the trivial estimate $|S(m, k, c, \psi)| < c$ the series (5.7) defining the Selberg–Kloosterman zeta function $Z_{m,k}(s, \psi)$ converges absolutely and locally uniformly for $\Re(s) > 1$ and thus defines a holomorphic function in this domain. Selberg demonstrates in [33] that this function admits an analytic continuation to a function meromorphic in the entire s-plane that is holomorphic for $\Re(s) > 1/2$ except possibly for a finite number of simple poles lying on the real segment $1/2 < s < 1$. Poles on this segment can only occur at points of the form $1/2 + \sqrt{1/4 - \lambda_j}$ where $0 < \lambda_j < 1/4$ and λ_j is an eigenvalue of Δ_w, and such a pole does occur if λ_j is not of the form (9.1) and the coefficients of $\mathrm{e}((m - \alpha)x)$ and $\mathrm{e}((n - \alpha)x)$ in the Fourier expansion (with respect to x) of the corresponding eigenfunction $u_j(z)$ are both non-zero. If λ_j is of the form (9.1) with $l = \lfloor w/2 \rfloor$ then there is a pole at $s = 1 + \lfloor w/2 \rfloor - k/2$ just in the case that there is a cusp form $f(\tau) \in S_{w-2\lfloor w/2 \rfloor}(\Gamma, \psi)$ for which the coefficients of $q^{m-\alpha}$ and $q^{n-\alpha}$ (in its Fourier expansion with respect to τ) are both non-zero.

For the case of relevance for us we have $w = 1/2$ and so all the λ_j will be positive. Roelcke proves in [34] that the minimal value of a λ_j is $3/16$ in case $w = 1/2$ (see [35] for a nice exposition) so we conclude that there are no poles for $Z_{0,k}(s, \rho\epsilon^{-3})$ in $\Re(s) > 3/4$. The only possible value for l in (9.1) is $l = 0$ so that the occurrence of a pole at $s = 1 + \lfloor w/2 \rfloor - w/2 = 3/4$ depends upon the existence of a cusp form $f \in S_w(\Gamma, \psi)$ for which the coefficients of $q^{0-\alpha}$ and $q^{k-\alpha}$ are both non-zero. We have $-\alpha = -1/8$ so there is no such cusp form and we conclude that $Z_{0,k}(s, \rho\epsilon^{-3})$ is in fact analytic in $\Re(s) > 3/4 - \delta$ for some $\delta > 0$ and has finitely many simple poles lying on the line segment $1/2 < s < 3/4$.

It remains to show that the value of the analytically continued function $Z_{0,k}(s, \rho\epsilon^{-3})$ at $s = 3/4$ is indeed the sum

$$\sum_{c>0} \frac{S(0, k, c, \rho\epsilon^{-3})}{c^{3/2}}$$

that we expect it is. To establish this we adopt the approach presented in §2 of [36][3] which is an adaptation of a technique commonly used in proving the prime number theorem (cf. [38]). (For a very crisp application of what is essentially the same argument, see the proof of Theorem 2 in [32].) Fix a group Γ, a multiplier $\psi = \rho\epsilon^{-3}$, and an integer k. We will write $Z(s) = Z_{0,k}(s, \rho\epsilon^{-3})$ to ease notation. Define

$$\Sigma(x) = \sum_{0<c<x} \frac{S(0, k, c, \rho\epsilon^{-3})}{c^{3/2}}$$

---

[3] If you consult this reference please see also §II of [37] for some important corrections.

for $x > 0$. We require to show that $\lim_{x\to\infty} \Sigma(x) = Z(3/4)$. Observe that for $a > 0$ and $x \neq c$ the integral

$$\frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} \left(\frac{x}{c}\right)^t \frac{\mathrm{d}t}{t}$$

is 1 or 0 according as $x > c$ or $x < c$. Consequently we may rewrite $\Sigma(x)$ as

$$\Sigma(x) = \sum_{c>0} \frac{S(0,k,c,\rho\epsilon^{-3})}{c^{3/2}} \frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} \left(\frac{x}{c}\right)^t \frac{\mathrm{d}t}{t}$$

for non-integral values of x. Choose $\varepsilon > 0$ and set $a = 1/2 + \varepsilon$ so that $Z(t/2 + 3/4)$ converges absolutely for $\Re(t) = a$. For $T > 0$ define $\Sigma_T(x)$ by setting

$$\Sigma_T(x) = \frac{1}{2\pi i}\int_{a-iT}^{a+iT} Z(t/2+3/4)x^t \frac{\mathrm{d}t}{t}.$$

Then for the difference $\Sigma(x) - \Sigma_T(x)$ we have the upper bound

$$|\Sigma(x) - \Sigma_T(x)| < x^a \sum_{c>0} c^{-1-\varepsilon} \min\left(1, \frac{1}{T|\log(x/c)|}\right) \tag{9.2}$$

thanks to the following estimate, which may be found in §17 of [38].

$$\frac{1}{2\pi}\left|\int_{a-i\infty}^{a+i\infty} \left(\frac{x}{c}\right)^t \frac{\mathrm{d}t}{t} - \int_{a-iT}^{a+iT} \left(\frac{x}{c}\right)^t \frac{\mathrm{d}t}{t}\right| < \left(\frac{x}{c}\right)^a \min\left(1, \frac{1}{T|\log(x/c)|}\right)$$

Following exactly the argument of the last paragraph of p.171 of [36] we can replace the summation in (9.2) with the more explicit bound

$$|\Sigma(x) - \Sigma_T(x)| < K\frac{x^{1/2}}{T}(x^\varepsilon + \log x) \tag{9.3}$$

where K is some constant (that does not depend on our choice of n).

Consider now the integral

$$\frac{1}{2\pi i}\int_C Z(t/2+3/4)\, x^t\, \frac{\mathrm{d}t}{t}$$

where $C = C_0 + C_1 + C_2 + C_3$ is the positively oriented rectangle with corners $(\pm 1/2) + \varepsilon \pm iT$. For concreteness let us say that C_0 is the right most vertical component and C_1 is the upper most horizontal component, &c. Then the contribution of C_0 is exactly $\Sigma_T(x)$. We denote the contribution of C_i by I_i for $i \neq 0$. By the residue theorem we have

$$\Sigma_T(x) + I_1 + I_2 + I_3 = Z(3/4) + \sum_{j\in J} \varrho_j x^{2s_j - 3/2} \tag{9.4}$$

where $\{s_j\}_{j\in J}$ is an enumeration of the (finite) set of poles of $Z(s)$ in the interval $1/2+\varepsilon/2 < s < 3/4$ (we may choose $\varepsilon > 0$ so that $s = 1/2 + \varepsilon/2$ is not a pole) and ϱ_j is the residue of $Z(s)$ at $s = s_j$ divided by $2s_j - 3/2$.

We wish to determine what happens when $x \to \infty$ in (9.4). Observe, for a start, that the sum over j vanishes in this limit since $2s_j < 3/2$ for all $j \in J$. We claim that the integrals I_i also vanish in this limit. To estimate the I_i we utilise the growth condition

$$|Z(s)| = O\left(\frac{|s|^{1/2}}{\Re(s) - 1/2}\right)$$

as $|\Im(s)| \to \infty$, valid for $\Re(s) > 1/2$. Such a result was first established by Goldfeld–Sarnak in [32]. We have applied the generalisation found in [39] due to Pribitkin. Since $Z(s)$ converges absolutely for $\Re(s) > 1$ we have that $|Z(t/2 + 3/4)| = \mathcal{O}(1)$ as $|\Im(t)| \to \infty$ when $\Re(t) = 1/2 + \varepsilon$, and thus an application of the Phragmén–Lindelöf theorem (cf. [40], Thm. 14) yields

$$|Z(t/2 + 3/4)| < K_\varepsilon \, |\Im(t)|^{1/4 - \Re(t)/2 + \varepsilon/2} \tag{9.5}$$

for all t such that $-1/2 + \varepsilon \leq \Re(t) \leq 1/2 + \varepsilon$ and $|\Im(t)|$ is sufficiently large, for some constant K_ε depending only on Γ, $\psi = \rho\epsilon^{-3}$, k and ε. Applying (9.5) to the integrals I_i we obtain that $I_2 = \mathcal{O}(T^{1/2}x^{-1/2+\varepsilon})$, and both I_1 and I_3 are $\mathcal{O}(T^{-1}x^{1/2+\varepsilon})$ so long as $T < x^2$. Setting $T = x^{2/3}$, letting $x \to \infty$ in (9.4) and applying (9.3) gives us the desired result: $\lim_{x\to\infty} \Sigma(x) = Z(3/4)$. In particular, we have the following theorem:

Theorem 9.1. *Let $\Gamma = \Gamma_0(n)$ for some positive integer n, let h be a divisor of* $\gcd(n, 24)$ *and set $\rho = \rho_{n|h}$. Then for any positive integer n the Selberg–Kloosterman zeta function $Z_{0,k}(s, \rho\epsilon^{-3})$ converges at $s = 3/4$.*

10 Conclusion and Discussion

To summarise, motivated by the AdS/CFT correspondence in physics, we propose to replace the genus zero property by the more general property of Rademacher summability as the organising principle of the modular properties of moonshine phenomena. In monstrous moonshine, where the McKay–Thompson series are modular functions, the latter coincides with the former and is hence automatically satisfied, as shown in [10]. The two conditions decouple in the case of the recently conjectured relation between mock modular forms and M_{24}: on the one hand, it is neither necessary nor sufficient that a group Γ have genus zero for it to arise as Γ_g for some g in M_{24}, and on the other hand, we verify the Rademacher summability property in Theorem 4.1. In view of the above, the Rademacher summability property may replace the genus zero property, and applies to both monstrous moonshine and M_{24}. This also suggests that AdS/CFT considerations will lead to further elucidation of the moonshine phenomena, and we expect the powerful Rademacher machinery to prove useful in further study of the connection between modular objects and finite groups in general.

This result raises many interesting physical questions. In particular, what do we know about the gravity duals, if they exist, of 2d CFTs with sporadic symmetries? Let us first concentrate on the sigma models with target spaces involving $K3$ surfaces, as they are relevant for the structures studied in the present paper. Recall that one of the best known examples of the AdS/CFT correspondence conjectures that the two-dimensional CFT describing the Higgs branch of the system of Q_1 D1-branes bound to Q_5 D5-branes wrapping a $K3$ surface is dual to the type IIB string theory in the background $AdS_3 \times S^3 \times K3(Q)$ [12]. Here the radius of curvature of AdS_3 and S^3 is given by $(Q_1Q_5)^{1/4}$ in the six dimensional unit, and $K3(Q)$ is the "attractor K3" whose moduli are partially fixed by the requirement of minimising the BPS mass of the given charges, or equivalently, by the so-called attractor mechanism of supergravity. Note that not all $K3$ surfaces can be such an attractor $K3$ for a given set of charges. On the conformal field theory side, the Higgs branch is described by a 2d $\mathcal{N} = (4,4)$ SCFT with central charge $c = 6k$, $k = Q_1Q_5 + 1$, which is a deformation of the sigma model on the symmetric product S^kK3, as can be most easily understood by going to the D0-D4 duality frame [41].

This AdS/CFT dictionary makes it clear that a "semi-classical-like" AdS gravity description is only guaranteed to exist when we take the central charge $c = 6k$, or equivalently the AdS radius, to be very large. For this reason, it is in fact surprising that the Rademacher machinery works so well when applied to the partition functions for the $K3$ sigma model with $k = 1$, as demonstrated in the present paper. Two comments on this issue are in order here. First, analogous Rademacher formulas also exist for the symmetric product sigma model with higher k and we plan to report on this in more detail in the future [27]. In other words, the Rademacher machinery also works when we have very strong reasons to expect them to work. Second, recently there has been important progress in developing the localisation techniques for computing gravity path integrals (see, for example, [42]), and we have seen that in some cases the highly quantum path integral actually localises into the same form as if coming from a weakly coupled, semi-classical gravitational theory. For instance, very recently the Rademacher sum for the modular form $1/\eta(\tau)^{24}$, which is the partition function of a CFT with central charge as small as $c = 24$, has been reproduced from a localised gravity path integral [43]. This is very surprising since the corresponding black holes have zero macroscopic entropy (that is, the Bekenstein-Hawking entropy grows only linearly with the charges) and hence a priori we have no reason to expect the gravity path integral to take this "semi-classical" form. These results show that the Rademacher formulas are not really the monopoly of a large radius, semi-classical gravity description, although the former is most easily motivated in the semi-classical limit as we reviewed in §1, and suggests that it is not unlikely that a localisation calculation could similarly explain the Rademacher sum formulas derived in the present paper from a gravity point of view. In the case of monstrous moonshine, on the other hand, the question of whether a semi-classical theory of gravity dual to the moonshine module conformal field theories, or possibly their higher central charge cousins, is an interesting open puzzle [44].

We end with a few more comments concerning the Rademacher formulas studied in this paper. Firstly, it is remarkable that the Rademacher sums with such a simple polar term $-2q^{-1/8}$ compute not only the M_{24}-modules underlying the massive states in the $K3$ CFT but also the twisted Euler characteristics of $K3$ surfaces. The latter statement comes from the fact that the Rademacher machinery automatically computes the shadows of the resulting mock modular forms, which are in this case given by the twisted $K3$ Euler characteristics multiplied by the modular form $\eta(\tau)^3$. Finally, we would like to mention that none of the twisted elliptic genera which arise from the extra, non-M_{24} symmetries discussed in [45] lead to (mock) modular forms admitting analogous Rademacher sum expressions. Another related but logically independent observation is the following. If we were to twist the partition function counting the 1/4-BPS index of type II theory compactified on $K3 \times T^2$ with one of these non-M_{24} symmetries, the resulting candidate 4d twisted partition function would have a system of poles and zeros that is more intricate and complicated than the ones coming from twisting with M_{24} symmetries. This adds to the distinction between the M_{24} symmetries and the extra non-M_{24} discrete symmetries which are present in, for instance, the Gepner models, whose role in moonshine is still obscure.

Acknowledgements

We thank Atish Dabholkar, Rajesh Gopakumar, Tom Hartman, Özlem Imamoglu, Jan Manschot, Shiraz Minwalla, Ashoke Sen, Edward Witten, and Don Zagier for many useful discussions, and we thank Amanda Folsom and Wladimir de Azevedo Pribitkin for communication related to convergence. We also thank Alejandra Castro, Thomas Creutzig, Igor Frenkel, Christoph Keller, Alex Maloney, Andy Strominger and S.T. Yau for earlier discussions on related topics. M.C. would like to thank the Institute for Advanced Study for hospitality during part of this work, and the organisers and participants of "the School and Conference on Modular Forms and mock Modular Forms and their Applications in Arithmetic, Geometry and Physics" for stimulating discussions. The research of M.C. is supported in part by NSF grant DMS-0854971.

A Dedekind Eta Function

The *Dedekind eta function*, denoted $\eta(\tau)$, is a holomorphic function on the upper half-plane defined by the infinite product

$$\eta(\tau) = q^{1/24} \prod_{n\geq 1}(1-q^n)$$

where $q = \mathrm{e}(\tau) = e^{2\pi i\tau}$. It is a modular form of weight $1/2$ for the modular group $\mathrm{SL}_2(\mathbb{Z})$ with multiplier $\epsilon : \mathrm{SL}_2(\mathbb{Z}) \to \mathbb{C}^*$, which means that

$$\epsilon(\gamma)\eta(\gamma\tau)\,\mathrm{jac}(\gamma,\tau)^{1/4} = \eta(\tau)$$

for all $\gamma = \left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, where $\mathrm{jac}(\gamma,\tau) = (c\tau+d)^{-2}$. The *multiplier system* ϵ may be described explicitly as

$$\epsilon\begin{pmatrix} a & b \\ c & d\end{pmatrix} = \begin{cases} \mathrm{e}(-b/24), & c=0,\ d=1 \\ \mathrm{e}(-(a+d)/24c + s(d,c)/2 + 1/8), & c>0 \end{cases} \tag{A.6}$$

where $s(d,c) = \sum_{m=1}^{c-1}(d/c)((md/c))$ and $((x))$ is 0 for $x \in \mathbb{Z}$ and $x - \lfloor x \rfloor - 1/2$ otherwise. We can deduce the values $\epsilon(a,b,c,d)$ for $c < 0$, or for $c = 0$ and $d = -1$, by observing that $\epsilon(-\gamma) = \epsilon(\gamma)\,\mathrm{e}(1/4)$ for $\gamma \in \mathrm{SL}_2(\mathbb{Z})$.

Let T denote the element of $\mathrm{SL}_2(\mathbb{Z})$ such that $\mathrm{tr}(T) = 2$ and $T\tau = \tau + 1$ for $\tau \in \mathbb{H}$. Observe that

$$\epsilon(T^m\gamma) = \epsilon(\gamma T^m) = \mathrm{e}(-m/24)\epsilon(\gamma)$$

for $m \in \mathbb{Z}$.

B Bessel Function

The *Bessel function of the first kind*, denoted $J_\alpha(x)$, may be defined by the series expression

$$J_\alpha(x) = \sum_{m\geq 0}(-1)^m \frac{(x/2)^{2m+\alpha}}{\Gamma(m+1+\alpha)m!}. \tag{B.1}$$

The function $J_\alpha(x)$ is asymptotic to $e^x \cos(x - \alpha\pi/4 - \pi/4)/\sqrt{2\pi x}$ for x large, and in the special case that $\alpha = 1/2$ this fact is borne out by the identity

$$J_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sin(x). \tag{B.2}$$

The *modified Bessel function of the first kind*, denoted $I_\alpha(x)$, may be defined by the series expression

$$I_\alpha(x) = \sum_{m\geq 0}\frac{(x/2)^{2m+\alpha}}{\Gamma(m+1+\alpha)m!}. \tag{B.3}$$

The function $I_\alpha(x)$ is asymptotic to $e^x/\sqrt{2\pi x}$ for x large, for any α. In the special case that $\alpha = 1/2$ this fact is borne out by the identity

$$I_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sinh(x). \tag{B.4}$$

As x approaches 0 the functions $J_{1/2}(x)$ and $I_{1/2}(x)$ both tend towards $(x/2)^\alpha/\Gamma(1+\alpha)$. Since $\Gamma(3/2)=\sqrt{\pi}/2$ we have

$$J_{1/2}(x)\approx\sqrt{\frac{2x}{\pi}},\ I_{1/2}(x)\approx\sqrt{\frac{2x}{\pi}} \tag{B.5}$$

as $x\to 0$ in the special case that $\alpha=1/2$.

C Lipschitz Summation

The *Lipschitz summation formula* is the identity

$$\frac{(-2\pi i)^s}{\Gamma(s)}\sum_{k=1}^{\infty}(k-\alpha)^{s-1}\,\mathrm{e}((k-\alpha)\tau)=\sum_{\ell\in\mathbb{Z}}\mathrm{e}(\alpha\ell)(\tau+\ell)^{-s}, \tag{C.1}$$

valid for $\Re(s)>1$ and $0\le\alpha<1$, where $\mathrm{e}(x)=e^{2\pi ix}$. A nice proof of this using Poisson summation appears in [46]. Observe that both sides of (C.1) converge absolutely and uniformly in τ on compact subsets of $\mathbb{H}$.

For applications to Rademacher sums of weight less than 1 we require an extension of (C.1) to $s=1$. Absolute convergence on the right hand side breaks down at this point but we can get by with the following useful analogue.

Lemma C.1. *For $0<\alpha<1$ we have*

$$\sum_{k=1}^{\infty}\mathrm{e}((k-\alpha)\tau)=\sum_{-K<\ell<K}\mathrm{e}(\alpha\ell)(-2\pi i)^{-1}(\tau+\ell)^{-1}+E_K(\tau) \tag{C.2}$$

where $E_K(\tau)=\mathcal{O}(1/K^2)$, locally uniformly for $\tau\in\mathbb{H}$.

Proof. Our proof follows that of Lemma 4.1 in [31]. For $\tau\in\mathbb{H}$ define a function $f(z)$ by setting

$$f(z)=\frac{1}{2\pi iz}\frac{\mathrm{e}(\alpha(z-\tau))}{(\mathrm{e}(z-\tau)-1)}. \tag{C.3}$$

Then f has poles at $\tau+n$ for each $n\in\mathbb{Z}$ and also has a pole at $z=0$. The residue at $z=0$ is

$$\frac{1}{2\pi i}\frac{\mathrm{e}(-\alpha\tau)}{\mathrm{e}(-\tau)-1}=\frac{1}{2\pi i}\sum_{k=1}^{\infty}\mathrm{e}((k-\alpha)\tau),$$

which is $(2\pi i)^{-1}$ times the left hand side of (C.2), and the residue at $z=\tau+n$ is $\mathrm{e}(\alpha n)(2\pi i)^{-2}(\tau+n)^{-1}$. Suppose $\tau=\sigma+it$. Let K be a positive integer and let $\mathcal{C}$ be the positively oriented boundary of a rectangle with corners $\sigma\pm(K+1/2)\pm iL$ where $L>\Im(\tau)=t$ and $K+1/2>\Re(\tau)=\sigma$. Then by the residue theorem

$$\int_{\mathcal{C}}f(z)\mathrm{d}z=\sum_{k=1}^{\infty}\mathrm{e}((k-\alpha)\tau)-\sum_{-K<\ell<K}\mathrm{e}(\alpha\ell)(-2\pi i)^{-1}(\tau+\ell)^{-1}.$$

On the other hand, the integrals over the horizontal portions of $\mathcal{C}$ tend to 0 as $L \to \infty$ since $|f(z)|$ decays exponentially as $\Im(z) \to \infty$. The residues are independent of L for L sufficiently large so taking the limit as $L \to \infty$ we obtain

$$\sum_{k=1}^{\infty} \mathrm{e}((k-\alpha)\tau) - \sum_{-K<\ell<K} \mathrm{e}(\alpha\ell)(-2\pi i)^{-1}(\tau+\ell)^{-1} = E_K(\tau)$$

where $E_K(\tau)$ is the limit as $L \to \infty$ of the contributions to $\int_{\mathcal{C}} f(z)\mathrm{d}z$ coming from the vertical portions of $\mathcal{C}$.

$$E_K(\tau) = i\int_{-\infty}^{\infty} (f(\sigma+K+1/2+iy) - f(\sigma-K-1/2+iy))\mathrm{d}y$$

For convenience set $Q = K + 1/2$. After replacing y with $y + t$ we obtain

$$E_K(\tau) = -\frac{1}{2\pi}\int_{-\infty}^{\infty} \left(\frac{\mathrm{e}(\alpha Q)}{Q+iy+\tau} - \frac{\mathrm{e}(-\alpha Q)}{-Q+iy+\tau}\right)\frac{\mathrm{e}(\alpha iy)}{1+\mathrm{e}(iy)}\mathrm{d}y \tag{C.4}$$

since $\mathrm{e}(Q) = \mathrm{e}(-Q) = -1$ for K an integer. Observe that the integrand in (C.4) is bounded by C/Q^2, for some constant C, and decays exponentially as $y \to \pm\infty$ for $0 < \alpha < 1$. Also, the constant C holds locally uniformly in τ. We conclude that $E_K(\tau) = \mathcal{O}(1/K^2)$ locally uniformly in τ, as required. □

For $\alpha = 0$ we have the identity

$$\lim_{K\to\infty} \sum_{\ell=-K}^{K} \frac{1}{\tau+\ell} = \pi\cot\pi\tau = -i\pi\big(1 + 2\sum_{m=1}^{\infty} q^m\big)\ .$$

D Some Details on Convergence

In this appendix we will give the steps leading to the expression (5.5), whose convergence we demonstrated in the main text. Using the explicit definition (4.5), (5.1) and again split the sum over d into a double sum, we obtain

$$\begin{aligned}
&\lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} R^0_\gamma(\tau) \\
&= \mathrm{e}(\tfrac{1}{8}) \sum_{\substack{0<c<K\\ n|c}} c^{-3/2} \sum_{\substack{-K^2<d<K^2\\ (c,d)=1}} \mathrm{e}(-\tfrac{\gamma\infty}{8})\psi(\gamma)(\tau+d/c)^{-1} \\
&= \mathrm{e}(\tfrac{1}{8}) \sum_{\substack{0<c<K\\ n|c}} c^{-3/2} \sum_{\substack{0\le d<c\\ (c,d)=1}} \mathrm{e}(-\tfrac{\gamma\infty}{8})\psi(\gamma) \sum_{\substack{\ell\in\mathbb{Z}\\ |d+\ell c|<K^2}} \frac{\mathrm{e}(\frac{\ell}{8})}{(\tau+d/c+\ell)}\ ,
\end{aligned} \tag{D.1}$$

where we have used $\psi(\gamma T) = \mathrm{e}(\frac{1}{8})\psi(\gamma)$ (see Appendix A) in deriving the last line.

Consider the following two expressions

$$\sum_{\substack{\ell\in\mathbb{Z}\\ |d+\ell c|<K^2}} \mathrm{e}(\tfrac{\ell}{8})(\tau+d/c+\ell)^{-1},\quad \sum_{\substack{\ell\in\mathbb{Z}\\ |\ell|<K^2/c}} \mathrm{e}(\tfrac{\ell}{8})(\tau+d/c+\ell)^{-1}\ , \tag{D.2}$$

we will now argue that we can use either of the two in the limit $K \to \infty$.

The left most of (D.2) may include a term where $d + \ell c = x - K^2$ for at most one $0 \leq x < d$ and this will not appear in the right hand expression, and the right most of (D.2) may include a term where $d + \ell c = x + K^2$ for at most one $0 < x \leq d$ and these will not appear in the left hand expression. We conclude that the difference is $\mathcal{O}(c/K^2)$ for sufficiently large K, uniformly in τ, and since $\sum_{0<c<K} c^{1/2}$ is $\mathcal{O}(K^{3/2})$ we have

$$\sum_{\substack{0<c<K\\ n|c}} c^{1/2} \sum_{\substack{0\leq d<c\\ (c,d)=1}} \mathcal{O}(c/K^2) = \mathcal{O}(1/K^{1/2})$$

which vanishes as $K \to \infty$. Therefore we have

$$\lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} R^0_\gamma(\tau) = \mathrm{e}(\tfrac{1}{8}) \lim_{K\to\infty} \sum_{\substack{0<c<K\\ n|c}} c^{-3/2} \sum_{\substack{0\leq d<c\\ (c,d)=1}} \mathrm{e}(-\tfrac{\gamma\infty}{8})\psi(\gamma) \sum_{\substack{\ell\in\mathbb{Z}\\ |d|<K^2/c}} \frac{\mathrm{e}(\frac{\ell}{8})}{(\tau + d/c + \ell)} \ . \tag{D.3}$$

Upon applying the Lipschitz summation formula in the form of Lemma C.1 we obtain

$$\begin{aligned}\lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)^\times_{<K}} R^0_\gamma(\tau) &= 2\pi\, \mathrm{e}(-\tfrac{1}{8}) \lim_{K\to\infty} \sum_{\substack{0<c<K\\ n|c}} c^{-3/2} \sum_{\substack{0\leq d<c\\ (c,d)=1}} \mathrm{e}(-\tfrac{\gamma\infty}{8})\psi(\gamma)\\ &\times \Big(- E_{\lfloor K^2/c\rfloor}(\tau) + \sum_{k=1}^{\infty} \mathrm{e}((k-\tfrac{1}{8})(\tau + \tfrac{d}{c}))\Big) \ .\end{aligned}$$

For K large the error terms $E_{\lfloor K^2/c\rfloor}(\tau)$ are bounded by $E_K(\tau)$ and according to Lemma C.1 we have $E_K = \mathcal{O}(1/K^2)$. It follows that the term involving $-E_{\lfloor K^2/c\rfloor}(\tau)$ is $\mathcal{O}(1/K^{3/2})$ and thus tends to 0 as $K \to \infty$. Observe that the sum over k in the above formula is absolutely convergent, uniformly in τ on compact subsets of $\mathbb{H}$. Moving the summation over k past the others and using the explicit expressions for $\psi(\gamma)$, we readily obtain (5.5).

E Rademacher Sums at Other Cusps

To identify $R_{\Gamma,\rho}$, we need to study its behaviour at the other cusps of $\Gamma = \Gamma_0(n)$. Focusing on a given cusp representative $\kappa = \sigma\infty$, $\sigma \in \mathrm{SL}_2(\mathbb{Z})$, with width v in $\Gamma_0(n)$, we need to study $R_{\Gamma,\rho}\big|_{\epsilon^{-3},1/2}\sigma$. For this purpose, let us introduce

$$R'_\gamma = \epsilon^{-3}(\gamma)\, e(-\tfrac{\gamma\tau}{8})\, \mathrm{reg}(\gamma,\tau)\, \mathrm{jac}^{1/4}(\gamma,\tau) \tag{E.1}$$

$$S'_\gamma = \epsilon^{3}(\gamma)\, e(\tfrac{\gamma\tau}{8})\, \mathrm{jac}^{3/4}(\gamma,\tau) \tag{E.2}$$

analogous to the definitions in §5, so that

$$R_{\Gamma,\rho} = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \rho(\gamma)\, R'_\gamma \quad , \quad S_{\Gamma,\rho} = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}} \rho^{-1}(\gamma)\, S'_\gamma \ .$$

A straightforward calculation similar to the one in §7 shows

$$\begin{aligned} R'_\gamma\big|_{\epsilon^{-3},1/2}\sigma &= R'_{\gamma\sigma} + cJ_{\sigma^{-1}\infty}S'_{\gamma\sigma} \quad , \quad c = -\frac{\mathrm{e}(\frac{1}{4})}{\sqrt{8}}\\ S'_\gamma\big|_{\epsilon^{3},3/2}\sigma &= S'_{\gamma\sigma} \ . \end{aligned} \tag{E.3}$$

Using $S_{n|1} = \lambda_n \eta^3$ and $S_{n|h} = 0$ for $h > 1$ as shown in §8.1, we get

$$R_{n|1}|_{\epsilon^{-3},1/2}\sigma = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} R'_\gamma + c\lambda_n J_{\sigma^{-1}\infty}\eta^3 \tag{E.4}$$

$$R_{n|h}|_{\epsilon^{-3},1/2}\sigma = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} \rho(\gamma\sigma^{-1})\, R'_\gamma \quad \text{for} \ \ h > 1\ . \tag{E.5}$$

Splitting the sum into a sum over the double coset space $(\Gamma_\infty\backslash\Gamma)_{<K}\sigma/\Gamma^v_\infty$ and applying the Lipschitz summation formula as before, we obtain that the Fourier expansion of the above sum is

$$\lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} \rho(\gamma\sigma^{-1})\, R'_\gamma = \sum_{k=1}^{\infty} c_k\ \mathrm{e}((k-\nu)\tfrac{\tau}{v})\ . \tag{E.6}$$

As before we have $0 < \nu \leq 1$ given by $\nu = \{\{\frac{m}{h} + \frac{v}{8}\}\}$, where $\rho(\sigma T^v \sigma^{-1}) = \mathrm{e}(\frac{m}{h})$ (cf. (7.5)).

In particular, for $h = 1$ we have

$$\lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} R'_\gamma = \sum_{k=1}^{\infty} c_k\ \mathrm{e}(\,(k - \{\{\tfrac{v}{8}\}\}\,)\tfrac{\tau}{v})\ . \tag{E.7}$$

Using Lemma 8.8 and equation (3.6), we can rewrite the function $G_{n|1}$ as

$$G_{n|1} = \lambda_n \tilde{T}_g + \chi(g)\eta^3\big(R_{n|1} + \tfrac{\lambda_n}{12} R_{1|1}\big)\ .$$

From (E.4) we deduce that

$$\big(R_{n|1} + \tfrac{\lambda_n}{12} R_{1|1}\big)\big|_{\epsilon^{-3},1/2}\sigma = \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} R'_\gamma + \tfrac{\lambda_n}{12} R_{1|1}$$

and hence

$$G_{n|1}\big|_{1,2}\,\sigma = \eta^3 \left(-\lambda_n \left(\frac{\chi(g)}{24} H - \frac{\tilde{T}_g|_{1,2}\,\sigma}{\eta^3} \right) + \chi(g) \lim_{K\to\infty} \sum_{\gamma\in(\Gamma_\infty\backslash\Gamma)_{<K}\sigma} R'_\gamma \right)\ .$$

One can check from the explicit expressions for $\tilde{T}_g$ that $\frac{\chi(g)}{24}H - \frac{\tilde{T}_g|_{1,2}\,\sigma}{\eta^3} = \mathcal{O}(1)$, so that the only pole of H_g is at the infinite cusp. Together with the (E.7) we obtain the expansion (8.12).

Abstract

We study the second quantized version of the twisted twining genera of generalized Mathieu moonshine, and prove that they give rise to Siegel modular forms with infinite product representations. Most of these forms are expected to have an interpretation as twisted partition functions counting 1/4 BPS dyons in type II superstring theory on K3$\times T^2$ or in heterotic CHL-models. We show that all these Siegel modular forms, independently of their possible physical interpretation, satisfy an "S-duality" transformation and a "wall-crossing formula". The latter reproduces all the eta-products of an older version of generalized Mathieu moonshine proposed by Mason in the '90s. Surprisingly, some of the Siegel modular forms we find coincide with the multiplicative (Borcherds) lifts of Jacobi forms in umbral moonshine.

1 Introduction and Summary

Mathieu moonshine [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16] and its generalized version [17, 18] pertain to the association of a class of weak Jacobi forms $\phi_{g,h}(\tau, z)$, called twisted twining genera, to each commuting pair of elements (g, h) in M_{24}. It has been verified that these functions satisfy all the requirements of Norton's generalized moonshine conjectures [19]; in particular they decompose into (projective) graded characters of the centralizer of g in M_{24}. Many of these Jacobi forms arise as supersymmetric indices in certain non-linear sigma models with target space K3; in particular, $\phi_{e,e}$ is the K3 elliptic genus. The obvious idea that M_{24} might be the symmetry group of some of these non-linear sigma models has been ruled out quite quickly [8, 10, 11] and the most recent works on the subject [20, 21, 22] seek for an explanation of Mathieu moonshine in the framework of K3 compactifications of full-fledged superstring theory rather than within conformal field theory.

In this paper we adopt a similar viewpoint, and construct the second-quantized[*] version $\Psi_{g,h}$ of the twisted twining genera. From a mathematical perspective, the functions $\Psi_{g,h}$ are obtained from the Jacobi forms $\phi_{g,h}$ via a certain twisted equivariant version of Borcherds multiplicative lift. Physically, many of these functions can be interpreted as twisted supersymmetric indices counting 1/4 BPS states in type II superstring theory compactified on K3$\times T^2$ and in CHL models [24, 25, 26, 27]. A similar construction for the twining genera of the ordinary Mathieu moonshine was first proposed by Cheng [2].

We show that these multiplicative lifts are Siegel modular forms, generalizing results for the case $(g, h) = (e, h)$ [2, 28, 29]. In some cases we can identify $\Psi_{g,h}$ with known Siegel modular forms which have previously appeared in the context of umbral moonshine [30]. Furthermore, they satisfy a "wall-crossing formula", which reproduces all of Mason's generalized eta-products $\eta_{g,h}$ for M_{24} [31, 32, 33, 34]. This therefore establishes the link between the two existing versions of generalized moonshine for M_{24}.

1.1 Background

The first hint of Mathieu moonshine was found by Eguchi, Ooguri and Tachikawa [1], who noticed a connection between the the elliptic genus of K3 and the largest Mathieu group M_{24}. The elliptic genus of K3 $\phi_{K3}(\tau, z)$ is the unique (up to normalization) weak Jacobi form of weight 0 and index 1 and it can be defined as a supersymmetric index of non-linear sigma models with target space K3. It therefore is natural to consider a decomposition of $\phi_{K3}(\tau, z)$ into characters of the $\mathcal{N} = 4$ superconformal algebra. The authors of [1] noticed that the coefficients in this decomposition are sums of dimensions of irreducible representations of M_{24}. This observation led to the Mathieu moonshine conjecture: for each conjugacy class $[g]$ of M_{24} there should exist a weak Jacobi form $\phi_g : \mathbb{H}\times\mathbb{C} \to \mathbb{C}$ such that the Fourier coefficients of ϕ_g are the characters of these M_{24}-representations evaluated at g. In particular, for the identity element e of M_{24}, $\phi_e(\tau, z)$ coincides with the elliptic genus of K3. In subsequent work [2, 3, 4, 5], all the functions ϕ_g, dubbed "twining elliptic genera", were found and substantial evidence was given for the validity of Mathieu moonshine, namely the existence of a graded M_{24}-module such that the ϕ_g's are its graded characters. This conjecture has now been proven rigorously by Gannon [12].

The story outlined above is of course in close analogy with Monstrous moonshine [35, 36, 37] which assigns modular functions $T_g : \mathbb{H} \to \mathbb{C}$ (McKay-Thompson series) with each conjugacy class $[g]$ of the Fischer-Griess Monster group $\mathbb{M}$, the largest of the finite sporadic simple groups. After the initial conjecture [35], Norton proposed his generalized Monstrous moonshine [19], which assigns modular functions $f(g, h; \tau)$ to each commuting pair $g, h \in \mathbb{M}$. For fixed $g \in \mathbb{M}$, these generalized moonshine functions should then have (possibly rational) Fourier coefficients that correspond to projective characters of the centralizer $C_{\mathbb{M}}(g) = \{k \in \mathbb{M} \,|\, gk = kg\}$. Dixon-Ginsparg-Harvey subsequently suggested that Norton's functions $f(g, h; \tau)$ naturally arise in string theory as the path integral on a torus $\mathbb{C}/(\mathbb{Z}+\tau\mathbb{Z})$ with boundary conditions twisted by (g, h) along the (a, b)-cycles. Although the full generalized Monstrous moonshine conjecture is still open, considerable progress has been made toward proving it [38, 39, 40, 41, 42, 43, 44].

---

[*] The terminology "second-quantized" originates in the work of Dijkgraaf, Moore, Verlinde, Verlinde [23].

In earlier work [17, 18], we gave substantial evidence that Norton's generalization also holds, with small modifications, for Mathieu moonshine. We found that for each commuting pair $g, h \in M_{24}$ there exists a weak Jacobi form $\phi_{g,h}(\tau, z)$, dubbed *twisted twining genus*, whose Fourier coefficients are characters of a projective representation of $C_{M_{24}}(g)$. Inspired by orbifolds of holomorphic CFT's [45, 46, 47, 48], we further showed that the modular properties of the functions $\phi_{g,h}$ are controlled by a cohomology class $[\alpha]$ in the third cohomology group $H^3(M_{24}, U(1))$, as was anticipated in [49] (see also [12]).

A different kind of generalized moonshine for M_{24} had in fact already been established in old work by Mason [31, 33, 34]. Mason associated to each commuting pair g, h in M_{24} a so called multiplicative eta product $\eta_{g,h}(\tau)$, based on the action of M_{24} on 24 chiral free bosons. This leads to the natural question: *Is there a relation between the recently discovered Mathieu moonshine, pertaining to weak Jacobi forms, and Mason's M_{24}-moonshine involving eta-products?*

For the special case of commuting pairs $(g, h) = (e, h)$, where e is the identity element of M_{24}, this was given an affirmative answer by Cheng in [2]. Cheng's idea was to generalize the known fact that the elliptic genus of K3, $\phi_e(\tau, z)$, exhibits an exponential Borcherds lift to the unique weight 10 Siegel modular form for $Sp(4; \mathbb{Z})$, referred to as the "Igusa cusp form" and commonly denoted by Φ_{10}. She proposed that to all twining genera $\phi_h(\tau, z)$ one should have a similar lift of the form

$$\Phi_h(\sigma, \tau, z) = pqy \prod_{(n,m,\ell)>0} \exp\left[- \sum_{k=1}^{\infty} \frac{c_{h^k}(4mn - \ell^2)}{k} (p^m q^n y^\ell)^k \right], \tag{1.1}$$

where $q = e^{2\pi i\tau}, y = e^{2\pi i z}, p = e^{2\pi i\sigma}$, and c_g denotes the Fourier coefficients of $\phi_g(\tau, z)$:

$$\phi_g(\tau, z) = \sum_{m\geq 0, \ell\in\mathbb{Z}} c_g(m, \ell) q^m y^\ell. \tag{1.2}$$

It was conjectured in [28] that Φ_h is automorphic with respect to a subgroup $\Gamma_h^{(2)}$ of $Sp(4; \mathbb{Z})$. This was then proven by Raum [29] for most of the conjugacy classes $[h] \subset M_{24}$.

A central point for us is that $\Phi_h(\sigma,\tau,z)$ has a double pole at $z=0$ and in the limit one finds

$$\lim_{z\to 0}\frac{\Phi_h(\sigma,\tau,z)}{(2\pi i z)^2}=\eta_h(\tau)\,\eta_h(\sigma), \tag{1.3}$$

where $\eta_h=\eta_{e,h}$ are the eta-products of Mason's M_{24}-moonshine [31]. Hence, the process of taking the multiplicative lift of ϕ_h followed by studying the limiting behavior as $z\to 0$ provides a link between the two moonshines.

1.2 Summary of results

In this paper we answer the question above in the general case of commuting pairs (g,h) in M_{24}. In other words, we establish a link between the generalized Mathieu moonshine proposed in [17, 18] and the generalized eta-products of Mason. To describe our results, we recall the notion of "second quantized elliptic genus" as defined in [23]. Suppose $\phi_X(\tau,z)$ is the elliptic genus of some Calabi-Yau manifold X. Then one defines the second quantized genus Ψ_X as the generating function of the elliptic genus ϕ_{S^nX} for the n:th symmetric product S^nX: $\Psi_X=\sum_{n\geq 0}p^n\phi_{S^nX}$. In [23], the following remarkable formula is proved

$$\Psi_X(\sigma,\tau,z)=\exp\Big[\sum_{n=1}^{\infty}p^nT_n\phi_X(\tau,z)\Big], \tag{1.4}$$

where $p=e^{2\pi i\sigma}$, and T_n is the standard Hecke operator acting on Jacobi forms. Subsequently, Gritsenko showed [50] that by multiplying the inverse Ψ_X^{-1} by a certain factor $A_X(\sigma,\tau,z)$ (the "Hodge anomaly") one obtains a Siegel modular form

$$\Phi_X(\sigma,\tau,z)=\frac{A_X(\sigma,\tau,z)}{\Psi_X(\sigma,\tau,z)}, \tag{1.5}$$

of weight $c_X(0,0)/2$ for a subgroup $\Gamma_X^{(2)}\subset Sp(4;\mathbb{Z})$, where $c_X(m,n)$ are the Fourier coefficients of ϕ_X.

Inspired by these results, we define for each commuting pair (g,h) in M_{24} the associated *second quantized twisted twining genus* $\Psi_{g,h}$ via a generalization of the formula (1.4):

$$\Psi_{g,h}(\sigma,\tau,z)=\exp\Big[\sum_{n=1}^{\infty}p^n\mathcal{T}_n^{\alpha}\phi_{g,h}(\tau,z)\Big], \tag{1.6}$$

where $\mathcal{T}_n^{\alpha}$ is now a certain twisted equivariant Hecke operator (for the precise definition see section (3.2)) which reduces to the T_n in (1.4) in the special case $(g,h)=(e,e)$. Notice that, when $g=e$, the presence of a non trivial 3-cocycle α governing the modular properties of the twisted twining genera can be safely ignored (see [17] and section 2.2). This leads to the simpler definition of the multiplicative lift adopted in [28]. However, for the general case considered in this paper, the technical subtleties associated with non-trivial 3-cocycles cannot be avoided.

Multiplying the second quantized twisted twining genera by a correction $A_{g,h}(\sigma,\tau,z)$ (see eq. (3.53) for the explicit form of $A_{g,h}$) we obtain a new class of functions

$$\Phi_{g,h}(\sigma,\tau,z)=\frac{A_{g,h}(\sigma,\tau,z)}{\Psi_{g,h}(\sigma,\tau,z)}, \tag{1.7}$$

and the main result of this paper is:

Theorem. *The functions $\Phi_{g,h}(\sigma,\tau,z)$ defined by (1.7) are meromorphic Siegel modular forms for certain discrete subgroups $\Gamma^{(2)}_{g,h}\subset Sp(4;\mathbb{R})$, such that $\Gamma^{(2)}_{g,h}\cap Sp(4,\mathbb{Z})$ is a congruence subgroup of $Sp(4,\mathbb{Z})$.*

For a more precise formulation, see Theorem 5.3 in section 5.2.

The most noticeable new automorphic property is the 'S-duality' transformation

$$\Phi_{g,h}(\sigma,\tau,z)=\Phi_{g,h'}(\frac{\tau}{N\lambda},N\lambda\sigma,z)\ , \tag{1.8}$$

where N is the order of g and λ is the length of the shortest cycle of g in the 24-dimensional permutation representation. Notice that $h,h'\in C_{M_{24}}(g)$ are not necessarily in the same conjugacy class. This is related with the 'relabeling' phenomenon described in [17]. In particular, as described in section 5.1.2, when g is an element of an M_{23} subgroup, then h' is the symmetry induced by h in the g-orbifold theory. We proved (1.8) for at least one commuting pair of generators (g,h) in each group $\langle g,h\rangle$, but we conjecture that similar relations hold for all commuting pairs.

In section 4 we prove the following "wall-crossing formula"

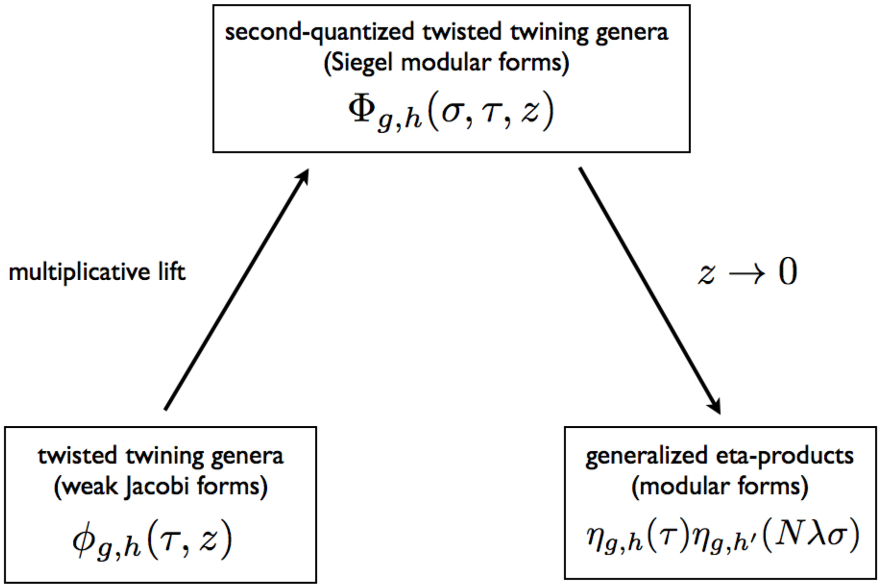
$$\lim_{z\to 0}\frac{\Phi_{g,h}(\sigma,\tau,z)}{(2\pi i z)^2}=\eta_{g,h}(\tau)\eta_{g,h'}(N\lambda\sigma), \tag{1.9}$$

which generalizes (1.3). This shows that the limit $z\to 0$ of $\Phi_{g,h}(\sigma,\tau,z)$ reproduces all of Mason's generalized eta-products $\eta_{g,h}$ [33, 32], thus providing the desired link between the two moonshines. See figure 1.2 for a pictorial overview of the relation between the various modular objects.

When (g,h) lies in the conjugacy classes $(2A,2A),(3A,3A)$ and $(4B,4B)$ we can identify $\Phi_{g,h}$ with known Siegel modular forms:

$$\begin{aligned}(2A,2A)\ &:\ \Phi_{g,h}=(\Delta_2)^2 &&=\Phi^{(3)},\\ (3A,3A)\ &:\ \Phi_{g,h}=(\Delta_1)^2 &&=\Phi^{(4)},\\ (4B,4B)\ &:\ \Phi_{g,h}=(\Delta_{1/2})^2 &&=\Phi^{(5)},\end{aligned} \tag{1.10}$$

where the first equality identifies them with the squares of the weight k Siegel modular forms Δ_k obtained by Gritsenko and Nikulin [51], and the second equality with the umbral Siegel modular forms $\Phi^{(\ell)}$ of lambency $\ell = 3, 4, 5$ [30]. Thus we obtain a surprising connection between generalized Mathieu moonshine and umbral moonshine, which clearly deserves further investigation.[†]



second-quantized twisted twining genera

Figure 1: Pictorial description of the relation between generalized Mathieu moonshine, involving the twisted twining genera $\phi_{g,h}$, and Mason's generalized eta-products $\eta_{g,h}$. Starting from $\phi_{g,h}$ one constructs a second-quantized twisted twining genus $\Psi_{g,h}$, whose reciprocal becomes a Siegel modular form $\Phi_{g,h}$ after multiplying by a factor $A_{g,h}$. This is the content of the multiplicative (automorphic) lift indicated in the leftmost arrow. At the level of the Siegel modular form $\Phi_{g,h}$ one then takes the limit $z \to 0$ which produces the generalized eta-products $\eta_{g,h}(\tau)\eta_{g,h'}(N\lambda\sigma)$. Here, h' is possibly in a different class from h, as a consequence of the 'relabeling phenomenon' described in [17]. See section 4.2 for more details.

Finally, we would like to comment further on the possible physical interpretation of the functions $\Phi_{g,h}$. For $\Phi_{e,e} = \Phi_{10}$, it is of course well-known that the reciprocal $1/\Phi_{10}$ is the generating function of 1/4-BPS dyons in heterotic string theory on T^6 [52], and in this case the decomposition (1.3) becomes $1/\Phi_{10} \sim \eta(\tau)^{-24}\eta(\rho)^{-24}$, where each factor on the right hand side is identified with the partition function of 1/2 BPS-states. More generally, $1/\Phi_{e,h}$ should correspond to the partition function of "twisted dyons", and the limit (1.3) reflects the wall-crossing phenomenon when a 1/4 BPS-state splits into two 1/2 BPS-states. Similarly we expect that in general $1/\Phi_{g,h}$ should be the generating function of certain "twisted dyons" in CHL orbifolds $T^6/\mathbb{Z}_N$ of heterotic string theory [24, 25, 26, 27]. In particular, this should be true whenever g, h can be interpreted as a pair of commuting symmetries of some K3 surface and the orbifold by g is consistent. Given the results of [8], the first condition amounts to the group $\langle g, h\rangle$ having at least four orbits in the standard 24-dimensional permutation representation of M_{24}, while the second condition simply requires g to belong to some M_{23} subgroup of M_{24}. From the tables in appendix F, it is easy to check that the first condition is satisfied by all 34 groups except the groups numbered 22, 30, 31, 32. As for the remaining groups, the second condition is satisfied by at least one generator g, except for groups 4, 5, 6, 13, 14.

[†] We thank Miranda Cheng for a discussion that pointed us in this direction.

1.3 Outline

Our paper is organized as follows. In section 2 we recall some relevant facts about holomorphic orbifolds, focussing on properties of the associated twisted twinining partition functions. We explain the important role played by the third cohomology group $H^3(G, U(1))$, where G is a finite automorphism group of the holomorphic CFT. In particular, this cohomology group controls the modular properties of the twisted twining partition functions. After discussing these properties in a general context we restrict to the relevant case of $G = M_{24}$ for which we recall the main results of [17, 18]. Section 3 introduces some aspects of symmetric products of holomorphic CFT's and the connection with Hecke operators. In section 3.2 we then introduce the key notion of twisted equivariant Hecke operators that will play a crucial role in what follows. In section 3.3 we use the twisted equivariant Hecke operators to define second-quantized twisted twining genera $\Psi_{g,h}$ and we compute their infinite product expansions. The connection with Mason's eta-products is then made in section 4 by evaluating $\Psi_{g,h}$ in the limit $z \to 0$. The modular properties of the second-quantized twisted twining genera are analyzed in section 5.2. Finally, in the concluding section 6 we summarize our results and give some ideas for future research. Various background material, technical calculations and tables have been relegated to the appendices.

2 Twisted twining partition functions

In this section we review the main properties of the twisted twining partition functions associated with the orbifold of a conformal field theory (CFT) $\mathcal{C}$ by a finite group G of symmetries [53, 54, 39]. When $\mathcal{C}$ is a bosonic CFT, these are modular functions $Z_{g,h}(\tau)$ on the upper-half plane $\mathbb{H}$, associated with each commuting pair $g, h \in G$. For superconformal field theories the analogous functions include the twisted twining genera $\phi_{g,h}(\tau, z)$, which are Jacobi forms on $\mathbb{H} \times \mathbb{C}$. Our main interest is the case when $\mathcal{C}$ is a putative $\mathcal{N} = 4$ super-vertex algebra at central charge $c = 6$ with automorphism group $G = M_{24}$, but we shall keep the discussion general whenever possible. We emphasize that the existence of such a super-vertex algebra is not established and its definition seems to be problematic. Despite these issues, the properties satisfied by the twisted-twining genera are analogous to the ones expected for a non-linear sigma model with target space K3, although no such model has a group of symmetries containing M_{24}. Finally, we will provide an abstract formulation of Mathieu moonshine [1, 2, 3, 4, 5, 12] and of its generalized version [17, 18].

2.1 Definition and basic properties

Consider a two-dimensional conformal field theory $\mathcal{C}$ and let G be its symmetry group, i.e. the group of linear automorphisms of its space of states $\mathcal{H}$ that preserves the OPE of the corresponding fields and fixes (at least) the left- and right-moving Virasoro algebra. Given such data, one can construct a new conformal field theory by considering the orbifold of $\mathcal{C}$ by (a subgroup of) G. The first step in the orbifold construction consists in introducing, for each $g \in G$, the g-twisted fields Ξ_g, generating a g-twisted space of states $\mathcal{H}_g$. The defining property of the g-twisted fields is that every field of $\mathcal{C}$ has a non-trivial monodromy g when it is moved along a (sufficiently small) closed path encircling the twisted field Ξ_g. The orbifold theory is defined by including all twisted sectors in the spectrum and then restricting to the G-invariant part. The orbifold theory is a consistent CFT provided certain conditions (in particular, the level-matching condition), assuring the locality of the OPE of twisted fields, are satisfied.

Even if the consistency conditions for the orbifold theory are not satisfied, it makes sense to consider the g-twisted sector $\mathcal{H}_g$ as a module over the Virasoro algebra (or more generally, over the G-invariant part of the chiral algebra of $\mathcal{C}$). Let us consider the case where $\mathcal{C}$ is a holomorphic CFT, so that it coincides with its chiral algebra, which is a self-dual vertex operator algebra. Then, under suitable assumptions, there exists a unique irreducible g-twisted sector $\mathcal{H}_g$ for each $g \in G$ [39]. The action of a generic element $h \in G$ on $\mathcal{C}$ induces a linear map

$$\rho_g(h) : \mathcal{H}_g \to \mathcal{H}_{h^{-1}gh} \ , \tag{2.1}$$

from the g-twisted to the $h^{-1}gh$-twisted sector. In particular, when h commutes with g, it defines an endomorphism of $\mathcal{H}_g$, so that $\mathcal{H}_g$ carries a representation ρ_g of the centralizer

$$C_G(g) := \{h \in G : gh = hg\} \ , \tag{2.2}$$

of g in G. It should be noticed that the representation ρ_g of $C_G(g)$ is in general only projective. This fact will play a crucial role in what follows.

Let us define a g-twisted h-twining partition function on the upper half-plane $\mathbb{H}_+$ by

$$Z_{g,h}(\tau) = \mathrm{Tr}_{\mathcal{H}_g}(\rho_g(h) q^{L_0 - \frac{c}{24}}) \ , \qquad q := e^{2\pi i \tau}, \quad g, h \in G, \ gh = hg \ . \tag{2.3}$$

When g and h are the identity, this reduces to the usual torus partition function for $\mathcal{C}$. On general physical grounds, one expects the twisted twining partition function $Z_{g,h}$ to be given by a path-integral on an elliptic curve $E_\tau \cong \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ with modular parameter τ, where the fields have monodromies g and h around the generators $-1, \tau$ of the first homology group $H_1(E_\tau, \mathbb{Z}) \cong \mathbb{Z} + \tau\mathbb{Z}$. Furthermore, each twisted twining partition function $Z_{g,h}$ is a holomorphic function of the modular parameter τ and is expected to be a modular function under the subgroup $\Gamma_{g,h} \subset SL(2, \mathbb{Z})$, that preserves the monodromies of the fields around the non-trivial cycles of the torus.

Analogous properties are expected for the twisted twining genera in superconformal field theories with an extended (at least $\mathcal{N} = (2, 2)$) superconformal algebra and a group G of symmetries preserving such an algebra. The twisted twining genera are defined as traces

$$\phi_{g,h}(\tau, z) = \mathrm{Tr}_{\mathcal{H}_g^{RR}}(h q^{L_0 - \frac{c}{24}} \bar{q}^{\tilde{L}_0 - \frac{\tilde{c}}{24}} (-1)^{F + \tilde{F}} y^{J_0}) \ , \qquad q := e^{2\pi i \tau}, \ y := e^{2\pi i z}, \tag{2.4}$$

over the Ramond-Ramond (RR) g-twisted sector $\mathcal{H}_g^{RR}$. Here J_0 is the zero mode of a $\mathfrak{u}(1)$ current algebra contained in the left $\mathcal{N} = 2$ superconformal algebra (normalized so that the charges are integral) and $(-1)^{F + \tilde{F}}$ is the total fermion number. This trace is computed by a path-integral with the same g- and h-twisted periodicity conditions for both bosonic and fermionic fields, with the insertion of an operator y^{J_0}. Although these conformal field theories are not chiral, the twisted twining partition functions are holomorphic with respect to both τ and z and are expected to be Jacobi forms of weight 0 and index $\frac{c}{6}$ under the same subgroup $\Gamma_{g,h} \subset SL(2, \mathbb{Z})$ as above.

2.2 Modular properties and the α-twist

We mentioned above that for a holomorphic CFT $\mathcal{C}$ with automorphism group G, the twisted sectors $\mathcal{H}_g$, carry projective representations ρ_g of the centralizer $C_G(g)$. This implies that ρ_g satisfies

$$\rho_g(h)\rho_g(h') = c_g(h,h')\rho_g(hh'), \qquad h,h' \in C_G(g) \ , \tag{2.5}$$

where $c_g(h,h')$ is a phase, or, more precisely, a 2-cocycle representing a class $[c_g]$ in $H^2(C_G(g),U(1))$. As a consequence, the twisted twining partition function $Z_{g,h}$ is not an honest class function on G, but rather satisfies

$$Z_{g,h}(\tau) = \frac{c_g(h,k)}{c_g(k,k^{-1}hk)} Z_{g,k^{-1}hk}(\tau), \qquad k \in C_G(g), \tag{2.6}$$

which puts strong constraints on $Z_{g,h}$ (see appendix B and [18]). The same formula also applies to the twisted twining elliptic genera $\phi_{g,h}$.

The role of the cohomology group $H^2(C_G(g),U(1))$ can in fact be derived from a more fundamental property of $\mathcal{C}$, namely that consistent orbifolds of a holomorphic CFT are classified by the third cohomology $H^3(G,U(1))$. Concretely, this implies there exists a $U(1)$-valued 3-cocycle $\alpha(g,h,k)$, with $(g,h,k) \in G\times G\times G$, representing a class $[\alpha]$ in $H^3(G,U(1))$, which in turn determines the class $[c_g] \in H^2(C_G(g),U(1))$ via the formula [47, 48]

$$c_g(x,y) := \frac{\alpha(g,x,y)\alpha(x,y,(xy)^{-1}g(xy))}{\alpha(x,x^{-1}gx,y)} \ , \qquad g,x,y \in G \ . \tag{2.7}$$

Thus, α characterizes the projective representations ρ_g. The 3-cocycle α is normalized, i.e. $\alpha(g,h,k) = 1$ whenever at least one of its arguments g,h,k is the identity. The cohomology group $H^3(G,U(1))$ also controls the modular properties of the twisted twining partition functions $Z_{g,h}$, in the sense that under a modular transformation $\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) \in SL(2,\mathbb{Z})$ they satisfy

$$\epsilon_{g,h}\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) Z_{g^d h^{-c}, g^{-b}h^a}\left(\frac{a\tau+b}{c\tau+d}\right) = Z_{g,h}(\tau), \tag{2.8}$$

where $\epsilon_{g,h}\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right)$ is a $U(1)$-valued multiplier system[‡] for $SL(2,\mathbb{Z})$ that can be explicitly constructed from the 3-cocycle $\alpha(g,h,k)$ (see appendix B). Furthermore, (2.6) generalizes to

$$Z_{g,h}(\tau) = \frac{c_g(h,k)}{c_g(k,k^{-1}hk)} Z_{k^{-1}gk,k^{-1}hk}(\tau), \qquad k \in G, \tag{2.9}$$

where conjugation is taken within the whole group G. In [18, 17] these properties were used to constrain and determine all of the twisted twining elliptic genera $\phi_{g,h}$ for g,h a commuting pair in M_{24}.

[‡] This was called $\chi_{g,h}$ in [18].

Given the rather complicated modular action in (2.8) it turns out to be very convenient to introduce a certain slash operator which combines the action of $SL(2,\mathbb{Z})$ on $(\tau; g, h)$ with the conjugation by G in (2.9). In addition this must incorporate the multiplier induced by the cocycle twist. To define the slash operator we must first define the following twisted modular action on commuting pairs of elements (g,h) in G:

$$(\gamma, k) : (g,h) \mapsto (kgk^{-1}, khk^{-1})\gamma^{-1} = (kg^d h^{-c} k^{-1}, kg^{-b} h^a k^{-1}) \ . \tag{2.10}$$

Here, $(\gamma, k) = \left(\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right), k \right) \in SL(2,\mathbb{Z}) \times G$.

When acting on twisted twining partition functions $Z_{g,h}$ the α-twisted equivariant slash operator is defined as follows

$$Z_{g,h}(\tau)|_\alpha(\gamma,k) := \epsilon_{g,h}(\gamma,k) Z_{(\gamma,k)\cdot(g,h)}(\gamma \cdot \tau) \ , \qquad (\gamma,k) \in SL(2,\mathbb{Z}) \times G \ , \tag{2.11}$$

where $\epsilon_{g,h}(\gamma,k) \in U(1)$ is a phase which depends on the choice of 3-cocycle α representing a class $[\alpha] \in H^3(G, U(1))$ (see appendix B.2 for more details). When $k = e$ this phase reduces to the phase $\epsilon_{g,h}(\gamma, e) = \epsilon_{g,h}(\gamma)$ in (2.8), while for $\gamma = 1$ we have that $\epsilon_{g,h}(1,k)$ is identified with the phase in (2.9).[§]

The class $[\alpha] \in H^3(G, U(1))$ is part of the defining data of a holomorphic CFT $\mathcal{C}$ with finite automorphism group G. In general the twisted twining partition functions $Z_{g,h}(\tau)$ associated with $\mathcal{C}$ are invariant under the α-twisted slash operator

$$Z_{g,h}(\tau)|_\alpha(\gamma,k) = Z_{g,h}(\tau). \tag{2.12}$$

Different choices of representative α in the class $[\alpha]$ are related to each other by rescalings of $Z_{g,h}(\tau)$ by overall (g,h)-dependent phases. More precisely, if two normalized 3-cocycles α and α' differ by a 3-coboundary $\partial\beta$, i.e.

$$\alpha(g_1,g_2,g_3) = \alpha'(g_1,g_2,g_3) \, \frac{\beta(g_1, g_2 g_3)\beta(g_2,g_3)}{\beta(g_1 g_2, g_3)\beta(g_1,g_2)} \ , \tag{2.13}$$

for some $\beta : G \times G \to U(1)$, with $\beta(e,g) = \beta(g,e) = 1$ for all $g \in G$, then the corresponding twisted twining partition functions $Z_{g,h}$ and $Z'_{g,h}$ are related by

$$Z'_{g,h}(\tau,z) = \frac{\beta(g,h)}{\beta(h,g)} Z_{g,h}(\tau,z) \ . \tag{2.14}$$

We also define the α-twisted slash operators on the twisted twining genera $\phi_{g,h}$ by the natural generalization of (2.11) to Jacobi forms of weight 0 and index 1:

$$\phi_{g,h}(\tau,z)|_\alpha(\gamma,k) := \epsilon_{g,h}(\gamma,k) e^{-\frac{2\pi i m c z^2}{c\tau+d}} \phi_{k\,g^d h^{-c}\,k^{-1},\,k\,g^{-b}h^a\,k^{-1}}(\gamma\cdot\tau, \frac{z}{c\tau+d}). \tag{2.15}$$

[§] This phase was called $\xi_{g,h}$ in [18].

2.3 (Generalized) Mathieu moonshine

The elliptic genus of K3 is defined in physics as a refined partition function

$$\phi_{K3}(\tau,z)=\mathrm{Tr}_{\mathcal{H}}(q^{L_0-\frac{c}{24}}\bar{q}^{\tilde{L}_0-\frac{\tilde{c}}{24}}(-1)^{F+\tilde{F}}y^{J_0})\ ,\qquad q:=e^{2\pi i\tau},\ y:=e^{2\pi iz},\tag{2.16}$$

of certain conformal field theories with $\mathcal{N}=(4,4)$ superconformal algebra at central charge $c=6$, namely non-linear sigma models with target space K3. The only states contributing to this partition function are the Ramond-Ramond right-moving ground states, i.e. with $\bar{L}_0-\frac{\bar{c}}{24}=0$.

In [1], Eguchi, Ooguri and Tachikawa conjectured a relationship (subsequently dubbed Mathieu moonshine) between the elliptic genus of K3 and the largest Mathieu group M_{24}. It is useful to formulate the Mathieu moonshine conjecture (now a theorem, thanks to [12]) in terms of an abstract representation $\mathcal{H}$ of the (holomorphic) $\mathcal{N}=4$ superconformal algebra at central charge $c=6$, which is also a module for the Mathieu group M_{24}. Heuristically, $\mathcal{H}$ can be interpreted as the spectrum of R-R right-moving ground states in a generic K3 model, although it is known that no such model has M_{24} as its symmetry group [8, 11]. The module $\mathcal{H}$ also admits a $\mathbb{Z}_2$-grading by a 'right-moving fermion number' $(-1)^{\bar{F}}$, which is preserved both by the $\mathcal{N}=4$ superconformal algebra and by the action of M_{24}. The precise statement of the conjecture is as follows.

Theorem (Mathieu moonshine). *There exists unitary Ramond representation $\mathcal{H}$ of the $\mathcal{N}=4$ superconformal algebra at central charge $c=6$, $\mathbb{Z}_2$-graded by the 'right-moving fermion number' $(-1)^{\bar{F}}$, that carries a non-trivial action of the Mathieu M_{24} commuting with both the $\mathcal{N}=4$ algebra and the $\mathbb{Z}_2$-grading. Furthermore, for each $g\in M_{24}$, the twining genus*

$$\phi_g(\tau,z):=\mathrm{Tr}_{\mathcal{H}}(g\,q^{L_0-\frac{c}{24}}y^{J_0^3}(-1)^{F+\bar{F}})\ ,\qquad g\in M_{24},\tag{2.17}$$

($q:=e^{2\pi i\tau}$, $y:=e^{2\pi iz}$) is a weak Jacobi form of weight 0 and index 1 (possibly with multiplier) under $\Gamma_0(N)$, where N is the order of g. In particular, ϕ_e is the elliptic genus of K3.

A list of Jacobi forms ϕ_g, $g\in M_{24}$, satisfying the expected modular properties was proposed in [2]–[5] (see table 1 in appendix F for the explicit expressions) and the existence of the corresponding module $\mathcal{H}$ was proved in [12]. The module $\mathcal{H}$ is not uniquely determined by this description, since one can always adjoin to $\mathcal{H}$ a pair of isomorphic representations of the $\mathcal{N}=4$ algebra and M_{24} with opposite right-moving fermion number, so that they do not contribute to any twisted twining genus. However, there is a 'minimal' module that contains no such pair of representations and this is uniquely determined by the twining genera ϕ_g. Remarkably, in this minimal module, the only $\mathcal{N}=4$ representations with negative $(-1)^{\bar{F}}$

are the BPS ones. It is believed that the module $\mathcal{H}$ and the Jacobi forms ϕ_g of [2]–[5] are the unique solutions of the Mathieu moonshine conjecture, although this has not been proved yet.

In the same spirit, generalized Mathieu moonshine can be expressed in terms of the existence of twisted modules $\mathcal{H}_g$ and twisted twining genera $\phi_{g,h}$.

Conjecture (Generalized Mathieu moonshine). *For each $g \in M_{24}$, there exists a $\mathbb{Z}_2$-graded unitary Ramond representation $\mathcal{H}_g$ of the $\mathcal{N} = 4$ algebra at central charge $c = 6$, that carries a projective representation $\rho_g \colon C_{M_{24}}(g) \to GL(\mathcal{H}_g)$ of the centralizer of g in M_{24}, with group law*

$$\rho_g(h)\rho_g(k) = c_g(h,k)\rho_g(hk) \ , \qquad h,k \in C_{M_{24}}(g) \ , \tag{2.18}$$

where $c_g(h,k)$ is defined by (2.7) in terms of a normalized 3-cocyle α representing a primitive class in $H^3(M_{24}, U(1)) \cong \mathbb{Z}_{12}$. The operators $\rho_g(h)$ commute with the $\mathcal{N} = 4$ algebra and with the right-moving fermion number $(-1)^{\bar{F}}$, and we have

$$\rho_g(g) = e^{2\pi i (L_0 - \frac{c}{24})} \ . \tag{2.19}$$

Furthermore, for each pair of commuting elements $g, h \in M_{24}$, the function

$$\phi_{g,h}(\tau, z) := \mathrm{Tr}_{\mathcal{H}_g}(\rho_g(h) q^{L_0 - \frac{c}{24}} y^{J_0^3} (-1)^{F+\bar{F}}) \ , \tag{2.20}$$

satisfies the following properties:

(A) For $g = e$, where e is the identity element of M_{24}, the functions $\phi_{e,h}$ coincide with the twining genera ϕ_h constructed in [2]–[5]. In particular, $\phi_{e,e}$ is the elliptic genus of $K3$.

(B) Elliptic properties:

$$\phi_{g,h}(\tau, z + \ell\tau + \ell') = e^{-2\pi i (\ell^2 \tau + 2\ell z)} \phi_{g,h}(\tau, z) \qquad \ell, \ell' \in \mathbb{Z} \ . \tag{2.21}$$

(C) Invariance under the α-twisted slash operator (see eq.(2.15))

$$\phi_{g,h}(\tau, z)|_\alpha(\gamma, k) = \phi_{g,h}(\tau, z) \ , \qquad (\gamma, k) \in SL(2,\mathbb{Z}) \times M_{24} \ . \tag{2.22}$$

In particular, each $\phi_{g,h}$ is an even weak Jacobi form of weight 0 and index 1 under a group $\Gamma_{g,h} \subseteq PSL(2,\mathbb{Z})$, with multiplier $\chi_{g,h}$ depending on α.

These conditions were presented in [17] where all the functions $\phi_{g,h}$ were explicitly found, and strong numerical evidence was given that they decompose into projective characters of

$C_{M_{24}}(g)$ with respect to the $\mathcal{N}=4$ algebra. It was also proven in [17] that there exists a unique cohomology class $[\alpha] \in H^3(M_{24}, U(1))$ for which (A)-(C) can be satisfied and that, for each choice of a normalized representative α, the functions $\phi_{g,h}$ satisfying (A)-(C) are uniquely determined. If two normalized 3-cocycles α and α' differ by a 3-coboundary $\partial\beta$, as in (2.13), then the corresponding twisted twining genera $\phi_{g,h}$ and $\phi'_{g,h}$ are related as in (2.14)

$$\phi'_{g,h}(\tau, z) = \frac{\beta(g,h)}{\beta(h,g)}\phi_{g,h}(\tau, z) \ . \tag{2.23}$$

The explicit expressions for $\phi_{g,h}$ derived in [17] are collected in table 2 in appendix F. Although the existence of the modules $\mathcal{H}_g$ matching (2.20) is not proven yet for g different from the identity, strong evidence in this direction has been given [17]. In the rest of the paper we will assume that the conjecture holds. As in the ordinary moonshine case, one can choose minimal modules $\mathcal{H}_g$, such that the only states with negative $(-1)^{\bar{F}}$ are contained in irreducible BPS representations of $\mathcal{N}=4$. In fact, the results of [17] suggest that such states only appear in the untwisted sector $\mathcal{H}_{g=e}$.

2.4 Geometric perspective

Before we close this section we shall offer a more geometric perspective on the twisted twining genera which will be useful later on. In [55], Ganter showed that the natural home for the Norton series $f(g,h;\tau)$ [19] is the equivariant elliptic cohomology developed in [56]. We shall here give a short review of Ganter's perspective, adapted to the case of Jacobi forms on $\mathbb{H}_+ \times \mathbb{C}$, as opposed to modular forms on $\mathbb{H}_+$.

Let $\mathcal{P}$ be the set of pairs of commuting elements of M_{24}

$$\mathcal{P} := \{(g,h) \in M_{24} \mid gh = hg\} \ , \tag{2.24}$$

and $\bar{\mathcal{P}}$ the set of conjugacy classes of such pairs, i.e. the quotient of $\mathcal{P}$ with respect to $(g,h) \sim (k^{-1}gk, k^{-1}hk)$, for any $k \in M_{24}$. The set $\bar{\mathcal{P}}$ can be identified with the set of isomorphism classes of principal M_{24}-bundles over the elliptic curve $E_\tau = \mathbb{C}/(\mathbb{Z}+\tau\mathbb{Z})$. One can then consider the associated moduli space[¶] of principal M_{24}-bundles on E_τ

$$\mathcal{M} = \mathcal{P} \times (\mathbb{H}_+ \times \mathbb{C}) \,/\, M_{24} \times (SL(2,\mathbb{Z}) \ltimes \mathbb{Z}^2) \ . \tag{2.25}$$

For each pair $(g,h) \in \mathcal{P}$ there exists an $(SL(2,\mathbb{Z}) \times \mathbb{Z}^2)$-equivariant line bundle

$$\begin{tikzcd} \mathcal{L}^{\alpha}_{g,h} \arrow[d] \\ \mathcal{M} \end{tikzcd} \tag{2.26}$$

[¶] This should really be a moduli *stack* but we ignore this technical point; see [55] for a more precise description.

which is twisted by the 3-cocycle $\alpha \in H^3(M_{24}, U(1))$ [55]. Thus, for fixed (g,h) we can think of the twisted twining genus $\phi_{g,h}$ as a section of $\mathcal{L}^{\alpha}_{g,h}$. The twist by α in the bundle $\mathcal{L}^{\alpha}_{g,h}$ accounts for the α-dependent multiplier phases occurring in the modular transformations of the twisted twining genera. In the cases when α describes a trivial class in $H^3(M_{24}, U(1))$, the bundle $\mathcal{L}^{\alpha}_{g,h}$ is canonically trivialized and the associated $\phi_{g,h}$ exhibits no multiplier phase. The interpretation of the twisted twining genera as sections of $\mathcal{L}^{\alpha}_{g,h}$ will in particular play a role in section 3.3 when we discuss twisted equivariant Hecke operators.

3 Second quantization of Mathieu moonshine

In this section we construct the second quantized twisted twining genera $\Psi_{g,h}$ as the exponentiated generating function of certain twisted equivariant Hecke operators acting on $\phi_{g,h}$. The forms $\Psi_{g,h}$ have a natural interpretation in terms of generating functions of the twisted twining genera in the symmetric orbifold CFTs and we therefore begin by reviewing some relevant facts about symmetric orbifold theory. Having defined the functions $\Psi_{g,h}$ we also show that they have infinite product expansions.

3.1 Symmetric Orbifolds and Hecke Operators

Given a holomorphic CFT, or self-dual Vertex Operator Algebra (VOA), $\mathcal{C}$ with a group $G \subseteq \mathrm{Aut}(\mathcal{C})$ of automorphisms, let us consider the theory $\mathcal{C}^{\otimes L}$ obtained by taking the tensor product of L copies of $\mathcal{C}$, for some $L \geq 1$. The group of automorphisms of $\mathcal{C}^{\otimes L}$ contains the direct product of the symmetric group S_L and the group G acting diagonally on all copies of $\mathcal{C}$.[‖] The twisted twining partition function $Z^{\mathcal{C}^{\otimes L}}_{g,h}$ of the theory $\mathcal{C}^{\otimes L}$, associated to a pair of commuting elements (g,h) of the diagonal group G, is simply the L:th-power of the twisted twining partition function $Z_{g,h}$ in the original theory $\mathcal{C}$:

$$Z^{\mathcal{C}^{\otimes L}}_{g,h}(\tau) = Z_{g,h}(\tau)^L \ . \tag{3.1}$$

In other words, the path integral on the torus with boundary conditions g, h in the product theory $\mathcal{C}^{\otimes L}$ is simply the product of L copies of the path integral in the original theory with the same boundary conditions. In particular, if $Z_{g,h}$ is invariant under the α-twisted slash operator for some 3-cocycle α, then $Z^{\mathcal{C}^{\otimes L}}_{g,h}$ is invariant under the α^L-twisted slash operator.

[‖] Actually, $\mathrm{Aut}(\mathcal{C}^{\otimes L})$ contains the wreath product $S_L \wr G := S_L \ltimes (G \times \ldots \times G)$, i.e. the semidirect product of S_L and the direct product $G^L := G \times \ldots \times G$ of L copies of G, with S_L acting on G^L by the obvious permutation.

The L:th symmetric orbifold $S^L\mathcal{C}$ of $\mathcal{C}$ is defined as the orbifold of $\mathcal{C}^{\otimes L}$ by S_L, and its group of automorphisms contains the diagonal G. Therefore, one can define the twisted twining partition functions

$$Z^{(L)}_{g,h}(\tau) \equiv Z^{S^L\mathcal{C}}_{g,h}(\tau) \tag{3.2}$$

in each symmetric product. These partition functions can be computed using the usual formulae for orbifold CFTs.

The orbifold formula for $Z^{(L)}_{g,h}$ can be nicely understood in the geometric setting of section 2.4. Recall that the twisted twining partition function $Z_{g,h}(\tau)$ of a VOA $\mathcal{C}$ with $\mathrm{Aut}(\mathcal{C}) = G$ is a section of a (α-twisted) line bundle $\mathcal{L}^\alpha_{g,h}$ over the moduli space $\mathcal{M}_G$ of G-bundles over the elliptic curve $E = \mathbb{C}/\Lambda$ with $\Lambda = \mathbb{Z} + \tau\mathbb{Z}$. In this picture g and h correspond to the monodromies around the cycles -1 and τ of the elliptic curve.

As shown in [23], $Z^{(L)}_{g,h}$ can be expressed as a sum of contributions from all isomorphism classes of unramified L-fold coverings $\Upsilon : E' \to E$, namely

$$Z^{(L)}_{g,h}(\tau) \sim \sum_{\substack{\text{isomorphism classes of}\\ L\text{-fold coverings}\\ \Upsilon: E'\to E}} \Upsilon^* Z_{g,h}(\tau) \ , \tag{3.3}$$

up to a suitable normalization. Here, $\Upsilon^* Z_{g,h}$ is simply the partition function associated with the pull-back $\Upsilon^*\mathcal{L}^\alpha_{g,h} \to E'$ of the line bundle $\mathcal{L}^\alpha_{g,h}$.

Up to isomorphisms, we can consider coverings that preserve the base-point of the elliptic curve. Any *connected* unramified base-point preserving L-fold cover of $E = \mathbb{C}/\Lambda$ is given by $E' \cong \mathbb{C}/\Lambda' \to E$, $z \mapsto z$, where Λ' is a sublattice of index L in Λ. In turn, the sublattices of index L are given by $\Lambda' = M\Lambda$ for any M in the set

$$\mathrm{Mat}_L(\mathbb{Z}) := \{\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mid a,b,c,d \in \mathbb{Z}, ad - bc = L\} \tag{3.4}$$

of integral 2×2 matrices M of determinant L. In particular, when $L = 1$, the covers $\Upsilon : E' \to E$ are actually isomorphisms and are classified by $\mathrm{Mat}_1(\mathbb{Z}) \equiv SL(2,\mathbb{Z})$. Let Υ_γ denote the isomorphism associated with a specific choice of $\gamma \in SL(2,\mathbb{Z})$. The pull-back $\Upsilon^*_\gamma Z_{g,h}$ then coincides with the slash operator

$$\Upsilon^*_\gamma Z_{g,h}(\tau) = Z_{g,h}(\tau)|_\alpha(\gamma, e) \ , \qquad \gamma \in SL(2,\mathbb{Z}) \ . \tag{3.5}$$

For generic $L > 0$, the isomorphism classes of coverings are in one to one correspondence with the cosets

$$SL(2,\mathbb{Z})\backslash \mathrm{Mat}_L(\mathbb{Z}) \ , \tag{3.6}$$

and a set of coset representatives is given by

$$\begin{pmatrix} a & b \\ 0 & d \end{pmatrix} , \qquad ad = L,\ a,d > 0,\ 0 \le b < d\ . \tag{3.7}$$

Therefore, the contribution to the partition function $Z^{(L)}_{g,h}(\tau)$ from the *connected* L-fold coverings is given by

$$\mathcal{T}^{\alpha}_{L} Z_{g,h}(\tau) := \frac{1}{L} \sum_{M\in SL_2(\mathbb{Z})\backslash \mathrm{Mat}_L(\mathbb{Z})} \Upsilon^{*}_{M} Z_{g,h}(\tau) \equiv \frac{1}{L} \sum_{M\in SL_2(\mathbb{Z})\backslash \mathrm{Mat}_L(\mathbb{Z})} Z_{g,h}(\tau)|_{\alpha}(M,e)\ , \tag{3.8}$$

where $|_{\alpha}(M,e)$ is a suitable generalization of the slash operator to $\mathrm{Mat}_L(\mathbb{Z})$, that will be discussed in the following sections and in appendix C.

The full twisted twining partition function $Z^{(L)}_{g,h}$ is given by the sum over connected and disconnected L-coverings. The result is most easily expressed in terms of a generating function, which is given by the plethystic exponential of the connected contribution

$$\sum_{L=0}^{\infty} p^L Z^{(L)}_{g,h}(\tau) = \exp\Big(\sum_{L=1}^{\infty} p^L \mathcal{T}^{\alpha}_{L} Z_{g,h}(\tau)\Big)\ . \tag{3.9}$$

Explicit formulae for the (α-twisted) equivariant Hecke operators $\mathcal{T}^{\alpha}_{L}$ defined by (3.8) will be discussed in more detail in section 3.2 and appendix C.

3.2 Twisted equivariant Hecke operators

The exponential lifts $\Psi_{g,h}$ of the twisted twining genera $\phi_{g,h}$ are the analogue of the generating functions (3.9) for superconformal field theories. In particular, they can be defined in terms of some set of Hecke operators that are compatible with the properties (A)-(C) in section 2.3. This means that the Hecke action should be compatible, i.e. equivariant, with respect to the M_{24}-action on the pair (g,h), and it should incorporate the α-twist in the modular transformation. Equivariant versions of Hecke operators acting on modular forms was proposed by Ganter [55] in the context of generalized Monstrous moonshine, and we shall see that this result also applies here after some minor modifications.

3.2.1 Generalities on Hecke operators

Hecke operators are linear operators acting on modular forms. Specifically, for each $L \ge 1$ there is an operator T_L that acts on a weight k modular form $f(\tau)$ and produces another modular form $T_L f(\tau)$ of the same weight. On modular functions, i.e. weight $k=0$ modular forms, the Hecke operator is defined by

$$T_L f(\tau) := \frac{1}{L} \sum_{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \backslash \mathrm{Mat}_L(\mathbb{Z})} f\left(\frac{a\tau+b}{c\tau+d}\right) . \tag{3.10}$$

These operators have a natural generalization to Jacobi forms given by [57] (restricting to the weight 0, index m case)

$$T_L \phi(\tau, z) := \frac{1}{L} \sum_{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \backslash \mathrm{Mat}_L(\mathbb{Z})} e^{\frac{-mLcz^2}{c\tau+d}} \phi\left(\frac{a\tau+b}{c\tau+d}, \frac{Lz}{c\tau+d}\right) . \tag{3.11}$$

In fact, on Jacobi forms there exists an additional Hecke operator U_L with the simple action

$$U_L \phi(\tau, z) := \phi(\tau, Lz). \tag{3.12}$$

These operators map Jacobi forms of weight 0 and index m to Jacobi forms of weight 0 and index Lm and $L^2 m$, respectively. They also form a Hecke algebra, with the relations

$$T_m \cdot T_n = T_{mn} \ , \qquad \text{for } \gcd(m,n) = 1 \ , \tag{3.13}$$

$$U_m \cdot U_n = U_{mn} \ , \tag{3.14}$$

$$T_m \cdot U_n = U_n \cdot T_m \ , \tag{3.15}$$

$$T_p \cdot T_{p^m} = T_{p^{m+1}} + \frac{1}{p} T_{p^{m-1}} \cdot U_p \ , \qquad \text{for } p \text{ prime} \ . \tag{3.16}$$

It is easy to see that a set of representatives for the quotient $SL(2,\mathbb{Z}) \backslash \mathrm{Mat}_L(\mathbb{Z})$ can always be chosen of the form (3.7). This allows us to write the action of T_L on $\phi(\tau, z)$ as follows

$$T_L \phi(\tau, z) = \frac{1}{L} \sum_{a,d>0, ad=L} \sum_{b=0}^{d-1} \phi\left(\frac{a\tau+b}{d}, az\right) . \tag{3.17}$$

3.2.2 Twisted equivariant Hecke operators: main definition

The standard Hecke-operators T_L map weak Jacobi forms of weight 0, index 1 to weak Jacobi forms of weight 0, index L. In the generalized setting the analogous statement implies that we should have equivariant Hecke operators $\mathcal{T}_L$ that map sections of $\mathcal{L}^{\alpha}_{g,h}$ to sections of the product bundle $(\mathcal{L}^{\alpha}_{g,h})^{\otimes L}$, where $\mathcal{L}^{\alpha}_{g,h} \to \mathcal{M}$ is the line bundle discussed in section 2.4. In fact, because of the cocycle-dependent multiplier phases arising in the modular transformations of the $\phi_{g,h}$ we need to introduce a certain α-twisted version $\mathcal{T}^{\alpha}_L$ of the equivariant Hecke operator. More explicitly, if the sections of $\mathcal{L}^{\alpha}_{g,h}$ correspond to holomorphic functions $\phi_{g,h}$ on the covering space $\mathcal{P} \times \mathbb{H}_+ \times \mathbb{C}$ of $\mathcal{M}$, with an automorphy factor determined by a 3-cocycle α, then $\mathcal{T}^{\alpha}_L \phi_{g,h}$ should correspond to holomorphic functions whose automorphy factor derives from the L:th power α^L of the 3-cocycle.

Since the detailed analysis is rather technical, we will postpone it to appendix C and just quote the explicit formula for the action of the Hecke operators on a twisted twining character $\phi_{g,h}$

$$\mathcal{T}^{\alpha}_L \phi_{g,h}(\tau, z) := \frac{1}{L} \sum_{\substack{a,d>0,\\ ad=L}} \sum_{b=0}^{d-1} \epsilon_{g,h} \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix} \right) \phi_{g^d, g^{-b}h^a} \Big(\frac{a\tau + b}{d}, az \Big) \ , \tag{3.18}$$

$$\mathcal{U}^{\alpha}_L \phi_{g,h}(\tau, z) := \epsilon_{g,h} \left(\begin{smallmatrix} L & 0 \\ 0 & L \end{smallmatrix} \right) \phi_{g^L, h^L}(\tau, Lz) \ , \tag{3.19}$$

where

$$\epsilon_{g,h} \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix} \right) := \frac{\prod_{i=1}^{a-1} c_g(h, h^i)^d}{\prod_{j=1}^{d-1} c_{g^{-b}h^a}(g, g^j) \prod_{k=1}^{b} c_g(g, g^{-k}h^a)^d} \ , \tag{3.20}$$

and $c_g(x,y)$, $g, x, y \in G$, depends on the cocycle α that determines the automorphy factor of $\phi_{g,h}$ via (2.7).

As discussed in appendix C, these Hecke operators satisfy the Hecke algebra (3.13)–(3.16). The explicit expressions for $\mathcal{T}^{\alpha}_L \phi_{g,h}$, for $L = 1, 2, 3, 4$, in the case of Mathieu moonshine are collected in appendix F.

Notice that the phases $\epsilon_{g,h} \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right)$ are trivial whenever g is the identity or when the restriction of the cocycle α to the group $\langle g, h \rangle$ is trivial. An example where non-trivial phases appear is given by $\mathcal{T}^{\alpha}_2 \phi_{g,g}$, where g is in class $2B$ of M_{24}. These phases can be understood by first considering

$$\mathcal{T}^{\alpha}_2 \phi_{e,g}(\tau, z) = \frac{1}{2} \Big(\phi_{e,e}(2\tau, 2z) + \phi_{e,g}(\frac{\tau}{2}, z) + \phi_{e,g}(\frac{\tau+1}{2}, z) \Big) \ , \tag{3.21}$$

and then imposing the relations

$$\mathcal{T}^{\alpha}_2 \phi_{g,e}(\tau, z) = e^{\frac{-4\pi i z^2}{\tau}} \mathcal{T}^{\alpha}_2 \phi_{e,g}(-\frac{1}{\tau}, \frac{z}{\tau}) \ , \qquad \mathcal{T}^{\alpha}_2 \phi_{g,g}(\tau, z) = \mathcal{T}^{\alpha}_2 \phi_{g,e}(\tau + 1, z) \ . \tag{3.22}$$

Using the modular properties of $\phi_{e,g}$, we obtain

$$\mathcal{T}^{\alpha}_2 \phi_{g,e}(\tau, z) = \frac{1}{2} \Big(\phi_{g,e}(2\tau, 2z) + \phi_{e,e}(\frac{\tau}{2}, z) - \phi_{e,g}(\frac{\tau+1}{2}, z) \Big) \ , \tag{3.23}$$

$$\mathcal{T}^{\alpha}_2 \phi_{g,g}(\tau, z) = \frac{1}{2} \Big(-\phi_{g,e}(2\tau, 2z) - \phi_{e,g}(\frac{\tau}{2}, z) + \phi_{e,e}(\frac{\tau+1}{2}, z) \Big) \ , \tag{3.24}$$

where the minus signs in the last two equations are due to the non-trivial multiplier system of the twining genus $\phi_{e,g}$.

3.2.3 Central extensions

Rather than considering the projective representation ρ_g of the centralizer $C_{M_{24}}(g)$, it is often useful to work with a linear representation of a central extension

$$1 \to U(1) \to C^{\alpha}_{M_{24}}(g) \to C_{M_{24}}(g) \to 1 \ . \tag{3.25}$$

The group $C^{\alpha}_{M_{24}}(g)$ can be constructed explicitly in terms of generators and relations. Let $q(x) := e^{2\pi i x}$, $x \in \mathbb{R}/\mathbb{Z}$, be the generator of the central $U(1)$ factor and consider one generator h_α for each $h \in C_{M_{24}}(g)$. Then, $C^{\alpha}_{M_{24}}(g)$ is generated by all such elements subject to the relations

$$h_\alpha k_\alpha = q\big(\mu_g(h,k)\big)\,(hk)_\alpha \ , \qquad q(x)h_\alpha = h_\alpha q(x) \tag{3.26}$$

for all $h, k \in C_{M_{24}}(g)$. Here, $\mu_g(h,k) \in \mathbb{R}/\mathbb{Z}$ is defined by

$$e^{2\pi i \mu_g(h,k)} = c_g(h,k) \ , \tag{3.27}$$

where $c_g(h,k)$ is the 2-cocycle determining the projective representation ρ_g as in (2.5). This definition provides also a canonical lift

$$h \mapsto h_\alpha \ , \tag{3.28}$$

from $C_{M_{24}}(g)$ to its central extension $C^{\alpha}_{M_{24}}(g)$. By construction, the g-twisted sector carries a genuine representation $\tilde{\rho}_g$ of $C^{\alpha}_{M_{24}}(g)$, with

$$\tilde{\rho}_g(q(x)) = e^{2\pi i x} \ , \qquad \tilde{\rho}_g(h_\alpha) = \rho_g(h) \ , \tag{3.29}$$

for all $h \in C_{M_{24}}(g)$, $x \in \mathbb{R}/\mathbb{Z}$. A less trivial observation is that also the g^r-twisted sectors, for all $r \in \mathbb{Z}_{\geq 0}$, carry a genuine representation $\tilde{\rho}_{g,r}$ of $C^{\alpha}_{M_{24}}(g)$, defined by[**]

$$\tilde{\rho}_{g,r}(q(x)) := e^{2\pi i r x} \ , \qquad \tilde{\rho}_{g,r}(h_\alpha) \equiv \tilde{\rho}_{g,r}(h) := \frac{\rho_{g^r}(h)}{f_{g,r}(h)} \ , \tag{3.30}$$

for all $h \in C_{M_{24}}(g) \subseteq C_{M_{24}}(g^r)$, $x \in \mathbb{R}/\mathbb{Z}$, $r \in \mathbb{Z}_{\geq 0}$, where

$$f_{g,r}(h) = \prod_{i=1}^{r-1} c_h(g, g^i) \ . \tag{3.31}$$

The fact that $\tilde{\rho}_{g,r}$ are well defined representations of $C^{\alpha}_{M_{24}}(g)$ is an immediate consequence of the identity

$$c_{g^r}(h,k) = \frac{f_{g,r}(h) f_{g,r}(k)}{f_{g,r}(hk)}\, c_g(h,k)^r \ , \qquad h, k \in C(g) \ , \tag{3.32}$$

[**] We denote by the same symbol $\tilde{\rho}_{g,r}$ also the projective representation of $C_{M_{24}}(g)$ on $\mathcal{H}_{g^r}$ with $\tilde{\rho}_{g,r}(h) := \rho_{g^r}(h)/f_{g,r}(h)$

which follows from the definition of c_g in terms of α and repeated applications of the cocycle condition for α. Notice that $f_{g,1}(h) = 1$ for all $h \in C_{M_{24}}(g)$, so that $\tilde{\rho}_g \equiv \tilde{\rho}_{g,1}$.

If α and α' are different cocycle representatives of the same cohomology class $[\alpha]$, then the central extensions are isomorphic $C^{\alpha}_{M_{24}}(g) \cong C^{\alpha'}_{M_{24}}(g)$, although the corresponding lifts h_α and $h_{\alpha'}$ are different. In particular, for special choices of the representative cocycle α, it is sufficient to consider a central extension of $C_{M_{24}}(g)$ by a finite subgroup of $U(1)$. With slight abuse of notation, we will denote also these finite central extensions by $C^{\alpha}_{M_{24}}(g)$. See appendix D.2 for more details on these special choices for α.

3.2.4 Twisted equivariant Hecke operators: alternative definition

The α-twisted equivariant Hecke operators are more easily defined in terms of the central extension $C^{\alpha}_{M_{24}}(g)$ described in section 3.2.3. Set

$$\phi_{g^r_\alpha, h_\alpha}(\tau, z) := \mathrm{Tr}_{\mathcal{H}_{g^r}}\left(\tilde{\rho}_{g,r}(h_\alpha) q^{L_0 - \frac{c}{24}} y^{J^3_0} (-1)^{F+\bar{F}}\right) . \tag{3.33}$$

so that

$$\begin{aligned}
\phi_{g^d_\alpha, g_\alpha^{-b} h^a_\alpha}(\tau, z) &= \mathrm{Tr}_{\mathcal{H}_{g^d}}\left(\tilde{\rho}_{g,d}(g)^{-b} \tilde{\rho}_{g,d}(h)^a q^{L_0 - \frac{c}{24}} y^{J^3_0} (-1)^{F+\bar{F}}\right) \\
&= \frac{\prod_{i=1}^{a-1} c_g(h, h^i)^d}{\prod_{k=1}^{b} c_g(g, g^{-k} h^a)^d} \mathrm{Tr}_{\mathcal{H}_{g^d}}\left(\tilde{\rho}_{g,d}(g^{-b} h^a) q^{L_0 - \frac{c}{24}} y^{J^3_0} (-1)^{F+\bar{F}}\right) \\
&= \frac{\prod_{i=1}^{a-1} c_g(h, h^i)^d}{\prod_{j=1}^{d-1} c_{g^{-b} h^a}(g, g^j) \prod_{k=1}^{b} c_g(g, g^{-k} h^a)^d} \mathrm{Tr}_{\mathcal{H}_{g^d}}\left(\rho_{g^d}(g^{-b} h^a) q^{L_0 - \frac{c}{24}} y^{J^3_0} (-1)^{F+\bar{F}}\right) \\
&= \epsilon_{g,h}\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right) \phi_{g^d, g^{-b} h^a}(\tau, z) .
\end{aligned} \tag{3.34}$$

Therefore, we can reinterpret the α-twisted Hecke operators $\mathcal{T}^{\alpha}_L$ acting on the twisted twining genera $\phi_{g,h}$ as (untwisted) equivariant operators acting on the twisted twining genera $\phi_{g_\alpha, h_\alpha}$

$$\mathcal{T}^{\alpha}_L \phi_{g,h}(\tau, z) = \frac{1}{L} \sum_{ad=L} \sum_{b=0}^{d-1} \phi_{g^d_\alpha, g_\alpha^{-b} h^a_\alpha}\left(\frac{a\tau + b}{d}, az\right) =: \mathcal{T}_L \phi_{g_\alpha, h_\alpha}(\tau, z) . \tag{3.35}$$

This form of the Hecke operators will turn out to be very useful for some of the calculations in sections 3.3 and 4.

3.3 Second-Quantized Twisted Twining Genera

3.3.1 Definition

For any Calabi-Yau manifold X, one can define its *second-quantized* elliptic genus Ψ_X as the exponentiated generating function of the orbifold elliptic genus $\phi_{S^L X}(\tau, z)$ of the symmetric products $S^L X$ [23]. In fact, ref. [23] gave three equivalent expressions for Ψ_X:

$$\Psi_X(\sigma, \tau, z) = \sum_{L=0}^{\infty} p^L \phi_{S^L X}(\tau, z) = \exp\Big[\sum_{L=1}^{\infty} p^L (T_L \phi_X)(\tau, z)\Big] = \prod_{\substack{n>0, m\geq 0,\\ \ell \in \mathbb{Z}}} \big(1 - p^n q^m y^\ell\big)^{-c(mn,\ell)}, \tag{3.36}$$

where we have set

$$q = e^{2\pi i \tau}, \qquad y = e^{2\pi i z}, \qquad p = e^{2\pi i \rho}, \tag{3.37}$$

and $c(mn, \ell)$ are the Fourier coefficients of the elliptic genus of X:

$$\phi_X(\tau, z) = \sum_{m\geq 0, \ell\in\mathbb{Z}} c(m, \ell) q^m y^\ell. \tag{3.38}$$

Here, T_L are standard Hecke operators defined in (3.17).

It was shown in [50] that $\Phi \equiv A_X/\Psi_X$, where A_X is a simple correction factor ("Hodge anomaly") that is determined by the Hodge numbers of X, transforms as a Siegel modular form for some congruence subgroup of $Sp(4; \mathbb{Z})$.

Taking the formula (3.36) as a starting point, we now wish to define the *second quantized twisted twining genera* as follows

$$\Psi_{g,h}(\sigma, \tau, z) := \exp\Big[\sum_{L=1}^{\infty} p^L (\mathcal{T}_L^\alpha \phi_{g,h})(\tau, z)\Big], \tag{3.39}$$

where $\mathcal{T}_L^\alpha$ is the twisted equivariant Hecke operator defined in (3.18). We will later show that after including a correction factor $A_{g,h}$ the functions $\Psi_{g,h}$ transform as Siegel modular forms for some discrete subgroup $\Gamma^{(2)}_{g,h} \subset Sp(4; \mathbb{R})$ that contains the invariance group $\Gamma_{g,h} \subset SL(2, \mathbb{Z})$ of the twisted twining genera $\phi_{g,h}$.

Notice that the definition (3.39) depends on the choice of a normalized 3-cocycle α. If α and α' differ by a 3-coboundary $\partial\beta$ as in(A.5), the corresponding twisted twining genera are related as

$$\mathcal{T}_L^{\alpha'} \phi'_{g,h}(\tau, z) = e^{2\pi i \nu_{g,h} L} \mathcal{T}_L^\alpha \phi_{g,h}(\tau, z) \ , \tag{3.40}$$

where $\nu_{g,h} \in \mathbb{R}/\mathbb{Z}$ is defined as

$$e^{2\pi i \nu_{g,h}} = \frac{\beta(g, h)}{\beta(h, g)} \ , \tag{3.41}$$

so that

$$\Psi'_{g,h}(\sigma,\tau,z) = \exp\Big(\sum_{L=1}^{\infty} p^L \mathcal{T}_L^{\alpha'} \phi'_{g,h}(\tau,z)\Big) \tag{3.42}$$

$$= \exp\Big(\sum_{L=1}^{\infty} (e^{2\pi i \nu_{g,h}} p)^L\, \mathcal{T}_L^{\alpha} \phi_{g,h}(\tau,z)\Big) = \Psi_{g,h}(\sigma+\nu_{g,h},\tau,z)\ . \tag{3.43}$$

Therefore, a different choice for the cocycle representative α simply amounts to a redefinition $\sigma \to \sigma + \nu_{g,h}$ of the variable σ.

3.3.2 Infinite product representation

We shall now derive infinite product representations for the second quantized twisted twining genera $\Psi_{g,h}$ in terms of the Fourier coefficients of $\phi_{g,h}$.

Let us consider a generic commuting pair of elements $g, h \in M_{24}$, with the cocycle α inducing a possibly non-trivial multiplier for $\phi_{g,h}$. Let $N = o(g)$ be the order of g and λ the length of the shortest cycle of g in the 24-dimensional permutation representation (see Table 1 in appendix F). Then, the lift g_α of g to the central extension $C^{\alpha}_{M_{24}}(g)$, as defined in section 3.2.3, has order $N\lambda$ (see appendix D.2). For any $h \in C_{M_{24}}(g)$ the associated twisted twining genus $\phi_{g,h}$ has a Fourier expansion of the form

$$\phi_{g,h}(\tau,z) = \sum_{n=0}^{\infty}\sum_{\ell\in\mathbb{Z}} c_{g,h}\big(\frac{n}{N\lambda},\ell\big) q^{\frac{n}{N\lambda}} y^{\ell}\ , \tag{3.44}$$

where, in particular, $c_{g,h}\big(\frac{n}{N\lambda},\ell\big) = 0$ unless $n \equiv -1 \mod \lambda$. Let $M = o(h_\alpha)$ be the order of the lift h_α of h to the central extension $C^{\alpha}_{M_{24}}(g)$.[††] The logarithm of the second quantized twisted twining genus of $\phi_{g,h}$ is

---

[††] We assume that α is chosen in such a way that the order is finite.

$$\begin{aligned}\log\Psi_{g,h}(\sigma,\tau,z) &= \sum_{L=1}^{\infty} p^L \mathcal{T}_L^{\alpha}\phi_{g,h}(\tau,z)\\ &= \sum_{a,d=1}^{\infty}\frac{1}{ad}\sum_{b=0}^{d-1}\sum_{\ell\in\mathbb{Z}}\sum_{n=0}^{\infty}\epsilon_{g,h}\left(\begin{smallmatrix} a & b\\ 0 & d\end{smallmatrix}\right) c_{g^d,g^{-b}h^a}(\frac{n}{N\lambda},\ell)e^{\frac{2\pi i b n}{N\lambda d}}q^{\frac{an}{N\lambda d}}y^{a\ell}p^{ad}\\ &= \sum_{a,d=1}^{\infty}\frac{1}{ad}\sum_{\ell\in\mathbb{Z}}\sum_{n=0}^{\infty}\sum_{b=0}^{d-1} c_{g_\alpha^d,g_\alpha^{-b}h_\alpha^a}(\frac{n}{N\lambda},\ell)e^{\frac{2\pi i b n}{N\lambda d}}q^{\frac{an}{N\lambda d}}y^{a\ell}p^{ad}\\ &= \sum_{a,d=1}^{\infty}\frac{1}{a}\sum_{t,k=0}^{M-1}\frac{e^{\frac{2\pi i t(a-k)}{M}}}{M}\sum_{\ell\in\mathbb{Z}}\sum_{n=0}^{\infty}\frac{1}{d}\sum_{b=0}^{d-1} c_{g_\alpha^d,g_\alpha^{-b}h_\alpha^k}(\frac{n}{N\lambda},\ell)e^{\frac{2\pi i b n}{N\lambda d}}q^{\frac{an}{N\lambda d}}y^{a\ell}p^{ad}\\ &= \sum_{a,d=1}^{\infty}\frac{1}{a}\sum_{t,k=0}^{M-1}\frac{e^{\frac{2\pi i t(a-k)}{M}}}{M}\sum_{\ell\in\mathbb{Z}} F_{g,h}(a,d,k,\ell)y^{a\ell}p^{ad}\ ,\end{aligned} \tag{3.45}$$

where

$$F_{g,h}(a,d,k,\ell) := \sum_{n=0}^{\infty}\frac{1}{d}\sum_{b=0}^{d-1} e^{\frac{2\pi i b n}{N\lambda d}}\epsilon_{g,h}\left(\begin{smallmatrix} k & b\\ 0 & d\end{smallmatrix}\right) c_{g^d,g^{-b}h^k}(\frac{n}{N\lambda},\ell)q^{\frac{an}{dN\lambda}}\ . \tag{3.46}$$

In appendix D.1 we show that this sum can be rewritten as follows

$$F_{g,h}(a,d,k,\ell) = \sum_{m=0}^{\infty}\frac{1}{N\lambda}\sum_{b=0}^{\lambda N-1} e^{\frac{2\pi i b m}{N\lambda}}\epsilon_{g,h}\left(\begin{smallmatrix} k & b\\ 0 & d\end{smallmatrix}\right) c_{g^d,g^{-b}h^k}(\frac{md}{N\lambda},\ell)q^{\frac{am}{N\lambda}}\ . \tag{3.47}$$

By plugging this expression into (3.45) we obtain

$$\begin{aligned}\log\Psi_{g,h}(\sigma,\tau,z) =& \sum_{d=1}^{\infty}\sum_{m=0}^{\infty}\sum_{\ell\in\mathbb{Z}}\sum_{t=0}^{M-1}\hat{c}_{g,h}(d,m,\ell,t)\sum_{a=1}^{\infty}\frac{1}{a}\Big(e^{\frac{2\pi i t}{M}}q^{\frac{m}{N\lambda}}y^{\ell}p^{d}\Big)^a\\ &= -\sum_{d=1}^{\infty}\sum_{m=0}^{\infty}\sum_{\ell\in\mathbb{Z}}\sum_{t=0}^{M-1}\hat{c}_{g,h}(d,m,\ell,t)\log\big(1-e^{\frac{2\pi i t}{M}}q^{\frac{m}{N\lambda}}y^{\ell}p^{d}\big),\end{aligned} \tag{3.48}$$

where

$$\begin{aligned}\hat{c}_{g,h}(d,m,\ell,t) :=& \sum_{k=0}^{M-1}\sum_{b=0}^{\lambda N-1}\frac{e^{-\frac{2\pi i t k}{M}}}{M}\frac{e^{\frac{2\pi i b m}{\lambda N}}}{\lambda N}\epsilon_{g,h}\left(\begin{smallmatrix} k & b\\ 0 & d\end{smallmatrix}\right) c_{g^d,g^{-b}h^k}(\frac{md}{N\lambda},\ell)\\ =& \sum_{k=0}^{M-1}\sum_{b=0}^{\lambda N-1}\frac{e^{-\frac{2\pi i t k}{M}}}{M}\frac{e^{\frac{2\pi i b m}{\lambda N}}}{\lambda N}\mathrm{Tr}_{\mathcal{H}_{g^d}(\frac{md}{N\lambda},\ell)}\big(\tilde{\rho}_{g,d}(g)^{-b}\tilde{\rho}_{g,d}(h)^k(-1)^{F+\bar{F}}\big)\ .\end{aligned} \tag{3.49}$$

Eq.(3.49) implies that $\hat{c}_{g,h}(d,m,\ell,t)$ admit an interpretation as a $\mathbb{Z}_2$-graded dimension (with the grading given by $(-1)^{F+\bar{F}}$) of the simultaneous eigenspace for $\tilde{\rho}_{g,d}(g)$ and $\tilde{\rho}_{g,d}(h)$, restricted to $\mathcal{H}_{g^d}(\frac{md}{N\lambda},\ell)$, relative to the eigenvalues $e^{\frac{2\pi i m}{\lambda N}}$ and $e^{\frac{2\pi i t}{M}}$, respectively. In particular, $\hat{c}_{g,h}(d,m,\ell,t)$ is always an integer.

Thus, for the inverse of the second quantized twisted twining genus we obtain the infinite product expression

$$\frac{1}{\Psi_{g,h}(\sigma,\tau,z)} = \exp\left(-\sum_{L=1}^{\infty} p^L \mathcal{T}_L^{\alpha}\phi_{g,h}(\tau,z)\right) = \prod_{d=1}^{\infty}\prod_{m=0}^{\infty}\prod_{\ell\in\mathbb{Z}}\prod_{t=0}^{M-1}(1-e^{\frac{2\pi i t}{M}}q^{\frac{m}{N\lambda}}y^{\ell}p^{d})^{\hat{c}_{g,h}(d,m,\ell,t)} . \tag{3.50}$$

Note that (3.49) makes sense also for $d=0$, so that the infinite product in d and m can be symmetrized to obtain

$$\Phi_{g,h}(\sigma,\tau,z) := pq^{\frac{1}{N\lambda}}y \prod_{(d,m,\ell)>0}\prod_{t=0}^{M-1}(1-e^{\frac{2\pi i t}{M}}q^{\frac{m}{N\lambda}}y^{\ell}p^{d})^{\hat{c}_{g,h}(d,m,\ell,t)}, \tag{3.51}$$

where the first product runs over

$$d,m\in\mathbb{Z}_{\geq 0} \quad \text{and} \quad \begin{cases} \ell\in\mathbb{Z},\ \ell<0, & \text{if } m=0=d\ , \\ \ell\in\mathbb{Z}, & \text{otherwise.}\end{cases} \tag{3.52}$$

The prefactor $pq^{\frac{1}{N\lambda}}y$ in (3.51) has been chosen in such a way that $\Phi_{g,h}$ satisfies suitable automorphic properties, that will be described in section 5.2.

One can rewrite $\Phi_{g,h}$ in terms of the original $\Psi_{g,h}$ as

$$\Phi_{g,h}(\sigma,\tau,z) = \frac{p\psi_{g,h}(\tau,z)}{\Psi_{g,h}(\sigma,\tau,z)}, \tag{3.53}$$

where $\psi_{g,h}$ includes the $d=0$ factors in (3.51) and takes the form

$$\psi_{g,h}(\tau,z) = q^{\frac{1}{N\lambda}}y\prod_{t=0}^{M-1}\Big(\prod_{\ell<0}(1-e^{\frac{2\pi i t}{M}}y^{\ell})^{\hat{c}_{g,h}(0,0,\ell,t)}\Big)\Big(\prod_{\ell\in\mathbb{Z}}\prod_{m=1}^{\infty}(1-e^{\frac{2\pi i t}{M}}q^{\frac{m}{N\lambda}}y^{\ell})^{\hat{c}_{g,h}(0,m,\ell,t)}\Big) . \tag{3.54}$$

The numerator in (3.53) is the analogue of the “Hodge anomaly” in [50].

Infinite products of the form (3.51) were studied in [37], where it was shown that they converge for $\left(\begin{smallmatrix}\tau & z\\ z & \sigma\end{smallmatrix}\right)$ in a suitable domain of the Siegel upper half-space of 2×2 complex symmetric matrices with positive definite imaginary part

$$\mathbb{H}_2 := \Big\{Z\in \mathrm{Mat}_2(\mathbb{C}) \mid Z=Z^t,\ \mathrm{Im}Z>0\Big\} . \tag{3.55}$$

Furthermore, these products can be analytically continued to meromorphic functions on the whole $\mathbb{H}_2$, with zeroes and (possibly) poles along the rational quadratic divisor [58] (see section 4.2). As will be discussed in section 5.2, the $\Phi_{g,h}$ are Siegel modular forms under certain discrete subgroups of $Sp(4,\mathbb{R})$.

The forms $\Phi_{g,h}$ depend on the choice of the cocycle representative α. If α and α' differ by a 3-coboundary $\partial\beta$, then the corresponding forms $\Phi_{g,h}$ and $\Phi'_{g,h}$ are related by a shift in σ and an overall phase

$$\Phi'_{g,h}(\sigma,\tau,z) = e^{-2\pi i\nu_{g,h}}\Phi_{g,h}(\sigma+\nu_{g,h},\tau,z)\ , \tag{3.56}$$

where $\nu_{g,h}$ satisfies $e^{2\pi i\nu_{g,h}} = \frac{\beta(g,h)}{\beta(h,g)}$.

3.3.3 Multiplicative versus additive lift

The construction of a Siegel modular form $\Phi(\sigma,\tau,z)$ from a (weak) Jacobi form $\phi(\tau,z)$ via an infinite product representation, as exemplified by (3.51), is generally referred to as a *multiplicative (automorphic) lift*. The Jacobi form ϕ is said to be the *multiplicative seed* of the lift (see, for instance, [58, 50, 51, 59]), and we write

$$\Phi = \mathrm{Mult}[\phi]. \tag{3.57}$$

It should be stressed that the definition of $\Phi_{g,h}$ in this paper is based on the (α-twisted) equivariant Hecke operators $\mathcal{T}_L^\alpha$ rather than the ordinary T_L, as in the standard multiplicative lifts. As a consequence, the infinite product expression (3.51) involves the Fourier coefficients of many distinct Jacobi forms $\phi_{g^d,g^{-b}h^a}$, rather than a unique ϕ as, for example, in [58].

In some cases one can also obtain the Siegel modular form using a different procedure, known as the *additive lift*[‡‡]. In this case the Siegel modular form is constructed as a certain generating function (without exponentiation) of Hecke operators acting on a different Jacobi form ψ, which is then called the *additive seed*. For $\psi(\tau,z)$ a Jacobi form of weight k we write $\tilde{\psi}(\sigma,\tau,z) = p\psi(\tau,z)$ and define the additive lift as

$$\Phi = \mathrm{Add}[\psi] := \sum_{m\geq 1} m^{2-k}(T_m^-\tilde{\psi})(\sigma,\tau,z), \tag{3.58}$$

where T_m^- is a certain Hecke operator; see, e.g. [60] for the precise definition and properties of the right hand side.

As an example, consider the case of the Igusa cusp form Φ_{10} (corresponding to $\Phi_{e,e}$). The multiplicative seed is the K3 elliptic genus $\phi_{e,e} = \phi_{0,1}$ which is the unique weak Jacobi form of weight 0 and index 1. The multiplicative lift yields an infinite product formula for Φ_{10} [61]:

$$\Phi_{10} = \mathrm{Mult}[\phi_{0,1}] = pqy \prod_{(d,m,\ell)>0} \left(1-q^m y^\ell p^d\right)^{c(d,m,\ell)} \tag{3.59}$$

[‡‡] This generalizes the *Saito-Kurokawa-Maass lift* defined in [57].

where $c(d,m,\ell)$ are the Fourier coefficients of $\phi_{0,1}$. This is indeed obtained from (3.51) by restricting to $(g,h)=(e,e)$. As explained in [51] one can also obtain this Siegel modular form via an additive lift from the seed $\phi_{10,1}$ (the unique weak Jacobi form of weight 10 and index 1):

$$\Phi_{10} = \mathrm{Add}[\phi_{10,1}]. \tag{3.60}$$

We now observe that the additive seed $\phi_{10,1}$ can be expressed as $\vartheta(\tau,z)^2\eta(\tau)^{18}$ which is precisely the symmetrization factor $\psi_{g,h}$ in (3.54) when restricting to $(g,h)=(e,e)$. This is in fact a general feature that holds whenever a Siegel modular form can be realized both as an additive lift as well as a multiplicative lift. It is a consequence of the fact that the additive seed ψ is the first Fourier-Jacobi coefficient in the expansion of Φ and it is precisely this coefficient which appears as the prefactor in the symmetrization of the infinite product. For purposes we thus expect that for all (g,h) for which an additive lift exists we should have the following equalities

$$\Phi_{g,h} = \mathrm{Mult}[\phi_{g,h}] = \mathrm{Add}[\psi_{g,h}]. \tag{3.61}$$

We stress that one can of course define an additive lift of a Jacobi form via (3.58). However it is not guaranteed that when applying this procedure to $\psi_{g,h}$ one will always reproduce the functions $\Phi_{g,h}$. Moreover, not all automorphic infinite products have associated additive lifts. In general we expect that whenever $\Phi_{g,h}$ can be represented through an additive lift, the seed will be $\psi_{g,h}$. In section 5.3 we indeed verify this for a number of examples. For $(g,h)=(e,h)$ modified versions of these additive lifts have also been considered in [62].

4 Wall-crossing and Mason's generalized moonshine for M_{24}

Already in 1990, Mason proposed an M_{24} version of Norton's generalized moonshine conjecture [32, 33]. In this section, we will establish the connection between Mason's generalized moonshine for M_{24} and the recent Mathieu moonshine involving the $K3$ elliptic genus. This involves taking the multiplicative lift $\phi_{g,h}\to\Phi_{g,h}$, defined in section 3, after which the limit $z\to 0$ reproduces the generalized eta-products $\eta_{g,h}$ constructed by Mason [33]. Thus, the exponential lift $\Phi_{g,h}$ links Mason's generalized M_{24}-moonshine to the M_{24}/K3-moonshine considered here. This connection was first suggested in [2] for the special case of the twining genera $\phi_{1,h}=\phi_h$. A pictorial overview of this relation is given in figure 1.2. We begin by reviewing Mason's construction of the generalized eta-products $\eta_{g,h}$ and explain their interpretation in terms of partition functions of twisted chiral bosons. Physically, the Siegel modular forms $\Phi_{g,h}$ have interpretations as generating functions of twisted dyons in (CHL) orbifolds of $\mathcal{N}=4$ string theory, and the eta-products emerge as a result of a wall-crossing formula, generalizing the one written down in [2] for $\Phi_{e,h}$.

4.1 Mason's generalized M_{24}-moonshine

For each commuting pair $(g,h) \in M_{24}$, Mason associates a modular function on the upper half-plane satisfying the requirements posed by Norton in [19]. The starting point of Mason was the 24-dimensional permutation representation of M_{24} in which each element can be associated to a *cycle shape*, which describes the element as a product of cycles of permutations. For instance, in this representation the identity element is represented by the cycle shape 1^{24}, corresponding to the product of 24 identity permutations, while the elements in class $2A$ are represented by $1^8 2^8$, corresponding to the product of 8 identity permutations followed by 8 consecutive order 2 permutations.

Mason's functions were all given in terms of so called *eta-products*, namely products of Dedekind eta-functions. Suppose an order M element $h \in M_{24}$ has cycle shape

$$\prod_{\ell|M} \ell^{i(\ell)} \ , \tag{4.1}$$

on the 24-dimensional representation of M_{24}, for some integers $i(\ell)$. Then one can associate an eta-product to h by

$$\eta_h(\tau) := \prod_{\ell|M} \eta(\ell\tau)^{i(\ell)}. \tag{4.2}$$

Mason found a generalization of such eta-products associated to "generalized cycle shapes" labelled by commuting pairs (g,h) in M_{24}. We shall denote these generalized moonshine functions by $\eta_{g,h}(\tau)$.[§§] Let $g,h \in M_{24}$ be a pair of commuting elements of order $o(g)=N$ and $o(h)=M$ and consider their action in the standard 24-dimensional representation V of M_{24}. Let $v_1,\dots,v_{24}$ be a basis of simultaneous eigenvectors for g and h, relative to the eigenvalues $(e^{\frac{2\pi i r_i}{N}}, e^{\frac{2\pi i t_i}{M}})$, $i=1,\dots,24$, with $1 \le r_i \le N$ and $1 \le t_i \le M$. Then, the eta-product $\eta_{g,h}$ is defined as

$$\eta_{g,h}(\tau) = q^{\frac{1}{N\lambda}} \prod_{i=1}^{24} \prod_{n=0}^{\infty} (1 - e^{\frac{2\pi i t_i}{M}} q^{\frac{r_i}{N}+n}) \ , \tag{4.3}$$

where λ is the length of the shortest cycle of g. In particular, the eta-products η_h of equation (4.2) correspond to $(g,h)=(e,h)$. The products $\eta_{g,h}$ (or rather their inverse) can be interpreted as h-twining partition functions for 24 g-twisted chiral free bosons.

[§§] In [33] these functions were denoted by $f(g,h;\tau)$.

As proven in [32], the eta products $\eta_{g,h}$ satisfy the modular transformations

$$\upsilon_{g,h}\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)(c\tau+d)^{-w}\eta_{g^d h^{-c},g^{-b}h^a}\left(\frac{a\tau+b}{c\tau+d}\right)=\eta_{g,h}(\tau)\ , \tag{4.4}$$

for some $\upsilon_{g,h}\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in U(1)$. The full list of Mason's generalized eta-products and the corresponding weights w can be found in Table 3. Furthermore, by definition, $\eta_{g,h}$ are invariant under conjugation in M_{24}

$$\eta_{kgk^{-1},khk^{-1}}(\tau)=\eta_{g,h}(\tau)\ . \tag{4.5}$$

4.2 Connecting the two moonshines via wall-crossing

The connection between the $K3/M_{24}$-moonshine for twining genera $\phi_h(\tau,z)$ and the M_{24}-moonshine associated with the functions $\eta_h(\tau)$ was pointed out in [2]. We now want to use our results above to establish this link also between the two different *generalized* moonshines for M_{24}.

As already mentioned, infinite products of the form (3.51) have been considered by Borcherds [58]. Although in general $\Phi_{g,h}$ are not expected to be Borcherds products in a strict sense [29], the same argument as in [58] shows that the infinite products (3.51) converge in some region of the Siegel upper half-space $\mathbb{H}_2$ and they can be analytically continued to meromorphic functions on the whole of $\mathbb{H}_2$. Furthermore, in the domain of absolute convergence of the infinite products (3.51), the zeroes and poles of $\Phi_{g,h}$ can only be located at rational quadratic divisors of the form:

$$H_{d,m,\ell,v}=\left\{\left(\begin{smallmatrix} \tau & z \\ z & \sigma \end{smallmatrix}\right) \mid \tfrac{m}{N\lambda}\tau+\ell z+d\sigma+\frac{v}{M}=0\right\}\ , \tag{4.6}$$

where $d,m,\ell,v\in\mathbb{Z}$ are coprime integers ($\gcd(d,m,\ell,v)=1$) that satisfy a positive discriminant condition

$$\ell^2-\frac{4md}{N\lambda}>0\ . \tag{4.7}$$

This property is an immediate consequence of the infinite product representation (3.51) of $\Phi_{g,h}$; the divisors of Borcherds products admit a similar description [37, 58, 63]. Using the fact that every point in the Siegel upper half-space can be brought into a domain of convergence using an $Sp(4;\mathbb{Z})$-transformation, and that the family of functions $\Phi_{g,h}$ is preserved under this action (see section 5), it follows that all divisor components can be brought to the form (4.6), for suitable $N\lambda, M$, by some $Sp(4;\mathbb{Z})$-transformation.[¶¶] This formula can be viewed as a generalisation of the rational quadratic divisor found in [25] in the context of twisted dyon counting in CHL-models.

[¶¶] Note that $Sp(4,\mathbb{Z})$ acts non-linearly on the variables σ,τ,z; therefore, even though the divisor (4.6) is defined by a linear equation in σ,τ,z, this is in general not true for its modular images.

The multiplicity of the zero or pole of $\Phi_{g,h}$ at the divisor $H_{d,m,\ell,v}$ is given by $\hat{c}_{g,h}(d,m,\ell,v)$. In particular, $\Phi_{g,h}$ is holomorphic if and only if $\hat{c}_{g,h}(d,m,\ell,v)$ is non-negative at every rational quadratic divisor. As will be shown in section 5, $\Phi_{g,h}$ is an automorphic form for a discrete subgroup $\Gamma^{(2)}_{g,h} \subset Sp(4,\mathbb{R})$. Therefore, one only needs to consider the distinct orbits of rational quadratic divisors under the action of $\Gamma^{(2)}_{g,h}$ to determine the full divisor of $\Phi_{g,h}$. The precise calculation of the divisor of each $\Phi_{g,h}$ requires knowledge of the modular group $\Gamma^{(2)}_{g,h}$ for each commuting pair (g,h) and will be left to future work.

A special role is played by (the modular orbit of) the divisor $H_{0,0,-1,0}$, corresponding to the locus $z=0$ in $\mathbb{H}_2$. Since $c_{e,g}(0,-1)=2$ for all $g\in M_{24}$, we have

$$\hat{c}_{g,h}(0,0,-1,0) = \frac{1}{MN\lambda}\sum_{k=0}^{M-1}\sum_{b=0}^{\lambda N-1} c_{e,g^{-b}h^k}(0,-1) = 2\ . \tag{4.8}$$

It follows that every $\Phi_{g,h}$ has a double zero at this divisor. Using the relation

$$\sum_{\ell\in\mathbb{Z}} c_{g,h}(r,\ell) = 0\ , \qquad \text{for } r>0\ , \tag{4.9}$$

together with the relations

$$\mathrm{Tr}_{\mathcal{H}_e(0,\pm1)}(g^{-b}h^k(-1)^{F+\bar{F}}) = 2\ , \tag{4.10}$$

$$\mathrm{Tr}_{\mathcal{H}_e(0,\pm\ell)}(g^{-b}h^k(-1)^{F+\bar{F}}) = 0 \qquad \text{for } \ell>1\ , \tag{4.11}$$

$$\sum_{\ell\in\mathbb{Z}}\mathrm{Tr}_{\mathcal{H}_e(0,\ell)}(g^{-b}h^k(-1)^{F+\bar{F}}) = \mathrm{Tr}_{\mathbf{24}}(g^{-b}h^k)\ , \tag{4.12}$$

we obtain

$$\begin{aligned}\lim_{z\to0}\frac{\Phi_{g,h}(\sigma,\tau,z)}{(2\pi iz)^2} &= \lim_{z\to0}\frac{y(1-y^{-1})^2}{(2\pi iz)^2}\Big(q^{\frac{1}{N\lambda}}\prod_{t=1}^{M}\prod_{m=1}^{\infty}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}})^{\sum_{\ell\in\mathbb{Z}}\hat{c}_{g,h}(0,m,\ell,t)}\Big)\\ &\qquad\times\Big(p\prod_{t=1}^{M}\prod_{d=1}^{\infty}(1-e^{\frac{2\pi it}{M}}p^d)^{\sum_{\ell\in\mathbb{Z}}\hat{c}_{g,h}(d,0,\ell,t)}\Big)\ .\end{aligned} \tag{4.13}$$

Next we use the relations (4.10)-(4.12) to find an expression for $\psi_{g,h}$ in (3.54) in terms of $\eta_{g,h}$ and known modular objects. Using the aforementioned equations we obtain

$$\begin{aligned}\psi_{g,h}(\tau,z) &= q^{\frac{1}{N\lambda}}y\prod_{t=0}^{M-1}\Big((1-e^{\frac{2\pi it}{M}}y^{-1})^{\hat{c}_{g,h}(0,0,-1,t)}\prod_{m=1}^{\infty}\prod_{\ell\in\mathbb{Z}}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}}y^{\ell})^{\hat{c}_{g,h}(0,m,\ell,t)}\Big)\\ &= q^{\frac{1}{N\lambda}}y(1-y^{-1})^2\prod_{n=1}^{\infty}\frac{(1-q^ny)^2(1-q^ny^{-1})^2}{(1-q^n)^4}\prod_{t=0}^{M-1}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}})^{\sum_{\ell\in\mathbb{Z}}\hat{c}_{g,h}(0,m,\ell,t)}.\end{aligned} \tag{4.14}$$

To proceed we note the identity

$$\begin{aligned}
&q^{\frac{1}{N\lambda}}\prod_{t=0}^{M-1}\prod_{m=1}^{\infty}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}})^{\sum_{k=0}^{M-1}\sum_{b=0}^{N\lambda-1}\frac{e^{-\frac{2\pi itk}{M}}}{M}\frac{e^{\frac{2\pi ibm}{N\lambda}}}{N\lambda}\mathrm{Tr}_{\mathbf{24}}(g^{-b}h^{k})}\\
&=q^{\frac{1}{N\lambda}}\prod_{t=0}^{M-1}\prod_{m=1}^{\infty}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}})^{\sum_{i=1}^{24}\frac{1}{M}\sum_{k=0}^{M-1}\frac{1}{N\lambda}\sum_{b=0}^{N\lambda-1}e^{-\frac{2\pi i(t-t_i)k}{M}}e^{\frac{2\pi ib(m-\lambda r_i)}{N\lambda}}}\\
&=q^{\frac{1}{N\lambda}}\prod_{i=1}^{24}\prod_{n=0}^{\infty}(1-e^{\frac{2\pi it_i}{M}}q^{n+\frac{r_i}{N}})=\eta_{g,h}(\tau)\ ,
\end{aligned}\tag{4.15}$$

where $1\le r_i\le N$ and $1\le t_i\le M$ are such that $(e^{\frac{2\pi ir_i}{N}},e^{\frac{2\pi it_i}{M}})$, $i=1,\dots,24$, are the (g,h)-eigenvalues of a basis of simultaneous eigenvectors for g and h in the 24-dimensional representation of M_{24}. Using this relation in (4.14) we obtain

$$\psi_{g,h}(\tau,z)=-\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^6}\eta_{g,h}(\tau)=\phi_{-2,1}(\tau,z)\eta_{g,h}(\tau)\ ,\tag{4.16}$$

where $\phi_{-2,1}$ is the standard weak Jacobi forms of weight -2 and index 1 for $SL(2,\mathbb{Z})$ (see appendix E).

To complete the analysis of the limit in (4.13) we note that

$$\lim_{z\to0}\frac{y(1-y^{-1})^2}{(2\pi iz)^2}\Big(q^{\frac{1}{N\lambda}}\prod_{t=1}^{M}\prod_{m=1}^{\infty}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N\lambda}})^{\sum_{\ell\in\mathbb{Z}}\hat{c}_{g,h}(m,0,\ell,t)}\Big)=\lim_{z\to0}\frac{\psi_{g,h}(\tau,z)}{(2\pi iz)^2}=\eta_{g,h}(\tau)\ .\tag{4.17}$$

For the pair $(g,h)=(e,e)$, the function $\Phi_{e,e}(\sigma,\tau,z)$ is invariant under the exchange $\sigma\leftrightarrow\tau$. From a physical viewpoint, this is a consequence of S-duality of type II superstring compactified on K3×T^2. In section 5.2, we will prove that $\Phi_{g,h}$ satisfy analogous transformations

$$\Phi_{g,h}(\sigma,\tau,z)=\Phi_{g,h'}(\frac{\tau}{N\lambda},N\lambda\sigma,z)\ ,\tag{4.18}$$

where $h'\in C_{M_{24}}(g)$ is not necessarily in the same conjugacy class as h. Using this identity, we conclude that

$$\lim_{z\to0}\frac{\Phi_{g,h}(\sigma,\tau,z)}{(2\pi iz)^2}=\eta_{g,h}(\tau)\eta_{g,h'}(N\lambda\sigma)\ .\tag{4.19}$$

We conjecture that this equation has a physical interpretation as a wall-crossing formula whenever $1/\Phi_{g,h}$ is the generating function of BPS-states in string theory. Indeed, for some pairs (g,h) we know that $\Phi_{g,h}^{-1}$ corresponds to the generating function for the h-twisted degeneracies of 1/4 BPS states in a CHL model. More precisely, these degeneracies are the Fourier coefficients of the automorphic form $\Phi_{g,h}^{-1}$ and the region where the Fourier expansion is performed depends on the moduli. These multiplicities jump as one crosses the pole at

$z = 0$; the physical interpretation is that some 1/4 BPS dyon corresponding to a bound state of 1/2 BPS configurations becomes unstable in a certain region of the moduli space and thus disappears from the spectrum. The mismatch $\eta_{g,h}(\tau)^{-1}\eta_{g,h'}(N\lambda\sigma)^{-1}$ between the Fourier coefficients at the two sides of the pole represents the degeneracy of a bound state of two 1/2 BPS states.

5 Automorphic Properties

In this final section we analyze the modular transformation properties of $\Phi_{g,h}(\sigma,\tau,z)$ with respect to discrete subgroups of $Sp(4,\mathbb{R})$. We show that they are Siegel modular forms and in some cases we are able to identify them with previously known objects. Our proof of modularity is done in two steps. The crucial first step is to determine the transformation properties of $\Phi_{g,h}(\sigma,\tau,z)$ with respect to the interchange $\sigma \leftrightarrow \tau$. We refer to this as "S-duality" since in the cases when $\Phi_{g,h}$ has an interpretation as a partition function in an $\mathcal{N} = 4$ string theory this corresponds precisely to the S-duality that exchanges electric and magnetic charges (see, e.g., [52, 64, 65, 24, 25]). It turns out that this transformation involves the subtle concept of "relabeling" of the group elements (g, h) introduced in [17]. By a careful analysis of this relabeling phenomenon we establish the S-duality symmetry in section 5.1. To complete the analysis of the automorphic properties of $\Phi_{g,h}(\sigma,\tau,z)$ we must also verify the transformation properties with respect to the remaining generators of the relevant modular subgroups of $Sp(4,\mathbb{R})$. This is rather straightforward since it essentially follows from the modularity of the seed functions $\phi_{g,h}(\tau,z)$ and $\psi_{g,h}(\tau,z)$. We present this analysis in section 5.2, and in section 5.3 we also investigate some examples in detail.

5.1 Relabeling and S-duality

In this section, we will show that the functions $\Phi_{g,h}(\sigma,\tau,z)$ defined by the infinite product (3.51) satisfy some 'S-duality' identities that exchange σ and τ. This property, together with the modular properties of the twisted twining genera $\phi_{g,h}$ proved in [17], will be sufficient to prove that all $\Phi_{g,h}$ are automorphic functions under some subgroup of $Sp(4,\mathbb{R})$ (see section 5.2).

5.1.1 Orbifolds and relabeling

In the case where g belongs to some M_{23} subgroup of M_{24}, the main step in the derivation of S-duality for $\Phi_{g,h}$ is the relabeling phenomenon [17]. This can be understood by considering the example of a holomorphic conformal field theory by a cyclic group. In this subsection, we review some of the standard properties of these orbifolds. See, for example, [53, 54, 39] for more details.

Let $\mathcal{C}$ be a holomorphic conformal field theory with automorphism group G. Given an element $g \in G$ of order N, let $\mathcal{C}'$ be the orbifold*** of $\mathcal{C}$ by $\langle g\rangle$. The spectrum $\mathcal{H}'$ of $\mathcal{C}'$ is constructed by considering the direct sum of the g^r-twisted representations $\mathcal{H}_{g^r}$ of $\mathcal{C}$, for all $r = 0, \dots, N-1$ and then restricting to the g-invariant sector, i.e.

$$\mathcal{H}' = \oplus_{r=0}^{N-1}\left(\mathcal{H}_{g^r}^{\langle g\rangle}\right) , \tag{5.1}$$

where $\mathcal{H}_{g^r}^{\langle g\rangle}$ denotes the g-invariant part of the g^r-twisted sector. The orbifold theory is a well-defined CFT, provided that one can define a consistent (in particularly, local) OPE between the g-invariant twisted fields. A necessary and sufficient consistency condition is that the cohomology class $[\alpha] \in H^3(G, U(1))$ is trivial when restricted to $H^3(\langle g\rangle, U(1))$ (level-matching). In what follows, we will assume that this condition is satisfied.

Each twisted sector carries a representation of some central extension $C_G^\alpha(g)$ of the centralizer $C_G(g)$ of g in G, that is compatible with the structure of twisted $\mathcal{C}$-module. As explained in section 3.2.3, there is an ambiguity in the definition of this representation. If the orbifold is consistent, the action of $C_G^\alpha(g)$ can be always chosen to be compatible also with the OPE of g-invariant twisted fields, so that it defines a group of automorphisms of the orbifold theory. In particular, for any $r, s \in \mathbb{Z}$, the representation of $C_G^\alpha(g)$ corresponding to the g^{r+s}-twisted sector must be contained in the tensor product of the representations corresponding to the g^r- and g^s-twisted sectors. A central extension satisfying this constraint can be chosen of the form

$$1 \to \langle Q\rangle \cong \mathbb{Z}_N \to C_G^\alpha(g) \to C_G(g) \to 1 , \tag{5.2}$$

where the central element Q (quantum symmetry) acts by $e^{\frac{2\pi i r}{N}}$ on the g^r-twisted sector.

Since the spectrum $\mathcal{H}'$ of $\mathcal{C}'$ consists of g-invariant states, the group acting faithfully on $\mathcal{H}'$ is $C_G^\alpha(g)/\langle g\rangle$. We conclude that $C_G^\alpha(g)/\langle g\rangle$ must be a subgroup of the group G' of automorphisms of the orbifold CFT $\mathcal{C}'$. For each $h \in C_G^\alpha(g)$, one can define the h-twining genera $Z'_{e,h}$ as in (2.3), such that

$$Z'_{e,h}(\tau) = \frac{1}{N}\sum_{r,s\in\mathbb{Z}/N\mathbb{Z}} Z_{g^r,g^sh}(\tau) . \tag{5.3}$$

***Here and in the following, we use the word ‘orbifold’ in the physicists’ sense, i.e. as a full-fledged two dimensional conformal field theory with modular invariant partition function.

Note that $Z'_{e,h}(\tau)$ only depends on the image of h in the projection $C^\alpha_G(g) \to C^\alpha_G(g)/\langle g\rangle \subseteq G'$.

The group G' of automorphisms of $\mathcal{C}'$ contains, in particular, an element g' corresponding to the quantum symmetry $g' \equiv Q$. It is well-known that by taking the orbifold of $\mathcal{C}'$ by the cyclic group $\langle g'\rangle$ one re-obtains the original CFT $\mathcal{C}$. More precisely, the g'^n-twisted sector $\mathcal{H}'_{g'^n}$ can be identified with the direct sum

$$\mathcal{H}'_{g'^n} = \oplus_{r=0}^{N-1} \mathcal{H}_{g^r,n} \ , \tag{5.4}$$

where $\mathcal{H}_{g^r,n}$ is the g-eigenspace with eigenvalue $e^{\frac{2\pi i n}{N}}$ in the g^r-twisted sector $\mathcal{H}_{g^r}$ of the CFT $\mathcal{C}$. Under the identification (5.4), the g'-invariant sector of the direct sum $\oplus_{n=0}^{N-1}\mathcal{H}'_{g'^n}$ corresponds indeed to the spectrum $\mathcal{H}$ of the original theory $\mathcal{C}$ and the quantum symmetry Q' corresponds to g. The identification (5.4) can be refined as

$$\mathcal{H}'_{g'^n,r} \cong \mathcal{H}_{g^r,n} \ , \tag{5.5}$$

where $\mathcal{H}'_{g'^n,r}$ is the g'-eigenspace with eigenvalue $e^{\frac{2\pi i m}{N}}$ in the twisted sector $\mathcal{H}'_{g'^n}$. Eq.(5.5) is an isomorphism between (untwisted) modules over the common subalgebra $\mathcal{C}^{\langle g\rangle} = \mathcal{C}'^{\langle g'\rangle}$ of $\mathcal{C}$ and $\mathcal{C}'$.

Each eigenspace $\mathcal{H}_{g^r,n}$ is a representation of $C^\alpha_G(g)$. Analogously, each twisted sector $\mathcal{H}'_{g'^n}$ (and, in fact, each eigenspace $\mathcal{H}'_{g'^n,r}$) carries an action of a suitable central extension

$$1 \to \langle Q'\rangle \to C^{\alpha'}_{G'}(g') \to C_{G'}(g') \to 1 \ , \tag{5.6}$$

of $C_{G'}(g')$ for some 3-cocycle α' representing a class in $H^3(G', U(1))$. In fact, there is an isomorphism $\varphi : C^\alpha_G(g) \xrightarrow{\cong} C^{\alpha'}_{G'}(g')$ such that $\varphi(Q) = g'$, $\varphi(g) = Q'$ and the identification (5.5) is equivariant with respect to the action of the corresponding groups. As a consequence, eq.(5.3) can be generalized to obtain the formulae for the twisted twining partition functions in the theory $\mathcal{C}'$

$$Z'_{g'^n,\varphi(h)}(\tau) = \frac{1}{N}\sum_{r,s\in\mathbb{Z}/N\mathbb{Z}} e^{-\frac{2\pi i n s}{N}} Z_{g^r,g^s h}(\tau) \ , \qquad h \in C^\alpha_G(g) \ . \tag{5.7}$$

A special case occurs when the two CFTs $\mathcal{C}'$ and $\mathcal{C}$ are isomorphic, so that $G' \cong G$. If, in addition, g' and g are in the same conjugacy class of G, the isomorphism φ can be chosen to be an outer automorphism of the group $C^\alpha_G(g)$ that exchanges g and Q, i.e. $\varphi(g) = Q$ and $\varphi(Q) = g$ and such that

$$\sum_{b=0}^{N-1} \frac{e^{\frac{2\pi i r b}{N}}}{N} Z_{g^m,g^{-b}\varphi(h)}(\tau) = \sum_{s=0}^{N-1} \frac{e^{\frac{2\pi i m s}{N}}}{N} Z_{g^r,g^{-s}h}(\tau) \ . \tag{5.8}$$

Since φ is outer, it might happen that $\varphi(h)$ and h belong to different conjugacy classes of $C^\alpha_G(g)$. If this is the case, we say that the class of h has been relabeled. Roughly speaking, a similar phenomenon occurs for the Mathieu moonshine. In particular, we will see that S-duality relates a function $\Phi_{g,h}$ to a function $\Phi_{g,h'}$, where h' belongs to the 'relabeled' class.

5.1.2 Relabeling for Mathieu Moonshine

The construction described in the previous section in the case of a holomorphic conformal field theory can be repeated with minor modifications for the abstract modules $\mathcal{H}_g$ underlying the generalized Mathieu Moonshine. It should be stressed, however, that since no consistent CFT with automorphism group M_{24} and spectrum $\mathcal{H}$ exists, these properties do not follow directly from the general theory of holomorphic CFTs and need to be proved independently.

Consider an element $g \in G = M_{24}$ of order N and let $\mathcal{H}_g$ be the g-twisted sector in the generalized Mathieu Moonshine conjecture. Let $\mathcal{H}'$ be the g-invariant subspace of the direct sum of all twisted sectors

$$\mathcal{H}' = \oplus_{r=0}^{N-1} \left(\mathcal{H}_{g^r}^{\langle \tilde{\rho}_{g,r}(g) \rangle} \right) , \tag{5.9}$$

where $\mathcal{H}_{g^r}^{\langle \tilde{\rho}_{g,r}(g) \rangle}$ denotes the $\tilde{\rho}_{g,r}(g)$-invariant part of the g^r-twisted sector. The level-matching condition, i.e. the requirement that the restriction of the cohomology class $[\alpha]$ is trivial in $H^3(\langle g \rangle, U(1))$, is satisfied if and only if g is contained in some M_{23} subgroup of M_{24}, so we will consider only this case. If $\mathcal{H}$ can be interpreted as the spectrum of R-R right-moving ground states in a non-linear sigma model on K3 with a symmetry g, then $\mathcal{H}'$ corresponds to the spectrum of right-moving ground states in the g-orbifold theory. The orbifold is a consistent $\mathcal{N} = (4,4)$ SCFT with central charge 6, which turns out to be again a non-linear sigma model on K3, since its elliptic genus is

$$\begin{aligned} \mathrm{Tr}_{\mathcal{H}'} \left(q^{L_0 - \frac{c}{24}} \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} y^{J_0^3} (-1)^{F+\bar{F}} \right) &= \sum_{r,s=0}^{N-1} \frac{1}{N} \mathrm{Tr}_{\mathcal{H}_{g^r}} \left(\tilde{\rho}_{g,r}(g)^s q^{L_0 - \frac{c}{24}} \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} y^{J_0^3} (-1)^{F+\bar{F}} \right) \\ &= \frac{1}{N} \sum_{r,s=1} \phi_{g^r,g^s}(\tau, z) = \phi_{e,e}(\tau, z) \ . \end{aligned} \tag{5.10}$$

Here, the twisted twining genera ϕ_{g^r,g^s} are relative to a cocycle α satisfying the conditions (D.17) and (D.21), in particular with trivial restriction to $\langle g \rangle$. As shown in appendix D.2, in this case the associated central extension $C^\alpha_{M_{24}}(g)$ is finite

$$1 \to \langle Q \rangle \cong \mathbb{Z}_N \to C^\alpha_{M_{24}}(g) \to C_{M_{24}}(g) \to 1 \ . \tag{5.11}$$

In the theory of orbifold CFTs, the conditions (D.17) and (D.21) ensure that the action of $C^\alpha_{M_{24}}(g)$ is compatible with the OPE of the twisted fields. The identity (5.10) can be verified case by case for all $g \in M_{24}$ satisfying the level-matching condition, and holds independently of the existence of a physical interpretation in terms of orbifolds of K3 sigma models.

By (5.10), the space $\mathcal{H}'$ defined by (5.9) is isomorphic to $\mathcal{H}$ as a module over the $\mathcal{N} = 4$ superconformal algebra. As a consequence, one can define a representation of $G' = M_{24}$ over $\mathcal{H}'$ satisfying the properties of Mathieu moonshine. Furthermore, $\mathcal{H}'$ also carries a representation ρ' of $C^{\alpha}_{M_{24}}(g)/\langle g_\alpha \rangle$ given by the restriction of $\oplus_{r=0}^{N-1} \tilde{\rho}_{g,r}$ to $\mathcal{H}'$. It can be proved that, as an abstract group, $C^{\alpha}_{M_{24}}(g)/\langle g_\alpha \rangle$ is isomorphic to a subgroup of M_{24} [17]. More precisely, Q is identified with an element $g' \in G' \cong M_{24}$ in the same conjugacy class as g and the image of $C^{\alpha}_{M_{24}}(g)/\langle g \rangle$ is the centralizer $C_{M_{24}}(g')$ of g'. Therefore, the 'orbifold' construction for the Mathieu moonshine modules is perfectly analogous to the case, described in the subsection 5.1.1, where a holomorphic CFT $\mathcal{C}$ and its orbifold $\mathcal{C}'$ are isomorphic.

In analogy with the subsection 5.1.1, we can introduce some g'^n-twisted sectors $\mathcal{H}'_{g'^n}$ satisfying (5.4) and (5.5), now considered as isomorphisms of $\mathcal{N} = 4$ modules. Each twisted sector $\mathcal{H}'_{g'^n}$ carries a representation of a central extension $C^{\alpha'}_{M_{24}}(g')$ defined as in eq.(5.6). It is natural to conjecture that there is an isomorphism $\varphi : C^{\alpha}_{M_{24}}(g) \xrightarrow{\cong} C^{\alpha'}_{M_{24}}(g')$ such that the identifications (5.5) are equivariant with respect to the action of the corresponding groups. Since $g \in G$ and $g' \in G'$ belong to the same conjugacy class of $G \cong G' \cong M_{24}$, they can be identified through a suitable choice of the isomorphism $G \cong G'$. With this identification, φ defines an outer automorphism of $C^{\alpha}_{M_{24}}(g)$ exchanging g and Q. Furthermore, we expect the analogue of (5.8) to hold. More precisely, we can state the following:

Conjecture 5.1. *For all $g \in M_{23} \subset M_{24}$ and all choices of cocycle α satisfying (D.17) and (D.21) and the corresponding central extension $C^{\alpha}_{M_{24}}(g)$ as in (5.11), there is an automorphism $\varphi : C^{\alpha}_{M_{24}}(g) \to C^{\alpha}_{M_{24}}(g)$ such that $\varphi(g) = Q$, $\varphi(Q) = g$, and for all $k \in C^{\alpha}_{M_{24}}(g)$, $m, r \in \mathbb{Z}$,*

$$\sum_{b=0}^{N-1} \frac{e^{\frac{2\pi i r b}{N}}}{N} \phi_{{g_\alpha}^m, {g_\alpha}^{-b} \varphi(k)}(\tau, z) = \sum_{s=0}^{N-1} \frac{e^{\frac{2\pi i m s}{N}}}{N} \phi_{g_\alpha^r, g_\alpha^{-s} k}(\tau, z) \ . \tag{5.12}$$

The existence of automorphisms that exchange g and Q is easy to check for the elements g of order higher than 4 (thus, excluding the classes 2A and 4B of M_{24}). Indeed, in all these cases the central extension of $C_{M_{24}}(g)$ has the form $C^{\alpha}_{M_{24}}(g) \cong \langle Q \rangle \times (\langle Qg \rangle.G)$. This group clearly admits an automorphism that fixes the factor $\langle Qg \rangle.G$ and exchanges Q and g. For the classes $2A$ and $4B$, the existence of such automorphisms can be verified with the aid of the software GAP (see also the ancillary files in the arXiv version of [17]).

In order to prove the conjecture, one needs to show that, for each g, one of these automorphisms φ satisfies (5.12). Heuristically, by standard CFT arguments, a conjecture of the form 5.1 and the corresponding identities (5.12) are expected to hold for any group $H \subseteq C_{M_{24}}(g)$

admitting an interpretation as a group of symmetries of a K3 sigma model. According to the analysis in [8], such an interpretation exists whenever $H \subset M_{24}$ has at least four orbits in the 24-dimensional permutation representation; this condition is satisfied by most of the non-cyclic abelian groups $\langle g, h\rangle \subset M_{24}$ (see Table 2 in appendix F).

A more rigorous and general proof can be obtained through a direct computation. To this aim, it is useful to rephrase eq.(5.12) in terms of identities among the twisted twining genera $\phi_{g,h}$ relative to the centralizer $C_{M_{24}}(g)$ rather than the genera ϕ_{g_α,h_α} relative to its central extension $C^\alpha_{M_{24}}(g)$. Recall that any element $k \in C^\alpha_{M_{24}}(g)$ can be written as $k = Q^x h_\alpha$, for some $x \in \mathbb{Z}/N\mathbb{Z}$, $h \in C_{M_{24}}(g)$. Therefore, one needs to show that, for each $h \in C_{M_{24}}(g)$, the image $\varphi(h_\alpha) = Q^{x'} h'_\alpha$ of the lift $h_\alpha \in C^\alpha_{M_{24}}(g)$ satisfies

$$e^{\frac{2\pi i m x'}{N}} \sum_{b=0}^{N-1} \frac{e^{\frac{2\pi i r b}{N}}}{N} \epsilon_{g,h'} \left(\begin{smallmatrix} 1 & b \\ 0 & m \end{smallmatrix}\right) \phi_{g^m, g^{-b}h'}(\tau, z) = \sum_{s=0}^{N-1} \frac{e^{\frac{2\pi i m s}{N}}}{N} \epsilon_{g,h} \left(\begin{smallmatrix} 1 & s \\ 0 & r \end{smallmatrix}\right) \phi_{g^r, g^{-s}h}(\tau, z) \ , \tag{5.13}$$

for all $m, r \in \mathbb{Z}$. Given the explicit knowledge of the twisted twining genera $\phi_{g,h}$, the proof of the conjecture then amounts to verifying a long series of identities between Jacobi forms.

We have verified that, for each conjugacy class of g, there is essentially only one choice for the conjugacy class h' and $x' \in \mathbb{Z}/N\mathbb{Z}$ for which all these identities can be possibly satisfied. In particular, if g is not in one of the classes $2A$ or $4B$, then the automorphism φ necessarily satisfies

$$h' = h \ , \qquad x' = 0 \ , \tag{5.14}$$

for all $h \in C_{M_{24}}(g) \setminus \langle g\rangle$. For g in one of the classes 2A or 4B, the conjugacy class of h' in $C_{M_{24}}(g)$ for each $C_{M_{24}}(g)$-conjugacy class of h is reported in Tables 4 and 5. Notice that, in general, h and h' might belong to different conjugacy classes of M_{24}; this phenomenon has been dubbed 'relabeling' in [17]. When h and h' are in different conjugacy classes of $C_{M_{24}}(g)$, we can choose the cocycle α in such a way that $x' = 0$. When h and h' are conjugated in $C_{M_{24}}(g)$, then x' can be set to 0 if and only if $\varphi(h_\alpha)$ is conjugated with h_α in the central extension $C^\alpha_{M_{24}}(g)$. This is always the case, except for g in M_{24}-class $4B$ and h in one of the classes $2\mathrm{B}_3$ or $4\mathrm{B}_1$ of $C_{M_{24}}(g)$. In both these cases, the pair g, h generates group 20 in the list of appendix F and $\varphi(h_\alpha)$ is conjugated with $Q^2 h_\alpha$, i.e. $x' = 2$.

We have proved a subset of the identities (5.13), required for the analysis in section 5.1.3. This leads to the following theorem:

Theorem 5.2. *Conjecture 5.1 holds for all g in the classes $1A$, $2A$, $3A$, $4B$ and $8A$ of M_{24}.*

The identities (5.13) can be easily verified by considering the modular properties of both sides and comparing a sufficient number of Fourier coefficients. This is a tedious but totally straightforward calculation, so we omit the details. We leave a systematic analysis of these identities and the complete proof of the conjecture to future work.

Notice that whenever a generator g of a non-cyclic abelian subgroup $\langle g, h\rangle \subset M_{24}$ is also an element of $M_{23} \subset M_{24}$, then it is necessarily in one of the classes 2A, 3A, 4B or 8A and theorem 5.2 applies (see appendix F for a list of all such groups and their generators). As will be explained in the subsection 5.1.3, the identities (5.13) are sufficient to establish the 'S-duality invariance' of the corresponding automorphic forms $\Phi_{g,h}$. The conjecture 5.1 is trivially true in the degenerate case where g is the identity, so the automorphic forms $\Phi_{e,h}$ associated with cyclic groups satisfy an analogous property [28, 29]. For the groups $\langle g, h\rangle$ that have no generator in M_{23}, the modular properties of $\Phi_{g,h}$ will be determined in a different way in section 5.1.3.

5.1.3 S-duality invariance

In this section, we will show that the functions $\Phi_{g,h}(\sigma, \tau, z)$ defined in terms of the infinite product (3.51), satisfy identities of the form

$$\Phi_{g,h}(\sigma, \tau, z) \sim \Phi_{g,h'}(\frac{\tau}{N\lambda} + x, N\lambda\sigma, z)\ , \tag{5.15}$$

for some suitable $h' \in C_{M_{24}}(g)$ and real x that depends on the cocycle α. Here, $\sim$ denotes equality up to a phase, that depends on the cocycle α. More precisely, for each abelian subgroup $\langle g, h\rangle \subset M_{24}$, we will prove identities of the form (5.15) for at least one pair of generators (g, h). Furthermore, in all such cases the cocycle α can be chosen in such a way that $x = 0$. For the remaining pairs $(g, h) \in \mathcal{P}$, the identities (5.15) can be derived through a complete analysis of the automorphic properties of $\Phi_{g,h}$, as discussed in section 5.2.

When the function $\Phi_{g,h}$ admits a physical interpretation as the generating functions for twisted multiplicities of 1/4 BPS states in a CHL model, the identity (5.15) corresponds to S-duality exchanging electric and magnetic charges in the low energy effective action.

Case 1: *g in one of the classes* 1A, 2A, 3A, 4B *or* 8A

Let g be an element of $M_{23} \subset M_{24}$ of order N in one of the classes considered in theorem 5.2. The restriction of $[\alpha]$ to $H^3(\langle g\rangle, U(1))$ is trivial, so that $\lambda = 1$ and we can choose a representative α satisfying (D.17) and (D.21). Consider an element $h \in C_{M_{24}}(g)$ and let M be the order of the lift $h_\alpha \in C^\alpha_{M_{24}}(g)$. Then eq.(5.13) implies that for any $d, m, k \in \mathbb{Z}_{\geq 0}$, there are $h' \in C_{M_{24}}(g)$ and $x' \in \mathbb{Z}/N\mathbb{Z}$ such that

$$\sum_{s=0}^{N-1} \frac{e^{\frac{2\pi i d s}{N}}}{N} \epsilon_{g,h}\left(\begin{smallmatrix} k & s \\ 0 & m \end{smallmatrix}\right) \phi_{g^m, g^{-s}h'^k}(\tau, z) = \sum_{b=0}^{N-1} \frac{e^{\frac{2\pi i m(b-kx')}{N}}}{N} \epsilon_{g,h}\left(\begin{smallmatrix} k & b \\ 0 & d \end{smallmatrix}\right) \phi_{g^d, g^{-b}h^k}(\tau, z)\ . \tag{5.16}$$

Thus,

$$\begin{aligned}
\hat{c}_{g,h}(d,m,\ell,t) &= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=0}^{N-1} \frac{e^{\frac{2\pi i b m}{N}}}{N} \epsilon_{g,h}\left(\begin{smallmatrix} k & b \\ 0 & d \end{smallmatrix}\right) c_{g^d,g^{-b}h^k}\left(\frac{md}{N},\ell\right) &(5.17)\\
&= \sum_{k=0}^{M-1} e^{\frac{2\pi i k m x'}{N}} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{s=0}^{N-1} \frac{e^{\frac{2\pi i d s}{N}}}{N} \epsilon_{g,h'}\left(\begin{smallmatrix} k & s \\ 0 & m \end{smallmatrix}\right) c_{g^m,g^{-s}h'^k}\left(\frac{md}{N},\ell\right) &(5.18)\\
&= \hat{c}_{g,h'}\left(m,d,\ell,t+mx'\frac{M}{N}\right) \ . &(5.19)
\end{aligned}$$

If h and h' are in different conjugacy classes of $C_{M_{24}}(g)$, we can choose the representative cocycle α in the class $[\alpha]$ in such a way that $x'=0$, so that

$$\begin{aligned}
\Phi_{g,h}(\sigma,\tau,z) =& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t=0}^{M-1} \left(1-e^{\frac{2\pi i t}{M}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h}(d,m,\ell,t)} &(5.20)\\
=& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t=0}^{M-1} \left(1-e^{\frac{2\pi i t}{M}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h'}(m,d,\ell,t)} &(5.21)\\
=& \Phi_{g,h'}\left(\frac{\tau}{N},N\sigma,z\right) \ . &(5.22)
\end{aligned}$$

When h and h' are in the same conjugacy class of $C_{M_{24}}(g)$, then x' cannot be eliminated in general. This corresponds to the case when $\varphi(h_\alpha)$ is conjugated with $Q^{x'}h_\alpha$ in the central extension $C^{\alpha}_{M_{24}}(g)$. In particular, since $\varphi(h_\alpha)^M=\varphi(h_\alpha^M)=e$, this implies that $Q^{x'}$ has order M, i.e. there is an integer x such that

$$x'M = xN \ . \tag{5.23}$$

Thus,

$$\begin{aligned}
\Phi_{g,h}(\sigma,\tau,z) =& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t=0}^{M-1} \left(1-e^{\frac{2\pi i t}{M}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h}(d,m,\ell,t)} &(5.24)\\
=& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t=0}^{M-1} \left(1-e^{\frac{2\pi i t}{M}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h}(m,d,\ell,t+mx)} &(5.25)\\
=& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t'=0}^{M-1} \left(1-e^{\frac{2\pi i t'}{M}} e^{-\frac{2\pi i x m}{M}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h}(m,d,\ell,t')} &(5.26)\\
=& pq^{\frac{1}{N}}y \prod_{(d,m,\ell)>0} \prod_{t'=0}^{M-1} \left(1-e^{\frac{2\pi i t'}{M}} e^{-\frac{2\pi i x' m}{N}} q^{\frac{m}{N}} y^{\ell} p^{d}\right)^{\hat{c}_{g,h}(m,d,\ell,t')} &(5.27)\\
=& e^{\frac{2\pi i x'}{N}} \Phi_{g,h}\left(\frac{\tau-x'}{N},N\sigma,z\right) \ . &(5.28)
\end{aligned}$$

In fact, $x' \neq 0$ only when g is in class 4B and h in one of the classes $2B_3$ or $4B_1$ of $C_{M_{24}}(g)$. In both cases, the pair g, h generates group 20 in the list of appendix F and $x' = 2$. For such pairs (g, h), however, since $T_L^\alpha \phi_{g,h} = 0$ for L odd, the function $\Phi_{g,h}$ satisfies the identity

$$\Phi_{g,h}(\sigma, \tau, z) = -\Phi_{g,h}(\sigma + \frac{1}{2}, \tau, z) \ . \tag{5.29}$$

Using this identity, we conclude

$$\Phi_{g,h}(\sigma, \tau, z) = \Phi_{g,h}(\frac{\tau}{N}, N\sigma, z) \ . \tag{5.30}$$

If the conjecture 5.1 holds, then an S-duality property holds for all $\Phi_{g,h}$ such that g is an element of $M_{23} \subset M_{24}$.

Case 2: *g in one of the classes $2B$, $3B$, $4C$, $6B$, $12B$*

The calculations in this case are rather technical and have therefore been relegated to appendix D.3. Below we summarize the results.

For a suitable choice of the representative 3-cocycle α, we have

$$\Phi_{g,h}(\sigma, \tau, z) = \Phi_{g,h^{-1}}(\frac{\tau}{N^2}, N^2\sigma, z) \ , \tag{5.31}$$

if h and h^{-1} are not conjugated within $C_{M_{24}}(g)$, and

$$\Phi_{g,h}(\sigma, \tau, z) = \Phi_{g,h}(\frac{\tau}{N^2}, N^2\sigma, z) \ , \tag{5.32}$$

otherwise.

5.2 Automorphic properties

Using the results of the previous sections, we can now prove that the functions $\Phi_{g,h}(\sigma, \tau, z)$, defined by the analytic continuation of the infinite product (3.51) to the Siegel upper half-space $\mathbb{H}_2$ are automorphic forms under certain subgroups of $Sp(4, \mathbb{R})$ acting by

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \cdot Z = (AZ + B)(CZ + D)^{-1} \ , \qquad \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in Sp(4, \mathbb{R}) \tag{5.33}$$

where

$$Z = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \ . \tag{5.34}$$

Recall that the function $\Phi_{g,h}$ can be written as

$$\Phi_{g,h}(\sigma, \tau, z) = p\psi_{g,h}(\tau, z) \exp[-\sum_{N=1}^{\infty} p^L (\mathcal{T}_L^\alpha \phi_{g,h})(\tau, z)] \ , \tag{5.35}$$

where the right-hand side converges on a suitable domain in $\mathbb{H}_2$.

Let us consider the action of various generators of $Sp(4,\mathbb{R})$ on $\Phi_{g,h}$.

- The Heisenberg subgroup $H(\mathbb{Z})$ of $Sp(4,\mathbb{Z})$ is defined as

  $$H(\mathbb{Z}) = \{[\zeta,\mu,\kappa] := \begin{pmatrix}1 & 0 & 0 & \mu\\ \zeta & 1 & \mu & \kappa\\ 0 & 0 & 1 & -\zeta\\ 0 & 0 & 0 & 1\end{pmatrix}, \zeta,\mu,\kappa \ \in \mathbb{Z}\}\ , \tag{5.36}$$

  and acts by

  $$[\zeta,\mu,\kappa]\cdot(\sigma,\tau,z) = (\sigma+\kappa+2\zeta z+\zeta^2\tau,\tau,z+\mu+\zeta\tau)\ . \tag{5.37}$$

  By (5.35), using the elliptic properties of the Jacobi forms $\psi_{g,h}$ and $\mathcal{T}_L^\alpha\phi_{g,h}$, we conclude easily that every $\Phi_{g,h}$ is invariant under $H(\mathbb{Z})$.

- For many commuting pairs $g,h\in M_{24}$, the genera $\mathcal{T}_L^\alpha\phi_{g,h}$ vanish unless L is an integer multiple of some $r\equiv r_{g,h}\in\mathbb{Z}$. Therefore, $\Phi_{g,h}$ is invariant up to a multiplier under $\sigma\mapsto\sigma+\frac{1}{r}$, i.e.

  $$\Phi_{g,h}([0,0,\frac{\kappa}{r}]\cdot(\sigma,\tau,z)) = e^{-\frac{2\pi i\kappa}{r}}\Phi_{g,h}(\sigma,\tau,z)\ , \tag{5.38}$$

  where $[0,0,\frac{\kappa}{r}]\cdot(\sigma,\tau,z) = (\sigma+\frac{\kappa}{r},\tau,z)$. In particular, $r_{g,h}=1$ when g,h generate a cyclic group and for groups 13, 23, 24 and 27, $r=3$ for groups 33 and 34, $r=4$ for groups 25 and 26 and $r=2$ in all the other cases. Notice that $r_{g,h}$ always divides $N\lambda$. More generally, the transformation $[0,0,\frac{\kappa}{N\lambda}]$ relates the functions $\Phi_{g,h}$ relative to two distinct choices of the cocycle α, that differ from one each other by a $N\lambda$-root of unity.

- The twisted twining genera $\mathcal{T}_L^\alpha\phi_{g,h}$ are Jacobi forms of weight 0 and index L under a group $\Gamma_{g,h}\subset SL(2,\mathbb{Z})$ (see the tables in appendix F), up to a multiplier $\chi_{g,h}^L$. As noticed above, for each group $\langle g,h\rangle$, there is an integer $r\equiv r_{g,h}$ such that $\mathcal{T}_L^\alpha\phi_{g,h}$ vanishes unless $r|L$. Therefore, only the power $\chi_{g,h}^r$ needs to be a well-defined character of $\Gamma_{g,h}$.

  On the other hand, the properties (4.4) and (4.5) imply that the eta products $\eta_{g,h}$ are modular forms of weight w and multiplier $\upsilon_{g,h}$ under the same group $\Gamma_{g,h}$ associated with $\phi_{g,h}$. Equivalently, each $\psi_{g,h}$ is a weak Jacobi form of weight $w-2$, index 1 and multiplier $\upsilon_{g,h}$ under $\Gamma_{g,h}$.

  For each $(\gamma,k)\in SL(2,\mathbb{Z})\times M_{24}$, let us choose $\mu_{g,h}(\gamma,k)\in\mathbb{R}/\mathbb{Z}$ such that

  $$e^{2\pi i r_{g,h}\mu_{g,h}(\gamma,k)} = \Big(\epsilon_{g,h}(\gamma,k)\Big)^{r_{g,h}}\ ,\qquad \gamma\in SL(2,\mathbb{Z})\ . \tag{5.39}$$

Then for any $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z})$ and $k \in M_{24}$, we have

$$\upsilon_{g,h}(\gamma)\Phi_{(\gamma,k)\cdot(g,h)}\Big(\xi(\gamma)\cdot Z\Big) = \det(c\tau+d)^{w-2}\,\Phi_{g,h}(\sigma+\mu_{g,h}(\gamma,k),\tau,z)\ , \tag{5.40}$$

where $Z = \left(\begin{smallmatrix} \tau & z \\ z & \sigma \end{smallmatrix}\right)$ and

$$\xi\begin{pmatrix} a & b \\ c & d \end{pmatrix} := \begin{pmatrix} a & 0 & b & 0 \\ 0 & 1 & 0 & 0 \\ c & 0 & d & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}\ , \tag{5.41}$$

so that

$$\xi(\gamma)\cdot\begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} = \begin{pmatrix} \frac{a\tau+b}{c\tau+d} & \frac{z}{c\sigma+d} \\ \frac{z}{c\sigma+d} & \sigma-\frac{z^2}{c\sigma+d} \end{pmatrix}\ . \tag{5.42}$$

In particular, by taking $(\gamma,k) \in M_{24}$ stabilizing (g,h), we obtain

$$\upsilon'_{g,h}(\gamma,k)\Phi_{g,h}\Big([0,0,-\mu_{g,h}(\gamma,k)]\cdot\big(\xi(\gamma)\cdot Z\big)\Big) = \det(c\tau+d)^{w-2}\,\Phi_{g,h}(\sigma,\tau,z)\ , \tag{5.43}$$

where $\gamma \in \Gamma_{g,h}$ and

$$\upsilon'_{g,h}(\gamma,k) = \upsilon_{g,h}(\gamma)e^{-2\pi i\mu_{g,h}(\gamma,k)}\ . \tag{5.44}$$

- Finally, for several pairs (g,h) of commuting elements of M_{24}, we have proved that

  $$\Phi_{g,h}(Z) = \Phi_{g,h'}(V_{N\lambda}\cdot Z)\ , \tag{5.45}$$

  for a suitable $h' \in C_{M_{24}}(g)$ and a suitable choice of the cocycle α, where

  $$V_t = \frac{1}{\sqrt{t}}\begin{pmatrix} 0 & t & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & t & 0 \end{pmatrix}\ , \tag{5.46}$$

  acts by

  $$V_t\cdot\begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} = \begin{pmatrix} t\sigma & z \\ z & \frac{\tau}{t} \end{pmatrix}\ . \tag{5.47}$$

  Notice that in each of the 55 conjugacy classes of abelian subgroups $\langle g,h\rangle \subset M_{24}$, an identity of the form (5.45) has been proved for at least one pair of generators.

As discussed in [51, 63], for any integers $N, t > 0$, the elements

$$V_t; \qquad \xi(\gamma)\ , \quad \gamma \in \Gamma_0(N); \qquad [\zeta,\mu,\kappa/t]\ , \quad \zeta,\mu,\kappa \in \mathbb{Z}\ , \tag{5.48}$$

generate the group $\Gamma_t^+(N) = \langle \Gamma_t(N), V_t\rangle \subset Sp(4,\mathbb{R})$ which is a normal double extension of the paramodular group

$$\Gamma_t(N) = \{ \begin{pmatrix} * & t* & * & * \\ * & * & * & t^{-1}* \\ N* & Nt* & * & * \\ Nt* & Nt* & t* & * \end{pmatrix} \in Sp(4,\mathbb{Q}),\ * \in \mathbb{Z}\}\ . \tag{5.49}$$

From the discussion above, it follows that every $\Phi_{g,h}$ is a modular function under some finite index subgroup $\Gamma^{(2)}_{g,h}$ of a paramodular group $\Gamma_t \equiv \Gamma_t(1)$, for some suitable t. The image of $\Phi_{g,h}$ under the action of a generic element of Γ_t is expected to be again a function $\Phi_{g',h'}$ for some (possibly different) commuting pair $g', h' \in M_{24}$, and defined with respect to a suitable choice of the cocycle α.

Under the action of $Sp(4,\mathbb{Z})$, the functions $\Phi_{g,h}(\sigma,\tau,z)$, for all commuting $g, h \in M_{24}$, are mapped into one another, up to shifts and rescalings of the arguments, i.e., schematically, $\Phi_{g,h}(\gamma\cdot(\sigma,\tau,z)) \sim \Phi_{g',h'}(\sigma/t + x, t\tau, z)$ for suitable $t \in \mathbb{Z}$, $x \in \mathbb{R}$ (we dropped the automorphy factors). In particular, $\Phi_{g,h}$ is a Siegel modular form for some congruence subgroup of $Sp(4,\mathbb{Z})$, as proved in the following theorem.

Theorem 5.3. *For each pair of commuting elements $g, h \in M_{24}$ and for a suitable choice of the cocycle α, the function $\Phi_{g,h}(Z)$ is a meromorphic Siegel modular function of weight $w-2$ and level H for a suitable H, i.e. it is a meromorphic function on the upper half space $\mathbb{H}_2$ such that*

$$\Phi_{g,h}\big((AZ+B)(CZ+D)^{-1}\big) = \det(CZ+D)^{w-2}\Phi_{g,h}(Z)\ , \tag{5.50}$$

for all $\left(\begin{smallmatrix} A & B \\ C & D\end{smallmatrix}\right) \in \Gamma^{(2)}(H) := \ker(Sp(4,\mathbb{Z}) \to Sp(4,\mathbb{Z}/H\mathbb{Z}))$. Here, w is the weight of the corresponding Mason's eta function $\eta_{g,h}$.

Proof. It is sufficient to prove the statement for those 'special pairs' (g,h) for which we proved that $\Phi_{g,h}(\sigma,\tau,z) = \Phi_{g,h'}(\tau/t, t\sigma, z)$ for a suitable choice of representative cocycle α. Here, h' is some element in $C_{M_{24}}(g)$ (possibly different from h) and $t = N\lambda$, where, as usual, N denotes the order of g and λ the length of the shortest cycle of g as a permutation of 24 objects. Every other commuting pair of M_{24} elements can be obtained by an $SL(2,\mathbb{Z})$ transformation $(g,h)\cdot\gamma$ of one such 'special pair' (g,h), so that $\Phi_{(g,h)\cdot\gamma}$ is related to $\Phi_{g,h}$ by an $Sp(4,\mathbb{Z})$ transformation $\xi(\gamma)$. Thus, if $\Phi_{g,h}$ is a modular function under $\Gamma^{(2)}(H)$, then $\Phi_{(g,h)\cdot\gamma}$ is a modular function under $\xi(\gamma)\Gamma^{(2)}(H)\xi(\gamma)^{-1} = \Gamma^{(2)}(H)$.

There is some integer n such that the functions $\mathcal{T}_L^\alpha\phi_{g,h}$, $L \in \mathbb{Z}_{>0}$, and $\psi_{g,h}$ are weak Jacobi forms of weight 0 and index L (respectively, $w-2$ and 1) with trivial multiplier under the congruence subgroup $\Gamma(n) := \ker(SL(2,\mathbb{Z}) \to SL(2,\mathbb{Z}/n\mathbb{Z}))$. We can choose n so that also $\mathcal{T}_L^{\alpha}\phi_{g,h'}$ and $\psi_{g,h'}$ are weak Jacobi forms with trivial multiplier under the same group. Note that n is necessarily a multiple of $t = N\lambda$, since this is the smallest integer for which $\phi_{g,h}(\tau + N\lambda, z) = \phi_{g,h}(\tau, z)$. Thus, both $\Phi_{g,h}(Z)$ and $\Phi_{g,h'}(Z) = \Phi_{g,h}(V_t \cdot Z)$ transform as modular forms of weight $w-2$ under $\xi(\Gamma(n))$ and $[\zeta,\mu,0]$, for all $\zeta,\mu \in \mathbb{Z}$. Equivalently, $\Phi_{g,h}$ transforms as a Siegel modular form of weight $w-2$ under the group generated by

$$\xi(\Gamma(n)), \qquad V_t\xi(\Gamma(n))V_t, \qquad [\zeta,\mu,0], \qquad V_t[\zeta,\mu,0]V_t \qquad \zeta,\mu \in \mathbb{Z}\ , \tag{5.51}$$

which is a subgroup of $Sp(4,\mathbb{Z})$, since $t|n$. We will prove that this group contains $\Gamma^{(2)}(H)$, with $H = nt$. By Theorem 12.4 and Proposition 13.2 of [66], $\Gamma^{(2)}(nt)$ is generated by $\xi(\Gamma(nt))$ together with matrices of the form $\left(\begin{smallmatrix} \mathbb{I} & ntB \\ 0 & \mathbb{I}\end{smallmatrix}\right)$, $\left(\begin{smallmatrix} \mathbb{I} & 0 \\ ntC & \mathbb{I}\end{smallmatrix}\right)$, with B, C arbitrary 2×2 integral symmetric matrices. It is easy to check that every element of the form $\left(\begin{smallmatrix} \mathbb{I} & ntB \\ 0 & \mathbb{I}\end{smallmatrix}\right) \in \Gamma^{(2)}(nt)$ is contained in the group generated by $[\zeta,\mu,0]$ and $\xi\left(\begin{smallmatrix} 1 & bn \\ 0 & 1\end{smallmatrix}\right)$, with $\zeta,\mu,b \in \mathbb{Z}$, and every element of the form $\left(\begin{smallmatrix} \mathbb{I} & 0 \\ ntC & \mathbb{I}\end{smallmatrix}\right) \in \Gamma^{(2)}(nt)$ is contained in the group generated by $\xi\left(\begin{smallmatrix} 1 & 0 \\ cn & 1\end{smallmatrix}\right)$, $V_t\xi\left(\begin{smallmatrix} 1 & 0 \\ cn & 1\end{smallmatrix}\right)V_t$ and $V_t[\zeta,0,0]\xi\left(\begin{smallmatrix} 1 & 0 \\ n & 1\end{smallmatrix}\right)[-\zeta,0,0]V_t$, for all $\zeta, c \in \mathbb{Z}$. Clearly $\xi(\Gamma(nt))$ is a subgroup of $\xi(\Gamma(n))$, and this concludes the proof. $\square$

In section 5.3, we will discuss the precise automorphic properties of some of these functions $\Phi_{g,h}$. We leave the detailed description of the groups $\Gamma^{(2)}_{g,h}$ for all pairs g,h to a future work.

5.3 Examples

Having established that the $\Phi_{g,h}$ are indeed Siegel modular forms we now wish to analyze some specific examples in detail. We denote the pairs (g,h) by the M_{24}-conjugacy class of g and the $C_{M_{24}}(g)$-conjugacy class of h. See appendix F for more details.

$\Phi_{2A,2A_{2,3,5}}$ **(Groups 1, 2, 3)**

Groups 1, 2 and 3 are $\mathbb{Z}_2 \times \mathbb{Z}_2$ groups that contain three elements in class 2A of M_{24}. The corresponding $\Phi_{g,h}$ are identical

$$\Phi_{2A,2A_2}(\sigma,\tau,z) = \Phi_{2A,2A_3}(\sigma,\tau,z) = \Phi_{2A,2A_5}(\sigma,\tau,z)\ . \tag{5.52}$$

The 3-cocycle α can be chosen to have trivial restriction to these groups. The Hecke transforms of the twisted twining genera $\mathcal{T}_L\phi_{g,h}$ vanish unless L is a multiple of $r = 2$; in this case, they are Jacobi forms under $\Gamma_{g,h} = SL(2,\mathbb{Z})$ with trivial multiplier $\chi^2_{g,h} = 1$. The eta products for these elements are given by

$$\eta_{g,h}(\tau) = \eta(\tau)^{12}\ , \tag{5.53}$$

and are modular forms of weight $w = 6$ under $SL(2,\mathbb{Z})$ with multiplier (see eq. (5.40))

$$\upsilon_{g,h}(T) = -1 \qquad \upsilon_{g,h}(S) = -1 \ . \tag{5.54}$$

Furthermore, from the results of section 5.1.3 we deduce that, since $g \in M_{23}$ (with $N = 2$ and $\lambda = 1$), $\Phi_{g,h}$ satisfies

$$\Phi_{2A,2A_2}(\sigma,\tau,z) = \Phi_{2A,2A_3}(\frac{\tau}{2}, 2\sigma, z) \ , \qquad \Phi_{2A,2A_5}(\sigma,\tau,z) = \Phi_{2A,2A_5}(\frac{\tau}{2}, 2\sigma, z) \ . \tag{5.55}$$

Thus, $\Phi_{g,h}$ is a modular form of weight $w - 2 = 4$ with a multiplier $\upsilon_{g,h}$ given above under the subgroup of $Sp(4,\mathbb{R})$ generated by the Heisenberg group $H(\mathbb{Z})$, by $SL(2,\mathbb{Z})$ and under V_2. These elements of $Sp(4,\mathbb{R})$ generate the paramodular group $\Gamma_2^+(1)$. Furthermore, $\Phi_{g,h}$ has a double zero at the rational quadratic divisor $z \to 0$ and at all modular images of this divisor. This allows to identify $\Phi_{g,h}$ as

$$\Phi_{g,h}(Z) = \Delta_2(Z)^2 \ , \tag{5.56}$$

where Δ_2 is the modular form of weight 2 under $\Gamma_2^+(1)$ defined by Gritsenko and Nikulin in [51]. Notice that in this case the function $\psi_{g,h}$ in (4.16) is given by

$$\psi_{g,h}(\tau,z) = -\vartheta_1(\tau,z)^2\eta(\tau)^6, \tag{5.57}$$

which is the additive seed for $\Delta_2(Z)$ [51]. Hence we conclude that in this case

$$\Phi_{g,h} = \mathrm{Add}[\psi_{g,h}], \tag{5.58}$$

as claimed in section 3.3.3. The Siegel modular form $(\Delta_2)^2$ also appears in the context of umbral moonshine, where it corresponds to the Siegel modular form $\Phi^{(3)}(Z)$ (see section 2.6 of [30]). In this context $\Phi^{(3)}$ arises as the multiplicative lift of the umbral Jacobi form $Z^{(3)}(\tau,z)$ of weight 0 and index 2. It is therefore interesting to ask how this relates to our construction of $\Phi_{g,h}$ as the multiplicative lift (3.51). By comparing Fourier coefficients one can verify that we have the identity (see the table in appendix F for the result of the Hecke action)

$$\mathcal{T}_2\phi_{g,h}(\tau,z) = Z^{(3)}(\tau,z). \tag{5.59}$$

However, this does not necessarily imply that the two lifts are the same, since a priori our multiplicative lift in (3.51) differ from that in [30] since we are constructing it from the seed function $\phi_{g,h}$, which is a weak Jacobi form of weight 0 and index 1, using the equivariant Hecke operator $\mathcal{T}_L$ (the twist by the 3-cocycle α is trivial in this case). Even so, by virtue of (5.58), in the case at hand it turns out that the lifts do coincide and we thus have

$$\mathrm{Mult}[\phi_{g,h}] = \Phi^{(3)}. \tag{5.60}$$

$\Phi_{2A,2A_4}$ **(Group 7)**

The function $\Phi_{2A,2A_4}$ of group 7 satisfies

$$\Phi_{2A,2A_4}(V_2 \cdot Z) = \Phi_{2A,4B_1}(Z) \ , \tag{5.61}$$

where h' in class $4B_1$ of $C_{M_{24}}(g)$ is such that $h'^2 = g$. Therefore, the right hand side is a $Sp(4,\mathbb{Z})$ transformation of $\Phi_{e,4B}$, which is a Siegel modular form under $\Gamma_1(4) = \Gamma_0^{(2)}(4)$ [28, 29].

$\Phi_{2A,2B_{1,2}}$ **(Groups 8,9)**

The functions $\Phi_{g,h}$ for groups 8 and 9 are identical

$$\Phi_{2A,2B_1}(Z) = \Phi_{2A,2B_2}(Z) \ . \tag{5.62}$$

The twisted twining genera $\mathcal{T}_L^\alpha \phi_{g,h}$ vanish unless L is a multiple of $r = 2$; in this case, they are Jacobi forms under $\Gamma_{g,h} = \Gamma_0(2)$ with trivial multiplier. The eta products are given by

$$\eta_{g,h}(\tau) = \eta(\tau)^4 \eta(2\tau)^4 \ , \tag{5.63}$$

and are modular forms of weight $w = 4$ under $\Gamma_0(2)$ with multiplier

$$\upsilon_{g,h}\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) = -1 \qquad \upsilon_{g,h}\left(\begin{smallmatrix} 1 & 0 \\ 2 & 1 \end{smallmatrix}\right) = -1 \ . \tag{5.64}$$

Therefore, $\Phi_{g,h}$ transforms as a modular form of weight $w - 2 = 2$ under $\xi(\gamma)$, $\gamma \in \Gamma_0(2)$, with multiplier $\upsilon_{g,h}(\gamma)$. Furthermore, for a suitable choice of the cocycle α, we have

$$\Phi_{2A,2B_{1,2}}(V_2 \cdot Z) = \Phi_{2A,2B_{1,2}}(Z) \ . \tag{5.65}$$

We conclude $\Phi_{g,h}$ is a modular form of weight 2 under the paramodular group $\Gamma_2(2)$. Assuming that it is holomorphic, then it can be identified as

$$\Phi_{g,h}(Z) = Q_1(Z)^2 \ , \tag{5.66}$$

where Q_1 is the modular form of weight 1 defined by Gritsenko and Clery in [63]. This conjecture is also supported by the fact that in this case $\psi_{g,h}$ is given by

$$\psi_{g,h}(\tau, z) = -\frac{\vartheta_1(\tau, z)^2}{\eta(\tau)^2} \eta(2\tau)^4, \tag{5.67}$$

which is the square of the additive seed for Q_1 (see eq. (16) in [63]).

$\Phi_{2A,4B_4}$ **(Group 12)**

The function $\Phi_{2A,4B_4}$ of group 12 satisfies

$$\Phi_{2A,4B_4}(V_2\cdot Z)=\Phi_{2A,8A_1}(Z)\ , \tag{5.68}$$

where h' in class $8A_1$ of $C_{M_{24}}(g)$ is such that $h'^4=g$. Therefore, the right hand side is a $Sp(4,\mathbb{Z})$ transformation of $\Phi_{e,8A}$, which is a Siegel modular form under $\Gamma_1(8)=\Gamma_0^{(2)}(8)$ [29].

$\Phi_{2A,4B_{2,3,5}}$ (Groups 17,18,19)

The functions $\Phi_{g,h}$ for groups 17, 18, 19 are identical

$$\Phi_{2A,4B_2}(Z)=\Phi_{2A,4B_3}(Z)=\Phi_{2A,4B_5}(Z)\ . \tag{5.69}$$

The Jacobi forms $\mathcal{T}_L^{\alpha}\phi_{g,h}$ for these groups have exactly the same modular properties as the ones for groups 8 and 9; the eta products are also the same. Therefore, $\Phi_{g,h}$ is a modular function of weight 2 under the paramodular group $\Gamma_2(2)$.

$\Phi_{4B,4B_{4,7}}$ (Groups 25,26)

The functions $\Phi_{g,h}$ for groups 25 and 26 are identical

$$\Phi_{4B,4B_4}(Z)=\Phi_{4B,4B_7}(Z)\ . \tag{5.70}$$

The 3-cocycle α can be chosen to be trivial when restricted to $\langle g,h\rangle$. The Hecke-transformed twisted twining genera $\mathcal{T}_L\phi_{g,h}$ vanish unless L is a multiple of $r=4$; in this case, they are Jacobi forms under $\Gamma_{g,h}=SL(2,\mathbb{Z})$ with trivial multiplier. The eta products are given by

$$\eta_{g,h}(\tau)=\eta(\tau)^6\ , \tag{5.71}$$

and are modular forms of weight $w=3$ under $SL(2,\mathbb{Z})$ with multiplier

$$\upsilon_{g,h}\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)=-i\qquad \upsilon_{g,h}\left(\begin{smallmatrix}1&0\\2&1\end{smallmatrix}\right)=-i\ . \tag{5.72}$$

Furthermore,

$$\Phi_{4B,4B_4}(V_4\cdot Z)=\Phi_{4B,4B_7}(Z)\ . \tag{5.73}$$

We conclude $\Phi_{g,h}$ is a modular function of weight $w-2=1$ under the paramodular group $\Gamma_4^+(1)$ and the multiplicity at the rational quadratic divisor $z\to 0$ is non-negative. It follows that

$$\Phi_{g,h}(Z)=\Delta_{1/2}(Z)^2\ , \tag{5.74}$$

where $\Delta_{1/2}$ is the modular form of weight 1/2 defined in [51]. Also in this case the additive lift matches since

$$\psi_{g,h}(\tau,z)=-\vartheta_1(\tau,z)^2 \tag{5.75}$$

is the square of the additive seed for $\Delta_{1/2}(Z)$, and hence $\mathrm{Add}[\psi_{g,h}] = (\Delta_{1/2}(Z))^2$.

The function $(\Delta_{1/2}(Z))^2$ also corresponds to the umbral Siegel modular form $\Phi^{(5)}(Z)$, which is the multiplicative lift of the umbral Jacobi form $Z^{(5)}(\tau, z)$ of weight 0 and index 4 [30]. The relation between $Z^{(5)}(\tau, z)$ and the twisted twining genus $\phi_{g,h}$ is now:

$$(\mathcal{T}_4\phi_{g,h})(\tau, z) = Z^{(4)}(\tau, z). \tag{5.76}$$

Again, it is not a priori clear that the equivariant multiplicative lift of $\phi_{g,h}$, defined by (3.51), will coincide with the ordinary multiplicative Borcherds lift of $Z^{(5)}(\tau, z)$ considered in [30]. However, in the case at hand they do:

$$\mathrm{Mult}[\phi_{g,h}] = \Phi^{(5)}. \tag{5.77}$$

$\Phi_{3A,3A_3}$ (Group 33)

Consider the function $\Phi_{3A,3A_3}$ of groups 33. The twisted twining genera $\mathcal{T}_L^{\alpha}\phi_{g,h}$ vanish unless L is a multiple of $r = 3$; in this case, they are Jacobi forms under $\Gamma_{g,h} = SL(2,\mathbb{Z})$ with trivial multiplier. The eta product is given by

$$\eta_{g,h}(\tau) = \eta(\tau)^8 \ , \tag{5.78}$$

and is a modular form of weight $w = 4$ under $SL(2,\mathbb{Z})$ with multiplier

$$\upsilon_{g,h}\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) = e^{-\frac{2\pi i}{3}} \qquad \upsilon_{g,h}\left(\begin{smallmatrix} 0 & -1 \\ 0 & 1 \end{smallmatrix}\right) = 1 \ . \tag{5.79}$$

Furthermore,

$$\Phi_{3A,3A_3}(V_3 \cdot Z) = \Phi_{3A,3A_3}(Z) \ . \tag{5.80}$$

We conclude $\Phi_{g,h}$ is a modular function of weight $w - 2 = 2$ under the paramodular group $\Gamma_3^+(1)$ and the analysis of the multiplicities at its divisors shows that it is holomorphic with a double zero at $z = 0$. It follows that

$$\Phi_{3A,3A_3}(Z) = \Delta_1(Z)^2 \ , \tag{5.81}$$

where Δ_1 is the modular form of weight 1 defined in [51]. Also here we find that

$$\psi_{g,h}(\tau, z) = -\vartheta_1(\tau, z)^2\eta(\tau)^2 \tag{5.82}$$

is the square of the additive seed for $\Delta_1(Z)$. The function $\Delta_1(Z)^2$ coincides with the umbral Siegel modular form $\Phi^{(4)}(Z)$, which is the multiplicative lift of the umbral Jacobi form

$Z^{(4)}(\tau, z)$ of weight 0 and index 3. In this case we have that, for a suitable choice of cocycle α,

$$(\mathcal{T}_3^\alpha \phi_{g,h})(\tau, z) = Z^{(3)}(\tau, z), \tag{5.83}$$

and the equivariant and multiplicative lifts coincide:

$$\text{Mult}[\phi_{g,h}] = \Phi^{(4)}. \tag{5.84}$$

$\Phi_{3A,3B_1}$ (Group 34)

Consider the function $\Phi_{3A,3B_1}$ of group 34. The twisted twining genera $\mathcal{T}_L^\alpha \phi_{g,h}$ vanish unless L is a multiple of $r = 3$; in this case, they are Jacobi forms under $\Gamma_{g,h} = \Gamma_0(3)$ with trivial multiplier. The eta product is given by

$$\eta_{g,h}(\tau) = \eta(\tau)^2 \eta(3\tau)^2 \ , \tag{5.85}$$

and is a modular form of weight $w = 2$ under $SL(2, \mathbb{Z})$ with multiplier

$$\upsilon_{g,h}\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) = e^{-\frac{2\pi i}{3}} \qquad \upsilon_{g,h}\left(\begin{smallmatrix} 1 & 0 \\ 3 & 1 \end{smallmatrix}\right) = e^{\frac{2\pi i}{3}} \ . \tag{5.86}$$

Furthermore,

$$\Phi_{3A,3B_1}(V_3 \cdot Z) = \Phi_{3A,3B_1}(Z) \ . \tag{5.87}$$

We conclude $\Phi_{g,h}$ is a modular function of weight $w - 2 = 0$ under the paramodular group $\Gamma_3^+(3)$. Since the weight vanishes, it must necessarily be meromorphic.

6 Conclusions

In this paper we have proposed a second quantized version of (generalized) Mathieu moonshine, involving a class of Siegel modular forms $\Phi_{g,h}$ for discrete subgroups $\Gamma_{g,h}^{(2)} \subset Sp(4, \mathbb{R})$, constructed from a multiplicative lift of the twisted twining genera $\phi_{g,h}$. For certain pairs of conjugacy classes of M_{24} we were able to identify $\Phi_{g,h}$ with known Siegel modular forms. It would be interesting to extend these results and perform a more detailed investigation of all the modular groups $\Gamma_{g,h}^{(2)}$ and determine whether the remaining $\Phi_{g,h}$ coincide with known objects, or perhaps constitute new examples of Siegel modular forms. In [29], Raum proved modularity for most of the cases $\Phi_{e,h}$ and found that not all of them are of a standard Borcherds product type, but in fact correspond to certain rescaled products of Borcherds modular forms. One would like to extend this analysis to determine whether the $\Phi_{g,h}$ for $g \neq e$ also contain such rescaled Borcherds products, or some generalization thereof.

As already mentioned in the introduction, an interesting by-product of our analysis is the fact that some of the Siegel modular forms $\Phi_{g,h}$ coincide with multiplicative lifts of the umbral Jacobi forms analyzed in [30]. This might be a simple consequence of the constraints from modularity, but it might also indicate some deeper relation between umbral moonshine and generalized Mathieu moonshine which would be interesting to uncover. Could it be that some of the other products $\Phi_{g,h}$ also coincide with lifts of the more general D_n or E_n Niemeier-umbral Jacobi forms in [67]?

It is natural to wonder whether our products $\Phi_{g,h}$ have interpretations in terms of denominator formulas of some generalized Kac-Moody algebras (GKMs). It is well-known that the inverse square root of the Igusa cusp form $\Phi_{10} = \Phi_{e,e}$ constitutes one side of the denominator formula for a rank 3 GKM-algebra of hyperbolic type [61] (the other side corresponds to the additive lift in (3.60)). In the terminology of Borcherds [37], the other functions $\Phi_{e,h}$ then correspond to twisted denominator formulas for the same algebra. On the other hand, by analogy with generalized Monstrous moonshine [42, 44], we would expect that the functions $\Phi_{g,e}$ give denominator formulas for a class of rank 3 GKM-algebras. For some of the elements g of small order these algebras have indeed been constructed in [68, 69, 70, 71] in the context of CHL-models (see also [61, 60, 51] for earlier mathematical results). In this context the prefactor $pq^{\frac{1}{N\lambda}}y$ in (3.51) should have an interpretation as the exponential of the Weyl vector ρ of the algebra. If true one would expect that for fixed g, the associated twisted denominator formulas $\Phi_{g,h}$ all have the same prefactor involving the Weyl vector of the original GKM-algebra determined by the class $[g]$. In other words, the prefactor should be independent of the twining element h, and this is indeed what we find. In fact, the Weyl vectors extracted from $pq^{\frac{1}{N\lambda}}y$ reduces to the ones in [68, 69] when the length of the shortest cycle λ equals one.

As stressed in the introduction, we think that our results could have immediate applications to the understanding of dyon counting in CHL-orbifolds. In particular, most of the functions $\Phi_{g,h}$ are expected to have interpretations as partition functions of twisted dyons, and we hope to investigate this relation in more detail in a future publication.

Acknowledgments

We are especially grateful to Matthias Gaberdiel for collaboration in the initial stages of this work, and for many helpful discussions. We are also grateful to Geoff Mason for several useful discussions on M_{24} moonshine for eta-products, and for sending us a printed copy of [32]; to Miranda Cheng for a discussion that drew our attention to the connection with umbral moonshine; and to Martin Raum for helpful discussions on infinite product representations of Siegel modular forms. In addition we thank Scott Carnahan, Thomas Creutzig, Terry Gannon, Suresh Govindarajan, Jeff Harvey, Stefan Hohenegger, Gerald Höhn, Jim Lepowsky, Greg Moore, Sameer Murthy, Anne Taormina and Katrin Wendland for inspiring discussions during the course of this work. We also thank the Simons Center and the organizers of the programme "Mock Modular Forms, Moonshine, and String Theory" for providing a stimulating research environment, and all the participants for many inspiring discussions. D.P. thanks the Albert Einstein Institute in Golm, and R.V. thanks the Department of Fundamental Physics at Chalmers for hospitality while this work was carried out.

A Some group cohomology

In this appendix, we summarize some general results about group cohomology. See [72] for more details.

For a finite group G, a 2-cochain $\beta : G \times G \to U(1)$ is closed (and hence defines a cocycle) provided it satisfies

$$\beta(g_1, g_2 g_3)\beta(g_2, g_3) = \beta(g_1 g_2, g_3)\beta(g_1, g_2) \tag{A.1}$$

for $g_1, g_2, g_3 \in G$. The second cohomology $H^2(G, U(1))$ then consists of the closed 2-cochains, modulo the ambiguity

$$\beta(g_1, g_2) \to \beta(g_1, g_2)\frac{\gamma(g_1)\gamma(g_2)}{\gamma(g_1 g_2)} , \tag{A.2}$$

where $\gamma : G \to U(1)$ is an arbitrary 1-cochain, i.e. an arbitrary function $\gamma : G \to U(1)$.

A 3-cochain α,

$$\alpha : G \times G \times G \to U(1) \tag{A.3}$$

is closed provided it satisfies

$$\alpha(g_1, g_2, g_3)\,\alpha(g_1, g_2 g_3, g_4)\,\alpha(g_2, g_3, g_4) = \alpha(g_1 g_2, g_3, g_4)\,\alpha(g_1, g_2, g_3 g_4) . \tag{A.4}$$

In the cohomology group $H^3(G, U(1))$ closed 3-cochains are then identified modulo

$$\alpha(g_1, g_2, g_3) \to \alpha(g_1, g_2, g_3)\,\frac{\beta(g_1 g_2, g_3)\beta(g_1, g_2)}{\beta(g_1, g_2 g_3)\beta(g_2, g_3)} . \tag{A.5}$$

Note that the multiplying factor is trivial if β is closed, i.e. if it satisfies the 2-cocycle condition (A.1). In particular, for each cocycle α and element $x \in G$, the 3-cocycle α_x, defined by

$$\alpha_x(g, h, k) := \alpha(x^{-1}gx,\ x^{-1}hx,\ x^{-1}kx) , \tag{A.6}$$

differs from α just by a 3-coboundary [47]

$$\alpha(g_1, g_2, g_3) = \alpha_x(g_1, g_2, g_3)\, \frac{\eta_x(g_1 g_2, g_3)\eta_x(g_1, g_2)}{\eta_x(g_1, g_2 g_3)\eta_x(g_2, g_3)}, \tag{A.7}$$

where

$$\eta_z(x, y) := \frac{\alpha(x, y, z)\alpha(z, z^{-1}xz, z^{-1}yz)}{\alpha(x, z, z^{-1}yz)} \ . \tag{A.8}$$

Given a 3-cocycle α, we can define, for any $h \in G$, a map $c_h : G \times G \to U(1)$ via

$$c_g(h_1, h_2) = \frac{\alpha(g, h_1, h_2)\alpha(h_1, h_2, (h_1 h_2)^{-1} g (h_1 h_2))}{\alpha(h_1, h_1^{-1} g h_1, h_2)} \ . \tag{A.9}$$

It is shown in [45] that c_g defines a 2-cocycle of the stabilizer subgroup $C_G(g) \subseteq G$ (i.e. the subgroup of all elements h_1, h_2 which commute with g). When $h_1, h_2 \in C_G(g)$, we have the simplified expression

$$c_g(h_1, h_2) = \frac{\alpha(g, h_1, h_2)\alpha(h_1, h_2, g)}{\alpha(h_1, g, h_2)} \ , \qquad h_1, h_2 \in C_G(g) \ . \tag{A.10}$$

It is straightforward to check this by inserting (A.9) into (A.1), and making repeated use of the 3-cocycle condition (A.4) (twice on each side of the equality sign) together with the fact that g commutes with h_1, h_2, h_3.

Under the 'gauge transformation' (A.5), c_g transforms as

$$c_g(h_1, h_2) \to \tilde{c}_g(h_1, h_2) := c_g(h_1, h_2)\frac{\gamma_g(h_1)\gamma_g(h_2)}{\gamma_g(h_1 h_2)} \ , \qquad h_1, h_2 \in C_G(g) \ , \tag{A.11}$$

where we defined the 1-cochain γ_g by

$$\gamma_g(h) \equiv \frac{\beta(g, h)}{\beta(h, g)} \ . \tag{A.12}$$

This is indeed of the form (A.2), and hence, for all $g \in G$, c_g defines a map

$$c_g \ : \ H^3(G, U(1)) \ \to H^2(C_G(g), U(1)) \ . \tag{A.13}$$

In fact, if c_g is the 2-cocycle associated to a projective representation ρ_g of $C_G(g)$, i.e.

$$\rho_g(h_1)\rho_g(h_2) = c_g(h_1, h_2)\rho_g(h_1 h_2) \ , \tag{A.14}$$

then $\tilde{c}_g$ is the 2-cocycle associated with the projectively equivalent representation

$$\tilde{\rho}_g(h) := \gamma_g(h)\rho_g(h) \ . \tag{A.15}$$

In the context of holomorphic CFTs, the transformation (A.5) corresponds to a redefinition (A.15) of the projective representations ρ_g of the centralizer $C_G(g)$ over the twisted sector $\mathcal{H}_g$, which induces the analogous transformation of the twisted twining partition functions

$$Z_{g,h} \to \tilde{Z}_{g,h} = \gamma_g(h) Z_{g,h} \ . \tag{A.16}$$

Indeed, the new partition functions $\tilde{Z}_{g,h}$ satisfy the expected modular properties with respect to the new cocycle $\tilde{\alpha}$.

In particular, it the case (A.7) of conjugation by $x \in G$, we have $\beta \equiv \eta_x^{-1}$, so that

$$\gamma_g(h) = \frac{\eta_x(h,g)}{\eta_x(g,h)} = \frac{c_g(x, x^{-1}hx)}{c_g(h,x)} \ , \qquad h \in C_g(G) \ , \tag{A.17}$$

where the latter equality follows from [46, 47]. From this identity, one recovers

$$Z_{(\mathbb{I},x^{-1})\cdot(g,h)}(\tau) \equiv Z_{x^{-1}gx, x^{-1}hx}(\tau) = \frac{c_g(x, x^{-1}hx)}{c_g(h,x)} Z_{g,h}(\tau) \ , \tag{A.18}$$

from which the formula (B.8) for $\epsilon_{g,h}(\mathbb{I}, x)$ follows.

One further useful identity is [47]

$$\frac{c_{x_1 x_2}(z_1, z_2)}{c_{x_1}(z_1,z_2) c_{x_2}(z_1,z_2)} = \frac{c_{z_1}(x_1,x_2) c_{z_2}(x_1,x_2)}{c_{z_1 z_2}(x_1,x_2)} \ , \tag{A.19}$$

that holds for *pairwise commuting* $x_1, x_2, z_1, z_2 \in G$.

For most applications, only the restriction of a 3-cocycle α to subgroups of the form $\langle g, h\rangle \cong \mathbb{Z}_{N_1} \times \mathbb{Z}_{N_2}$ is needed. For such groups, we have $\mathcal{H}^3(\mathbb{Z}_{N_1} \times \mathbb{Z}_{N_2}, U(1)) = \mathbb{Z}_{N_1} \times \mathbb{Z}_{N_2} \times \mathbb{Z}_{\gcd(N_1,N_2)}$ and a set of normalized representatives for the generators are [73]

$$\alpha_{v_i}(g^{a_1}h^{a_2}, g^{b_1}h^{b_2}, g^{c_1}h^{c_2}) := e^{\frac{2\pi i v_i a_i}{N_i^2}([b_i]_{N_i} + [c_i]_{N_i} - [b_i + c_i]_{N_i})} \tag{A.20}$$

where $v_i \in \mathbb{Z}/N_i\mathbb{Z}$, $i = 1, 2$, and

$$\alpha_{v_{12}}(g^{a_1}h^{a_2}, g^{b_1}h^{b_2}, g^{c_1}h^{c_2}) := e^{\frac{2\pi i v_{12} a_1}{N_1 N_2}([b_2]_{N_2} + [c_2]_{N_2} - [b_2 + c_2]_{N_2})} \tag{A.21}$$

where $v_{12} \in \mathbb{Z}/\gcd(N_1,N_2)\mathbb{Z}$ and $[\cdot]_x : \mathbb{Z} \to \{0, \ldots, x-1\}$ denotes the reduction modulo x. Notice that, with this choice for the generators, we have the simplified formula

$$c_x(y,z) = \alpha(x,y,z) \ , \qquad x, y, z \in \mathbb{Z}_{N_1} \times \mathbb{Z}_{N_2} \ . \tag{A.22}$$

B Modular properties of twisted twining partition functions

In this appendix we include some details on the modular properties of twisted twining partition functions. In particular, we analyze the combined action of $SL(2,\mathbb{Z})$ and G on the set of commuting pairs (g,h) in G. Here we must also take into account the presence of a non-trivial 3-cocycle α which leads to a certain twisted action. We introduce a convenient "twisted equivariant slash-operator" that simplifies many expressions since it combines (twisted) $SL(2,\mathbb{Z})$-equivariance with G-equivariance. Finally, we discuss a reformulated version of the cohomological obstructions found in [17].

B.1 $SL(2,\mathbb{Z})\times G$ - action on $\mathcal{P}_G$

It is clear from (2.8) that modular transformations act on $\tau\in\mathbb{H}$ as well as on the set of commuting pairs $(g,h)\in G\times G$. In addition G acts on itself by conjugation and thereby on the set of pairs g,h. In order to determine the subgroups $\Gamma_{g,h}\subset SL(2,\mathbb{Z})$ under which $Z_{g,h}$ (and $\phi_{g,h}$) are invariant for fixed $g,h\in G$, we must classify the orbits of the combined $SL(2,\mathbb{Z})\times G$-action on the commuting pair (g,h). We are mainly interested in the case $G=M_{24}$ but we only make this specification at the end of the subsection.

For any finite group G, let $\mathcal{P}_G\subset G\times G$ be the set of commuting pairs of elements:

$$\mathcal{P}_G=\{(g,h)\in G\times G\mid gh=hg\}\ . \tag{B.1}$$

The group $SL(2,\mathbb{Z})\times G$ has a left action as a permutation over this set by

$$\left(\begin{pmatrix}a&b\\c&d\end{pmatrix},k\right)\cdot(g,h):=(k\,g\,k^{-1},k\,h\,k^{-1})\begin{pmatrix}a&b\\c&d\end{pmatrix}^{-1}=(kg^dh^{-c}k^{-1},kg^{-b}h^ak^{-1})\ , \tag{B.2}$$

where $(g,h)\in\mathcal{P}_G$, $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in SL(2,\mathbb{Z})$ and $k\in G$. This action can be extended to an action of $GL(2,\mathbb{Z})\times G$ in the obvious way.

B.2 Twisted action on $\mathcal{P}_G$: generalized permutation

As explained in section 2.2, in order to include the possibility of non-trivial multipliers in the modular properties of the twisted twining genera one needs to consider the "twisting" of the action (B.2) by a 3-cocycle α, representing a cohomology class in $H^3(G,U(1))$. This α-twisted action is a generalized permutation

$$\mathbb{C}\mathcal{P}_G\times SL(2,\mathbb{Z})\times G\to\mathbb{C}\mathcal{P}_G\ , \tag{B.3}$$

on the complex vector space $\mathbb{C}\mathcal{P}_G$ freely generated by the elements of $\mathcal{P}_G$. We define this action by the formula

$$(\gamma, k)_\alpha : (g, h) \mapsto \epsilon_{g,h}(\gamma, k)(kgk^{-1}, khk^{-1})\gamma^{-1} \ . \tag{B.4}$$

Here, $(\gamma, k) \in SL(2,\mathbb{Z}) \times G$ and $\epsilon_{g,h}(\gamma, k) \in U(1)$ is a phase which depends on the choice of 3-cocycle α. More precisely, in terms of the 2-cocycle $c_g(h_1, h_2)$ in (2.7) the phases $\epsilon_{g,h}(\gamma, k)$ are defined as

$$\epsilon_{g,h}(\gamma_1\gamma_2, k_1k_2) := \epsilon_{(\gamma_2,k_2)\cdot(g,h)}(\gamma_1, k_1)\ \epsilon_{g,h}(\gamma_2, k_2) \ , \tag{B.5}$$

$$\epsilon_{g,h}(T, e) := \frac{1}{c_g(g, g^{-1}h)} \ , \tag{B.6}$$

$$\epsilon_{g,h}(S, e) := c_g(h^{-1}, h) \ , \tag{B.7}$$

$$\epsilon_{g,h}(\mathbb{I}, k) := \frac{c_g(h, k^{-1})}{c_g(k^{-1}, khk^{-1})} \ , \qquad k \in G \ , \tag{B.8}$$

where

$$S := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \qquad\qquad T := \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \ , \tag{B.9}$$

are the generators of $SL(2,\mathbb{Z})$.

B.3 Modular properties of twisted twining partition functions

We now wish to analyze the modular properties of the twisted twining partition function $Z_{g,h}$ in more detail. To this end we define the following equivariant slash operator

$$f(g, h; \tau)|(\gamma, k) := f\big((\gamma, k) \cdot (g, h);\ \gamma \cdot \tau\big) \ , \qquad (\gamma, k) \in SL(2,\mathbb{Z}) \times G \ , \tag{B.10}$$

acting on modular functions $f : \mathcal{P}_G \times \mathbb{H}_+ \to \mathbb{C}$. We can think of the twisted twining partition functions $Z_{g,h}(\tau)$ as functions on $\mathcal{P}_G \times \mathbb{H}_+$ that are equivariant under $SL(2,\mathbb{Z}) \times G$, up to a multiplier. In the simplest case when the multiplier system is trivial, this property can be expressed as follows in terms of the slash operator:

$$Z_{g,h}(\tau)|(\gamma, k) = Z_{g,h}(\tau) \ . \tag{B.11}$$

In particular, for each fixed $(g, h) \in \mathcal{P}_G$, the function $Z_{g,h}(\tau)$ is a modular function under some subgroup $\Gamma_{g,h} \in PSL(2,\mathbb{Z})$, i.e.

$$Z_{g,h}(\gamma \cdot \tau) = Z_{g,h}(\tau) \ , \qquad \gamma \in \Gamma_{g,h} \subseteq PSL(2,\mathbb{Z}) \ . \tag{B.12}$$

The group $\Gamma_{g,h}$ is the image $\pi(\tilde{\Gamma}_{g,h})$ of the stabilizer

$$\tilde{\Gamma}_{g,h} := \{(\gamma, k) \in SL(2,\mathbb{Z}) \times G \mid (g,h) \cdot (\gamma, k) = (g,h)\} \ , \tag{B.13}$$

under the homomorphism

$$\pi : SL(2,\mathbb{Z}) \times G \to PSL(2,\mathbb{Z}) \ . \tag{B.14}$$

Similar properties hold for the twisted twining genera $\phi_{g,h}(\tau, z)$ of an $\mathcal{N} = (4,4)$ superconformal algebra: these are expected to be Jacobi forms of weight zero and index 1 with respect to the same groups $\Gamma_{g,h}$. For this reason, we need to extend the definition of the slash operator to an action on the space of functions $\psi : \mathcal{P}_G \times \mathbb{H}_+ \times \mathbb{C} \to \mathbb{C}$. Specifically, for Jacobi forms of weight 0 and index m with respect to some $\Gamma \subset SL(2,\mathbb{Z})$ we define

$$\psi(g,h;\tau,z)|\big(\gamma,k\big) := e^{-\frac{2\pi i m c z^2}{c\tau+d}} \psi\Big(k\, g^d h^{-c}\, k^{-1},\ k\, g^{-b} h^a\, k^{-1};\ \gamma\cdot\tau, \frac{z}{c\tau+d}\Big) \ , \tag{B.15}$$

where $(\gamma, k) = \big(\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right), k\big) \in SL(2,\mathbb{Z}) \times G$. Note that for theories with $\mathcal{N} = (4,4)$ superconformal symmetry, these genera are expected to be *even* functions of z, so that the central element $C = S^2 \in SL(2,\mathbb{Z})$ acts trivially and it makes sense to consider the action on such functions of the quotient $PSL(2,\mathbb{Z}) = SL(2,\mathbb{Z})/\mathbb{Z}_2$.

We are now ready to incorporate the α-twist in the modular properties of the twisted twining genera. To this end we define the α-twisted generalization of the equivariant slash operator:

$$f(g,h,\tau)|_\alpha(\gamma,k) := \epsilon_{g,h}(\gamma,k) f\big((\gamma,k)\cdot(g,h);\gamma\cdot\tau\big) \ , \qquad (\gamma,k) \in SL(2,\mathbb{Z}) \times G \ , \tag{B.16}$$

for some 3-cocycle α representing a class $[\alpha] \in H^3(G, U(1))$. Similarly, we define the α-twisted slash operators on Jacobi forms of weight 0 and index m by

$$\psi(g,h;\tau,z)|_\alpha\big(\gamma,k\big) := \epsilon_{g,h}(\gamma,k) e^{-\frac{2\pi i m c z^2}{c\tau+d}} \psi\Big(k\, g^d h^{-c}\, k^{-1},\ k\, g^{-b} h^a\, k^{-1};\ \gamma\cdot\tau, \frac{z}{c\tau+d}\Big) \ , \tag{B.17}$$

where $(\gamma, k) = \big(\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right), k\big) \in SL(2,\mathbb{Z}) \times G$.

B.4 Cohomological obstructions

When α represents a non-trivial class in $H^3(G, U(1))$, the partition functions $Z_{g,h}(\tau)$ are modular functions under $\Gamma_{g,h} \subseteq PSL(2,\mathbb{Z})$ only up to some multiplier $\chi_{g,h}$, which depends on α (see section 2.2). In fact, by (B.13) and (B.8), the restriction of $\epsilon_{g,h}$ to $\tilde{\Gamma}_{g,h}$ is a group homomorphism $\tilde{\Gamma}_{g,h} \to U(1)$. If

$$\epsilon_{g,h}(\gamma,k) = 1 \ , \tag{B.18}$$

for all (γ, k) in

$$\begin{aligned} \tilde{\Gamma}_{g,h} \cap \ker \pi = &\{(e,k) \in SL(2,\mathbb{Z}) \times G \mid (k^{-1}gk, k^{-1}hk) = (g,h)\} && \text{(B.19)} \\ &\cup \{(S^2,k) \in SL(2,\mathbb{Z}) \times G \mid (k^{-1}gk, k^{-1}hk) = (g^{-1},h^{-1})\} \ , && \text{(B.20)} \end{aligned}$$

then the restriction $\epsilon_{g,h} : \tilde{\Gamma}_{g,h} \to U(1)$ induces a well-defined homomorphism $\chi_{g,h} : \Gamma_{g,h} \to U(1)$ on the image $\Gamma_{g,h} = \pi(\tilde{\Gamma}_{g,h})$. Explicitly, for each $\gamma \in \Gamma_{g,h} \subseteq PSL(2,\mathbb{Z})$, one can choose a lift $(\gamma, k) \in \tilde{\Gamma}_{g,h} \subseteq SL(2,\mathbb{Z}) \times G$ and set

$$\chi_{g,h}(\gamma) := \epsilon_{g,h}(\gamma, k) \ , \qquad \text{for } \gamma = \pi(\gamma, k) \in \Gamma_{g,h} \ . \tag{B.21}$$

By (B.18), the definition is independent of the lift.

On the contrary, if (B.18) is not satisfied for some $(\gamma, k) \in \tilde{\Gamma}_{g,h} \cap \ker \pi$, then eq.(2.12) implies that $Z_{g,h}(\tau)$ must vanish identically. In this case, we say that the twisted twining partition function is *obstructed*. Following the discussion in [17, 18], we can distinguish between two kinds of obstructions:

(1) We say that, for a certain $(g,h) \in \mathcal{P}_G$, there is an obstruction of the *first kind* if there is some element of the form $(e,k) \in \tilde{\Gamma}_{g,h} \cap \ker \pi$ for which (B.18) is not satisfied.

(2) We say that there is an obstruction of the *second kind* if (B.18) is satisfied for all elements of the form $(e,k) \in \tilde{\Gamma}_{g,h} \cap \ker \pi$, but is violated by some element of the form $(S^2,k) \in \tilde{\Gamma}_{g,h} \cap \ker \pi$. By (B.8), this implies that (B.18) is false for *all* elements of the form $(S^2,k) \in \tilde{\Gamma}_{g,h} \cap \ker \pi$.

Although not phrased this way in [17] these obstructions are equivalent to the ones given there.

C Definition of twisted equivariant Hecke operators

In this appendix, we shall discuss the definition and properties of the α-twisted equivariant Hecke operators.

C.1 Twisted equivariant Hecke operator

Let us denote by $\mathrm{Mat}(\mathbb{Z})$ the ring of 2×2 integral matrices with positive determinant, graded by the determinant,

$$\mathrm{Mat}(\mathbb{Z}) = \bigcup_{L>0} \mathrm{Mat}_L(\mathbb{Z}) \ , \tag{C.1}$$

where $\mathrm{Mat}_L(\mathbb{Z})$ was defined in (3.4). For any $u \in \mathrm{Mat}_L(\mathbb{Z})$ denote by $u^\vee \in \mathrm{Mat}_L(\mathbb{Z})$ the dual

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^\vee := L \begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} , \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{Mat}_L(\mathbb{Z}) \ . \tag{C.2}$$

Note that $\mathrm{Mat}_1(2,\mathbb{Z}) \equiv SL(2,\mathbb{Z})$ is the group of invertible elements of $\mathrm{Mat}(\mathbb{Z})$ and that each $\mathrm{Mat}_L(\mathbb{Z})$ is a bimodule over $SL(2,\mathbb{Z})$.

In order to define the α-twisted equivariant Hecke operators $\mathcal{T}_L^\alpha$, we need to extend the action (B.3) of $SL(2,\mathbb{Z}) \times G$ on $\mathbb{C}\mathcal{P}_G$ to an action

$$\mathbb{C}\mathcal{P}_G \times \mathrm{Mat}(\mathbb{Z}) \times G \to \mathbb{C}\mathcal{P}_G \ , \tag{C.3}$$

by

$$(u,k)_\alpha : (g,h) \mapsto \epsilon_{g,h}(u,k)(kgk^{-1}, khk^{-1})u^\vee \ , \tag{C.4}$$

for a suitable $\epsilon_{g,h}(u,k) \in U(1)$, that reduces to the one discussed in section B.2 when $u \in \mathrm{Mat}_1(\mathbb{Z}) = SL(2,\mathbb{Z})$. Furthermore, the interpretation of $\phi_{g,h}$ as a section of $\mathcal{L}^\alpha_{g,h}$ suggests that the following composition law should be imposed

$$(u_1u_2, k_1k_2)_\alpha \cdot (g,h) = (u_1,k_1)_\alpha \cdot \big((u_2,k_2)_{\alpha^L} \cdot (g,h)\big) \ , \tag{C.5}$$

where $(u_1,k_1) \in \mathrm{Mat}_L(\mathbb{Z}) \times G$ and $(u_2,k_2) \in \mathrm{Mat}(\mathbb{Z}) \times G$. In terms of the phases $\epsilon_{g,h}$, this condition reads

$$\epsilon_{g,h}((u_1,k_1)\cdots(u_n,k_n)) = \prod_{i=1}^n \epsilon_{(u_{i+1},k_{i+1})\cdots(u_n,k_n)\cdot(g,h)}(u_i,k_i)^{|u_1\cdots u_{i-1}|} \ , \tag{C.6}$$

where $|u_i| := \det u_i$.

Observe that $\mathrm{Mat}(\mathbb{Z})$, as a multiplicative semigroup, is generated by $SL(2,\mathbb{Z})$ together with the matrices of the form $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ for p prime. Therefore, it is sufficient to specify the phases $\epsilon((\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}), e)$ for all primes p and any other phase $\epsilon_{g,h}(u,k)$, $(u,k) \in \mathrm{Mat}(\mathbb{Z}) \times G$, is then determined by (C.6). The α-twisted slash operator (2.15) can be trivially extended to an action with respect to $\gamma \in \mathrm{Mat}_L(\mathbb{Z})$, in which case it maps a Jacobi form ϕ of weight 0 and index m to another Jacobi form $\phi|_\alpha(\gamma,k)$ of weight 0 and index Lm. Notice that, by (C.6), the twisted slash operators satisfy the composition relation

$$|_\alpha(u_1u_2, k_1k_2) = |_\alpha(u_1,k_1)|_{\alpha^L}(u_2,k_2) \tag{C.7}$$

We can now define the α-twisted equivariant Hecke operators acting on the space of $SL(2,\mathbb{Z}) \times G$-equivariant Jacobi forms $\phi_{g,h}$ by

$$\mathcal{T}_L^\alpha \phi_{g,h}(\tau,z) := \frac{1}{L} \sum_{u \in SL(2,\mathbb{Z}) \backslash \mathrm{Mat}_L(\mathbb{Z})} \phi_{g,h}(\tau,z)|_\alpha(u,e) \ , \tag{C.8}$$

$$\mathcal{U}_L^\alpha \phi_{g,h}(\tau,z) := \phi_{g,h}(\tau,z)|_\alpha(\begin{smallmatrix} L & 0 \\ 0 & L \end{smallmatrix}, e) \ . \tag{C.9}$$

One may check that these operators satisfy the Hecke algebra (3.13)–(3.16). Furthermore, $\mathcal{T}_L^\alpha$ (respectively, $\mathcal{U}_L^\alpha$) maps the system of α-twisted $SL(2,\mathbb{Z})\times G$-equivariant (weak) Jacobi forms of weight 0 and index m to a system of α^L-twisted (respectively, α^{L^2}-twisted) $SL(2,\mathbb{Z})\times G$-equivariant (weak) Jacobi forms of weight 0 and index Lm (respectively, index L^2m). The proofs of these properties are completely analogous to the case where α is trivial; in fact, these properties follow directly from the definition of the Hecke operators in terms of slash operators satisfying a composition law of the form (C.7).

C.2 Definition of slash operator for $\mathrm{Mat}(\mathbb{Z})\times G$

In this subsection, we will describe the extension of the α-twisted slash operators to $\mathrm{Mat}(\mathbb{Z})\times G$. As stressed in section 3.2, it is sufficient to define such operators for matrices of the form $\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right)$, since, together with $SL(2,\mathbb{Z})$ they generate the whole $\mathrm{Mat}(\mathbb{Z})$. We will make an ansatz for the phase $\epsilon_{g,h}\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big)$ and verify that it extends consistently to the whole $\mathrm{Mat}(\mathbb{Z})$.

Our ansatz for the phase $\epsilon_{g,h}\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big)$ is based on the interpretation of the corresponding slash operator within the theory of symmetric orbifolds of conformal field theories. We recall that the twisted twining partition function $Z_{g,h}(\tau)$ in a holomorphic CFT is defined as a trace $\mathrm{Tr}_{\mathcal{H}_g}(\rho_g(h)q^{L_0-\frac{c}{24}})$, where $\mathcal{H}_g$ is the g-twisted sector and ρ_g is the (possibly projective) representation of the centralizer $C_G(g)$ on $\mathcal{H}_g$. This partition function can be computed by a path integral on a torus $\mathbb{C}/(\mathbb{Z}+\tau\mathbb{Z})$ where the fields are required to have monodromies g and h along the cycles -1 and τ, respectively. The function

$$Z_{g,h}(\tau)|_\alpha\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big) = \Upsilon^*_{\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right)} Z_{g,h}\ , \tag{C.10}$$

is associated with the L-fold covering $\mathbb{C}/(\mathbb{Z}+L\tau\mathbb{Z})$ and has a natural interpretation as a trace

$$Z_{g,h}(\tau)|_\alpha\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big) = \mathrm{Tr}_{\mathcal{H}_g}\big((\rho_g(h)q^{L_0-\frac{c}{24}})^L\big)\ . \tag{C.11}$$

Using the product law (2.5) for the projective representation ρ_g, we obtain

$$Z_{g,h}(\tau)|_\alpha\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big) = \prod_{i=1}^{L-1} c_g(h,h^i)\,\mathrm{Tr}_{\mathcal{H}_g}(\rho_g(h^L)q^{LL_0-\frac{Lc}{24}}) = \prod_{i=1}^{L-1} c_g(h,h^i) Z_{g,h^L}(L\tau)\ . \tag{C.12}$$

This formula suggests the definition

$$\epsilon_{g,h}\big(\left(\begin{smallmatrix} L & 0\\ 0 & 1\end{smallmatrix}\right), e\big) = \prod_{i=1}^{L-1} c_g(h,h^i)\ , \tag{C.13}$$

so that

$$f(g,h;\tau)|_\alpha\big(\left(\begin{smallmatrix} L & 0 \\ 0 & 1\end{smallmatrix}\right),e\big)=\prod_{i=1}^{L-1}c_g(h,h^i)f\Big((g,h)\left(\begin{smallmatrix} 1 & 0 \\ 0 & L\end{smallmatrix}\right);\,\left(\begin{smallmatrix} L & 0 \\ 0 & 1\end{smallmatrix}\right)\cdot\tau\Big)\ , \tag{C.14}$$

Any integer matrix of determinant L can be written as a product of elements in $SL(2,\mathbb{Z})$ and matrices of the form $\left(\begin{smallmatrix} p & 0 \\ 0 & 1\end{smallmatrix}\right)$ for prime p. For each $(u,k)\in\mathrm{Mat}(\mathbb{Z})\times G$, given a representation of u as a word $u=a_1\cdots a_n$ in the generators $a_1,\ldots,a_n$ of $\mathrm{Mat}(\mathbb{Z})$, one can use the composition law

$$f(g,h;\tau)|_\alpha(u_1u_2,k_1k_2)=f(g,h;\tau)|_\alpha(u_1,k_1)\ |_{\alpha^{|u_1|}}(u_2,k_2)\ , \tag{C.15}$$

where $|u|:=\det u$, to define the slash operator

$$f(g,h;\tau)|_\alpha(a_1\cdots a_n,k):=f(g,h;\tau)|_\alpha(\mathbb{I},k)\ |_\alpha(a_1,e)\ |_{\alpha^{|a_1|}}(a_2,e)\ \cdots\ |_{\alpha^{|a_1\cdots a_{n-1}|}}(a_n,e)\ . \tag{C.16}$$

One needs to check that this definition is consistent, i.e. that the operator $|_\alpha(u,k)$ does not depend on representation of $(u,k)\in\mathrm{Mat}(\mathbb{Z})\times G$ as a word in the generators and that the composition law is respected. The outline of the proof is given in the next subsection.

In particular, by (C.15), the identity

$$\begin{pmatrix}1 & 0\\ 0 & L\end{pmatrix}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}L & 0\\ 0 & 1\end{pmatrix}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix} \tag{C.17}$$

yields

$$\epsilon_{g,h}\big(\left(\begin{smallmatrix} 1 & 0 \\ 0 & L\end{smallmatrix}\right),e\big)=\frac{c_g(h^{-1},h)^L\prod_{i=1}^{L-1}c_{h^{-1}}(g,g^i)}{c_{g^L}(h^{-1},h)}=\frac{1}{\prod_{i=1}^{L-1}c_h(g,g^i)}\ , \tag{C.18}$$

where in the last step we use (A.19), while from the identity

$$\begin{pmatrix}a & b\\ 0 & d\end{pmatrix}=\begin{pmatrix}1 & 0\\ 0 & d\end{pmatrix}\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}^b\begin{pmatrix}a & 0\\ 0 & 1\end{pmatrix} \tag{C.19}$$

we obtain the general formula

$$\epsilon_{g,h}\left(\begin{smallmatrix} a & b \\ 0 & d\end{smallmatrix}\right):=\epsilon_{g,h}\big(\left(\begin{smallmatrix} a & b \\ 0 & d\end{smallmatrix}\right),e\big)=\frac{\prod_{i=1}^{a-1}c_g(h,h^i)^d}{\prod_{j=1}^{d-1}c_{g^{-b}h^a}(g,g^j)\prod_{k=1}^{b}c_g(g,g^{-k}h^a)^d}\ . \tag{C.20}$$

Since for any coset of $SL(2,\mathbb{Z})\backslash\,\mathrm{Mat}(\mathbb{Z})$ we can choose a representative of the form $\left(\begin{smallmatrix} a & b \\ 0 & d\end{smallmatrix}\right)$, this formula is sufficient to determine the Hecke operators $\mathcal{T}_L^\alpha$ and $\mathcal{U}_L^\alpha$ for all L. In particular, if the restriction of the 3-cocycle α to the group $\langle g,h\rangle\cong\mathbb{Z}_{N_1}\times\mathbb{Z}_{N_2}$ is given by $\alpha=\alpha_{v_1}\alpha_{v_2}\alpha_{v_{12}}$, in terms of the generators (A.20)–(A.21), then $(N_1,N_2>1)$

$$\epsilon_{g,h}\big(\left(\begin{smallmatrix} a & b \\ 0 & d\end{smallmatrix}\right),e\big)=e^{\frac{2\pi i}{N_1}\left(v_1b\sum_{j=1}^{d-1}\delta^{(N_1)}(j+1)-v_1d\sum_{j=1}^{b}\delta^{(N_1)}(1-j)+v_{12}d\sum_{j=1}^{a-1}\delta^{(N_2)}(j+1)\right)}\ . \tag{C.21}$$

C.3 Proof of consistency

In the rest of this section, we will show that our proposal for the twisted equivariant Hecke operators satisfies several consistency conditions. As a first consistency, let us consider the effect of a 'gauge transformation' (A.5), under which the normalized 3-cocycle α is multiplied by a 3-coboundary $\partial\beta$ (with $\beta(e,g)=\beta(g,e)=1$ to keep the normalization). Formally, this transformation corresponds to a different choice of trivialization of the pull-back $\pi^*\mathcal{L}^\alpha_{g,h}$, where $\pi:\mathcal{P}\times\mathbb{H}_+\times\mathbb{C}\to\mathcal{M}$ is the covering map. As stressed in the previous appendix A, for a holomorphic CFTs $\mathcal{C}$, the transformation (A.5) corresponds to a redefinition (A.15) of the projective representations ρ_g of the centralizer $C_G(g)$ over the twisted sector $\mathcal{H}_g$ and induces the transformation (A.16) of the partition functions. For the tensor product $\mathcal{C}^{\otimes L}$ and the symmetric product $S^L\mathcal{C}$ theories, the twisted twining partition functions $Z_{g,h}$ are defined as traces over the representation induced by the (symmetrized) L-tensor product of ρ_g, so that the appropriate transformation is

$$Z^{(L)}_{g,h}\mapsto\tilde{Z}^{(L)}_{g,h}:=\gamma_g(h)^L Z^{(L)}_{g,h}\ , \tag{C.22}$$

where $\gamma_g(h)=\beta(g,h)/\beta(h,g)$. Analogous properties hold for the twisted twining genera $\phi^{(L)}_{g,h}$ in superconformal field theories. Using the identities $\gamma_e(g)=\gamma_g(e)=1$ and $\gamma_g(h)=\gamma_h(g)^{-1}$, it is easy to check that, under (A.15) and (A.11),

$$\big(\gamma_g(h)f(g,h;\tau)\big)|_{\tilde\alpha}\big(\left(\begin{smallmatrix}a&b\\0&d\end{smallmatrix}\right)\gamma,e\big)=\gamma_g(h)^L\Big(f(g,h;\tau)|_\alpha\big(\left(\begin{smallmatrix}a&b\\0&d\end{smallmatrix}\right)\gamma,e\big)\Big)\ , \tag{C.23}$$

where $L=ad$, and similar properties hold for Jacobi forms. As a consequence, we obtain

$$\mathcal{T}^{\tilde\alpha}_L\tilde{Z}_{g,h}=\gamma_g(h)^L\mathcal{T}^\alpha_L Z_{g,h}\ , \tag{C.24}$$

and

$$\mathcal{T}^{\tilde\alpha}_L\tilde\phi_{g,h}=\gamma_g(h)^L\mathcal{T}^\alpha_L\phi_{g,h}\ ,\qquad \mathcal{U}^{\tilde\alpha}_L\tilde\phi_{g,h}=\gamma_g(h)^{L^2}\mathcal{U}^\alpha_L\phi_{g,h}\ , \tag{C.25}$$

which indeed reproduce (C.22) and the analogous formula for twisted twining genera. More generally, given *any* representation of a matrix $u\in\mathrm{Mat}_L(\mathbb{Z})$ as a word in the generators of $\mathrm{Mat}(\mathbb{Z})$, it is easy to check that (C.23) holds for the slash operator $|_\alpha(u,k)$, i.e

$$\gamma_g(h)\tilde\epsilon_{g,h}(u,k)=\gamma_g(h)^L\epsilon_{g,h}(u,k)\ . \tag{C.26}$$

An easy corollary of this property is

$$f(g,h;\tau)|_\alpha(u,k)|_{\alpha^L}(\mathbb{I},x)=f(g,h;\tau)|_\alpha(\mathbb{I},x)|_\alpha(u,k)\ ,\qquad (u,k)\in\mathrm{Mat}_L(\mathbb{Z})\times G,\ x\in G\ , \tag{C.27}$$

which follows by considering (C.26) for the transformation (A.7). As a consequence of (C.27), one only needs to prove consistency of the slash operator for elements of the form (u, e).

A set of generators of the multiplicative semigroup $\mathrm{Mat}(\mathbb{Z})$ is given by the generators S, T of $SL(2,\mathbb{Z})$ (see eq.(B.9)), together with all matrices $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ for p prime. To check the consistency of the definition of the slash operator, one needs to verify that, for each relation $a_1 \cdots a_n = b_1 \cdots b_m$ among the generators of $\mathrm{Mat}(\mathbb{Z})$, the following identities hold for all $(g, h) \in \mathcal{P}_G$

$$f(g,h;\tau)|_\alpha (a_1, e) \cdots |_{\alpha^{|a_1 \cdots a_{n-1}|}} (a_n, e) = f(g,h;\tau)|_\alpha (b_1, e) \cdots |_{\alpha^{|b_1 \cdots b_{m-1}|}} (b_m, e) \ . \tag{C.28}$$

This is equivalent to checking the following identities for the phases

$$\prod_{i=1}^{n} \epsilon_{(g,h)a_{i+1}^\vee \cdots a_n^\vee}(a_i, e)^{|a_1 \cdots a_{i-1}|} = \prod_{i=1}^{m} \epsilon_{(g,h)b_{i+1}^\vee \cdots b_m^\vee}(b_i, e)^{|b_1 \cdots b_{i-1}|} \ . \tag{C.29}$$

For the relations $S^4 = 1$ and $(ST)^3 = S^2$ within $SL(2,\mathbb{Z})$, these conditions follow from the identities in [46, 47]; therefore, we will only consider the independent relations within $\mathrm{Mat}_L(\mathbb{Z})$ for $L > 1$.

For each prime power p, the relations within $\mathrm{Mat}_p(\mathbb{Z})$ can be obtained from the relations for $SL(2,\mathbb{Z})$, together with relations of the form

$$\gamma_1 \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \gamma_2 \ , \tag{C.30}$$

for suitable $\gamma_1, \gamma_2 \in SL(2,\mathbb{Z})$. It is easy to check that such a relation exists if and only if γ_2 is an element of $\Gamma_0(p)$, which is generated by T, S^2 and $ST^pS = \left(\begin{smallmatrix} 1 & 0 \\ -p & 1 \end{smallmatrix}\right)$. Therefore, the only independent relations within $\mathrm{Mat}_p(\mathbb{Z})$ are

$$T^p \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} T \ , \tag{C.31}$$

$$S^2 \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} S^2 \ , \tag{C.32}$$

and

$$STS \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} ST^pS \ . \tag{C.33}$$

The only remaining relations in $\mathrm{Mat}(\mathbb{Z})$ are of the form

$$\begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \gamma_1 \begin{pmatrix} p' & 0 \\ 0 & 1 \end{pmatrix} = \gamma_2 \begin{pmatrix} p' & 0 \\ 0 & 1 \end{pmatrix} \gamma_3 \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \gamma_4 \ , \tag{C.34}$$

for all pairs of distinct primes p, p' and suitable $\gamma_1, \gamma_2, \gamma_3, \gamma_4 \in SL(2,\mathbb{Z})$. In fact, it is easier to consider formula (C.20) as a definition of $\epsilon_{g,h}((\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}), e)$ and verify the identities (C.29) for the relations

$$\begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} pa & b \\ 0 & d \end{pmatrix} , \tag{C.35}$$

$$\begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} = \begin{pmatrix} pa & pb \\ 0 & d \end{pmatrix} , \tag{C.36}$$

since the consistency conditions for the relations (C.34) then follow. The consistency conditions are therefore

$$\epsilon_{g,h^p}\big(\begin{smallmatrix} 1 & p \\ 0 & 1 \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big) = \epsilon_{g,g^{-1}h}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\big)^p \tag{C.37}$$

$$\epsilon_{h^{-p},g}\big(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\big)\epsilon_{g,h^p}\big(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big) = \epsilon_{g^{-1},h^{-1}}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big)\epsilon_{h^{-1},p}\big(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\big)^p\epsilon_{g,h}\big(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\big)^p \tag{C.38}$$

$$\epsilon_{g^p,h}\big(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} 1 & 0 \\ 0 & p \end{smallmatrix}\big) = \epsilon_{g,g^{-p}h}\big(\begin{smallmatrix} 1 & 0 \\ 0 & p \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} 1 & p \\ 0 & 1 \end{smallmatrix}\big)^p \tag{C.39}$$

$$\epsilon_{g,h^p}\big(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big)^{ad} = \epsilon_{g,h}\big(\begin{smallmatrix} pa & b \\ 0 & d \end{smallmatrix}\big) \tag{C.40}$$

$$\epsilon_{g^d,g^{-b}h^a}\big(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\big)\epsilon_{g,h}\big(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\big)^p = \epsilon_{g,h}\big(\begin{smallmatrix} pa & pb \\ 0 & d \end{smallmatrix}\big) . \tag{C.41}$$

The proof is a tedious but straightforward computation, consisting of a repeated use of the cocycle conditions. For example, the proof of (C.40):

$$\begin{aligned} &\frac{\prod_{i=1}^{a-1} c_g(h,h^{ip})^d}{\prod_{j=1}^{d-1} c_{g^{-b}h^{ap}}(g,g^j)\prod_{k=1}^{b} c_g(g,g^{-k}h^{ap})^d} \prod_{i=1}^{p-1} c_g(h,h^i)^{ad} \frac{\prod_{j=1}^{d-1} c_{g^{-b}h^{ap}}(g,g^j)\prod_{k=1}^{b} c_g(g,g^{-k}h^{ap})^d}{\prod_{i=1}^{pa-1} c_g(h,h^i)^d} \\ &= \Big(\frac{\prod_{i=1}^{a-1} c_g(h,h^{ip})\prod_{i=1}^{p-1} c_g(h,h^i)^a}{\prod_{i=1}^{pa-1} c_g(h,h^i)}\Big)^d = 1 \end{aligned} \tag{C.42}$$

where the last equality follows from the 2-cocycle condition on c_g.

D Some technical proofs

D.1 Proof of (3.47).

In this section, we will prove eq.(3.47). The sum $F_{g,h}(a,d,k,\ell)$ can be written as

$$F_{g,h}(a,d,k,\ell) := \sum_{n=0}^{\infty} \frac{1}{d} \sum_{b=0}^{d-1} e^{\frac{2\pi i b n}{N\lambda d}} c_{g_\alpha^d, g_\alpha^{-b} h_\alpha^k}\big(\frac{n}{N\lambda}, \ell\big) q^{\frac{na}{N\lambda d}} , \tag{D.1}$$

in terms of the Fourier coefficients of the twisted twining genera $\phi_{g_\alpha^d, g_\alpha^{-b} h_\alpha^k}$ introduced in section 3.2.3. Notice that the functions $\phi_{g_\alpha, h_\alpha}$ satisfy

$$\phi_{g_\alpha^r, g_\alpha^{-r} h_\alpha}(\tau+1, z) = \phi_{g_\alpha^r, h_\alpha}(\tau, z) \ , \tag{D.2}$$

so that

$$c_{g_\alpha^d, g_\alpha^d h_\alpha}(r, \ell) = e^{\frac{2\pi i r}{N\lambda}} c_{g_\alpha^d, h_\alpha}(r, \ell) \ , \tag{D.3}$$

for all $h_\alpha \in C^\alpha_{M_{24}}(g)$. Set

$$e := \gcd(d, N\lambda) \ , \qquad f := \frac{d}{e} \ , \tag{D.4}$$

and note that

$$\gcd(f, \frac{N\lambda}{e}) = 1 \ , \tag{D.5}$$

otherwise $e \gcd(f, \frac{N\lambda}{e})$ would be a common divisor of d and $N\lambda$ greater than e. The order of g_α^d is $o(g_\alpha^{ef}) = o(g_\alpha^e) = N\lambda/e$, so that $c_{g_\alpha^d, g_\alpha^{-b} h_\alpha^k}(\frac{n}{N\lambda}, \ell) = 0$ unless $e|n$. Thus, we can set $r := n/e$ and obtain

$$F_{g,h}(a, d, k, \ell) = \sum_{r=0}^{\infty} \frac{1}{d} \sum_{b=0}^{d-1} e^{\frac{2\pi i b r e}{N\lambda d}} c_{g_\alpha^d, g_\alpha^{-b} h_\alpha^k}(\frac{re}{N\lambda}, \ell) q^{\frac{ar}{N\lambda f}} \ . \tag{D.6}$$

Notice that, by (D.3), the general term of the sum over b is periodic under $b \to b+d$. We can set $b := se + b'$ and replace the sum over $b \in \mathbb{Z}/d\mathbb{Z}$ by a sum over $b' \in \mathbb{Z}/e\mathbb{Z}$ and $s \in \mathbb{Z}/f\mathbb{Z}$

$$F_{g,h}(a, d, k, \ell) = \sum_{r=0}^{\infty} \frac{1}{e} \sum_{b'=0}^{e-1} \frac{1}{f} \sum_{s=0}^{f-1} e^{\frac{2\pi i (b'+se) r}{N\lambda f}} c_{g_\alpha^d, g_\alpha^{-b'} g_\alpha^{-se} h_\alpha^k}(\frac{re}{N\lambda}, \ell) q^{\frac{ar}{N\lambda f}} \ . \tag{D.7}$$

Thus, the general term of the sum over b' is periodic under $b' \to b' + e$ and we can sum over $N\lambda/e$ periods and divide by $N\lambda/e$

$$F_{g,h}(a, d, k, \ell) = \sum_{r=0}^{\infty} \frac{1}{N\lambda} \sum_{b'=0}^{N\lambda-1} \frac{1}{f} \sum_{s=0}^{f-1} e^{\frac{2\pi i (b'+se) r}{N\lambda f}} c_{g_\alpha^d, g_\alpha^{-b'} g_\alpha^{-se} h_\alpha^k}(\frac{re}{N\lambda}, \ell) q^{\frac{ar}{N\lambda f}} \ . \tag{D.8}$$

By (D.5), there are integers x, y such that

$$xf + y\frac{N\lambda}{e} = 1 \tag{D.9}$$

so that $se = sxd + syN\lambda$ and we obtain

$$\begin{aligned} F_{g,h}(a, d, k, \ell) =& \sum_{r=0}^{\infty} \frac{1}{N\lambda} \sum_{b'=0}^{N\lambda-1} \frac{1}{f} \sum_{s=0}^{f-1} e^{\frac{2\pi i b' r}{N\lambda f}} e^{\frac{2\pi i s (xd + yN\lambda) r}{N\lambda f}} c_{g_\alpha^d, g_\alpha^{-b'} g_\alpha^{-sdx} h_\alpha^k}(\frac{re}{N\lambda}, \ell) q^{\frac{ar}{N\lambda f}} \\ =& \sum_{r=0}^{\infty} \sum_{b'=0}^{N\lambda-1} \frac{e^{\frac{2\pi i b' r}{N\lambda f}}}{N\lambda} \sum_{s=0}^{f-1} \frac{e^{\frac{2\pi i s y r}{f}}}{f} c_{g_\alpha^d, g_\alpha^{-b'} h_\alpha^k}(\frac{re}{N\lambda}, \ell) q^{\frac{ar}{N\lambda f}} \ , \end{aligned} \tag{D.10}$$

where in the last step we used (D.3). Since by (D.9) $\gcd(y,f)=1$, the sum over s just a projection

$$\sum_{s=0}^{f-1}\frac{e^{\frac{2\pi i s y r}{f}}}{f}=\begin{cases}1 & \text{if } f|r\ ,\\ 0 & \text{otherwise}\ ,\end{cases} \tag{D.11}$$

so that, by setting $r=mf$, we obtain

$$F_{g,h}(a,d,k,\ell)=\sum_{m=0}^{\infty}\sum_{b'=0}^{N\lambda-1}\frac{e^{\frac{2\pi i b' m}{N\lambda}}}{N\lambda}c_{g_\alpha^d,g_\alpha^{-b'}h_\alpha^k}(\frac{md}{N\lambda},\ell)q^{\frac{am}{N\lambda}}\ , \tag{D.12}$$

that is equivalent to (3.47).

D.2 Central extensions and special choices of the cocycle

In section 3.2.3 a central extension $C^\alpha_{M_{24}}(g)$ of the centralizer $C_{M_{24}}(g)$ is defined, together with the representations $\tilde\rho_{g,r}$ on the g^r-twisted sector $\mathcal{H}_{g^r}$, for all $r\in\mathbb{Z}_{\geq 0}$. In this section, we will describe some special choices of the cocycle α, for which these representations are particularly simple.

If two 3-cocycles α, α' differ by a coboundary $\partial\beta$, then there is an isomorphism $C^{\alpha'}_{M_{24}}(g)\xrightarrow{\cong}C^\alpha_{M_{24}}(g)$ that relates the canonical lifts

$$h_{\alpha'}\mapsto h_\alpha\, q(\nu_g(h))\ , \tag{D.13}$$

where $\nu_g(h)\in\mathbb{R}/\mathbb{Z}$ is defined by $e^{2\pi i\nu_g(h)}=\frac{\beta(g,h)}{\beta(h,g)}$.

Under the shift $\alpha\to\alpha'$ by a coboundary $\partial\beta$, the cocycle c_g transforms as

$$c_g(h,k)\to\frac{\beta(g,h)}{\beta(h,g)}\frac{\beta(g,k)}{\beta(k,g)}\frac{\beta(hk,g)}{\beta(g,hk)}c_g(h,k)\ ,\qquad h,k\in C_{M_{24}}(g)\ . \tag{D.14}$$

Correspondingly, the phases $f_{g,r}(h)$ of eq.(3.31) transform as

$$f_{g,r}(h)\to f_{g,r}(h)\frac{\beta(h,g)^r}{\beta(g,h)^r}\frac{\beta(g^r,h)}{\beta(h,g^r)}\ ,\qquad h\in C_{M_{24}}(g)\ , \tag{D.15}$$

and, in particular,

$$f_{g,N}(h)\to f_{g,N}(h)\frac{\beta(h,g)^N}{\beta(g,h)^N}\ ,\qquad h\in C_{M_{24}}(g)\ . \tag{D.16}$$

Therefore, we can choose $\beta(g,h)/\beta(h,g)$ for each $h\in C_{M_{24}}(g)$, $h\notin\langle g\rangle$, in such a way that

$$f_{g,N}(h)=1\ ,\qquad \forall h\in C_{M_{24}}(g)\setminus\langle g\rangle\ . \tag{D.17}$$

This condition determines $\beta(g,h)/\beta(h,g)$ for all $h \in C_{M_{24}}(g) \setminus \langle g \rangle$ up to N-th roots of unity. Notice that, in general,

$$\tilde{\rho}_{g,r+N}(h) = \frac{\rho_{g^r}(h)}{f_{g,r}(h) f_{g,N}(h)} = \frac{\tilde{\rho}_{g^r}(h)}{f_{g,N}(h)} \ , \qquad h \in C_{M_{24}}(g) \ , \tag{D.18}$$

so that, by imposing (D.17), we have

$$\tilde{\rho}_{g,r+N}(h) = \tilde{\rho}_{g^r}(h) \ , \qquad h \in C_{M_{24}}(g) \setminus \langle g \rangle \ . \tag{D.19}$$

On the other hand, $f_{g,N}(g)$ depends only on the cohomology class $[\alpha]$. Since the restriction of $[\alpha]^N$ to $H^3(\langle g \rangle, U(1)) \cong \mathbb{Z}_N$ is the trivial class, it follows that $f_{g,N}(g)$ must be a N-th root of unity. In fact, for M_{24}, we have

$$f_{g,N}(g) = e^{-\frac{2\pi i}{\lambda}} \ , \tag{D.20}$$

where $\lambda | N$ is the length of the shortest cycle of g in the 24-dimensional permutation representation. It is also related to the spectrum of $L_0 - \frac{c}{24}$ in the g-twisted sector, which takes values in $-\frac{1}{\lambda N} + \frac{1}{N}\mathbb{Z}$ and to the presence of a non-trivial multiplier system for the twining genus $\phi_{e,g}$. It is useful to distinguishes the cases when $\lambda = 1$ and $\lambda \neq 1$.

D.2.1 Case $\lambda = 1$ (trivial multiplier)

This case occurs whenever g is an element of some M_{23} subgroup of M_{24}, i.e. when g belongs to the classes

$$2A,\ 3A,\ 4B,\ 5A,\ 6A,\ 7A,\ 7B,\ 8A,\ 11A,\ 14A,\ 14B,\ 15A,\ 15B,\ 23A,\ 23B \ .$$

In this case the restriction of $[\alpha]$ to $H^3(\langle g \rangle, U(1))$ is the trivial class and one can choose $\beta(g^i, g^j)$ in such a way that

$$c_{g^i}(g^j, g^k) = 1 \ . \tag{D.21}$$

In particular,

$$f_{g,r}(g^i) = 1 \ , \tag{D.22}$$

for all r, i. By specializing (3.32) to the case $r = N$, we obtain

$$c_g(h,k)^N = c_{g^N}(h,k) \frac{f_{g,N}(hk)}{f_{g,N}(h) f_{g,N}(k)} = 1 \ , \qquad h,k \in C(g) \ , \tag{D.23}$$

so that $c_g(h,k)$ is an N-th root of unity for all $h,k \in C_{M_{24}}(g)$, i.e. there is $\mu_g(h,k) \in \mathbb{Z}/N\mathbb{Z}$ such that

$$c_g(h,k) = e^{\frac{2\pi i \mu_g(h,k)}{N}} \ . \tag{D.24}$$

With this choice of cocycle, the central extension $C^{\alpha}_{M_{24}}(g)$ of section 3.2.3 can be chosen to be finite

$$1 \to \langle Q \rangle \cong \mathbb{Z}_N \to C^{\alpha}_{M_{24}}(g) \to C_{M_{24}}(g) \to 1 \ . \tag{D.25}$$

where the central element Q is related to the $U(1)$-generator $q(x)$ in section 3.2.3 by

$$Q = q(1/N) \ . \tag{D.26}$$

D.2.2 Case $\lambda \neq 1$ (non-trivial multiplier)

This case occurs when g is in one of the M_{24}-classes

$$2B,\ 3B,\ 4A,\ 4C,\ 6B,\ 10A,\ 12A,\ 12B,\ 21A,\ 21B \ .$$

Since $H^3(\langle g \rangle, U(1)) \cong \mathbb{Z}_N$, we can choose the cocycle in such a way that

$$c_{g^i}(g^j, g^k)^N = 1 \ , \tag{D.27}$$

for all $i, j, k \in \mathbb{Z}$. This condition fixes $\beta(g^i, g^j)$ up to N-th roots of unity. For $h, k \in C_{M_{24}}(g)$, with $h, k, hk \notin \langle g \rangle$, we can apply again (3.32) with $r = N$ and obtain

$$c_g(h, k)^N = 1 \ , \qquad h, k, hk \in C_{M_{24}}(g) \setminus \langle g \rangle \ . \tag{D.28}$$

If α satisfies (D.17) and (D.27), then by (3.32) we have

$$f_{g,N}(g^i) c_g(g^i, h)^N = 1 \ , \qquad \frac{f_{g,N}(g^i) f_{g,N}(g^j)}{f_{g,N}(g^{i+j})} = 1 \ , \tag{D.29}$$

so that

$$f_{g,N}(g^n) = f_{g,N}(g)^n = e^{-\frac{2\pi i n}{\lambda}} \ , \tag{D.30}$$

and

$$c_g(g^i, h)^{N\lambda} = 1 \ . \tag{D.31}$$

Therefore, $c_g(h, k)$ is a $N\lambda$ roots of unity for all $h, k \in C_{M_{24}}(g)$ and we can define $\mu_g(h, k) \in \mathbb{Z}/N\lambda\mathbb{Z}$ such that

$$c_g(h, k) = e^{\frac{2\pi i \mu_g(h,k)}{N\lambda}} \ . \tag{D.32}$$

The discussion is similar to the case $\lambda = 1$. With this choice of cocycle, the central extension $C^{\alpha}_{M_{24}}(g)$ of section 3.2.3 can be chosen to be finite

$$1 \to \langle q(\frac{1}{N\lambda}) \rangle \cong \mathbb{Z}_{N\lambda} \to C^{\alpha}_{M_{24}}(g) \to C_{M_{24}}(g) \to 1 \ . \tag{D.33}$$

It is convenient to define also a central element Q of order N by

$$Q = q(1/N) \ , \tag{D.34}$$

so that the g^r-twisted sector is an eigenspace of Q with eigenvalue $e^{\frac{2\pi i r}{N}}$.

D.3 S-duality for g in classes $2B, 3B, 4C, 6B, 12B$

Here we prove the S-duality transformation property of $\Phi_{g,h}$ for g in the classes 2B, 3B, 4C, 6B, 12B. Let g be an element of M_{24} in one of these classes and let N be its order. In all these cases, the restriction of the class $[\alpha]$ to $H^3(\langle g\rangle, U(1))$ is non-trivial and has order $\lambda = N$. Therefore,

$$\hat{c}_{g,h}(d,m,\ell,t) = \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b m}{N^2}}}{N^2} \operatorname{Tr}_{\mathcal{H}_{g^d}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,d}(g)^{-b}\tilde{\rho}_{g,d}(h)^k(-1)^{F+\bar{F}}\big) . \tag{D.35}$$

In the g^r-twisted sector, for r and N coprime, the spectrum of $L_0 - \frac{c}{24}$ takes values in $-\frac{1}{N^2} + \frac{1}{N}\mathbb{Z}$. More generally, if $\gcd(r,N) = e$, then in the g^r-twisted sector the spectrum of $L_0 - \frac{c}{24}$ takes values in $-\frac{1}{(N/e)^2} + \frac{1}{N/e}\mathbb{Z}$. Notice that $\hat{c}_{g,h}(d,m,\ell,t)$ is a sum of traces in the g^d-twisted sector at level $\frac{md}{N^2}$, so that $\hat{c}_{g,h}(d,m,\ell,t) = 0$ unless $\frac{md}{N^2} \in -\frac{1}{(N/e)^2} + \frac{1}{N/e}\mathbb{Z}$, where $e = \gcd(N,d)$. It is easy to verify that this condition is equivalent to

$$m \equiv -d \mod N , \tag{D.36}$$

where we used the property

$$\gcd(x,N) = 1 \qquad \Leftrightarrow \qquad x^2 \equiv 1 \mod N , \tag{D.37}$$

which holds for all N that divide 24.

As explained in appendix D.2.2, we can choose the cocycle α in such a way that

$$f_{g,N}(h) \equiv \prod_{i=1}^{N-1} c_h(g,g^i) = 1 , \qquad h \in C_{M_{24}}(g) \setminus \langle g\rangle , \tag{D.38}$$

while $f_{g,N}(g^k)$ depends only on the cohomology class $[\alpha]$ and equals

$$f_{g,N}(g^k) = e^{-\frac{2\pi i k}{N}} . \tag{D.39}$$

With this choice of cocycle, we have

$$\tilde{\rho}_{g,x+N}(h) = \frac{\tilde{\rho}_{g,x}(h)}{f_{g,N}(h)} = \tilde{\rho}_{g,x}(h) , \qquad h \in C_{M_{24}}(g) \setminus \langle g\rangle , \tag{D.40}$$

while

$$\tilde{\rho}_{g,x+N}(g) = \frac{\tilde{\rho}_{g,x}(g)}{f_{g,N}(g)} = e^{\frac{2\pi i}{N}}\tilde{\rho}_{g,x}(g) . \tag{D.41}$$

For $d \equiv -m \equiv 0 \mod N$, we have, for all $x \in \mathbb{N}$,

$$\begin{aligned}\hat{c}_{g,h}(d = Nu, m = Nv, \ell, t) &= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b v}{N}}}{N^2} \operatorname{Tr}_{\mathcal{H}_e(uv,\ell)}\big(\tilde{\rho}_{g,Nu}(g)^{-b} \tilde{\rho}_{g,Nu}(h)^k (-1)^{F+\bar{F}}\big) \\ &= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(v-u)}{N}}}{N^2} \operatorname{Tr}_{\mathcal{H}_e(uv,\ell)}\big(g^{-b} h^k (-1)^{F+\bar{F}}\big) \ . \end{aligned} \tag{D.42}$$

Since the (untwisted) twining genera are invariant under charge conjugation, i.e.

$$\phi_{e,g^{-b}h^k}(\tau, z) = \phi_{e,g^b h^{-k}}(\tau, z) \ , \tag{D.43}$$

we obtain

$$\begin{aligned}\hat{c}_{g,h}(Nu, Nv, \ell, t) &= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(v-u)}{N}}}{N^2} \operatorname{Tr}_{\mathcal{H}_e(uv,\ell)}\big(g^b h^{-k} (-1)^{F+\bar{F}}\big) \\ = \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} &\frac{e^{\frac{2\pi i b(u-v)}{N}}}{N^2} \operatorname{Tr}_{\mathcal{H}_e(uv,\ell)}\big(g^{-b} h^{-k} (-1)^{F+\bar{F}}\big) = \hat{c}_{g,h^{-1}}(Nv, Nu, \ell, t) \ . \end{aligned} \tag{D.44}$$

Similarly, for $d \equiv x \equiv -m \mod N$, with $x = 1, \ldots, N-1$, we obtain

$$\begin{aligned}\hat{c}_{g,h}(d = Nu + x, m = Nv + N - x, \ell, t) &= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(Nv+N-x-Nu)}{N^2}}}{N^2} \\ &\quad \times \operatorname{Tr}_{\mathcal{H}_{g^x}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,x}(g)^{-b} \tilde{\rho}_{g,x}(h)^k (-1)^{F+\bar{F}}\big) \ . \end{aligned} \tag{D.45}$$

Using the relation

$$\phi_{g,h}(\tau, z) = \frac{1}{c_h(g, g^{-1}) c_{g^{-1}}(h, h^{-1})} \phi_{g^{-1},h^{-1}}(\tau, z) \ , \tag{D.46}$$

and by

$$\frac{\rho_{g^{-1}}(h^{-1})}{c_{g^{-1}}(h, h^{-1})} = \rho_{g^{-1}}(h)^{-1} \ , \tag{D.47}$$

we obtain

$$\begin{aligned}\operatorname{Tr}_{H_{g^x}(n,\ell)}(\tilde{\rho}_{g,x}(h)) &= \frac{\operatorname{Tr}_{\mathcal{H}_{g^x}(n,\ell)}(\rho_{g^x}(h))}{\prod_{i=1}^{x-1} c_h(g, g^i)} = \frac{\operatorname{Tr}_{\mathcal{H}_{g^{-x}}(n,\ell)}(\rho_{g^{-x}}(h)^{-1})}{c_h(g^x, g^{-x}) \prod_{i=1}^{x-1} c_h(g, g^i)} \\ = \frac{\operatorname{Tr}_{\mathcal{H}_{g^{N-x}}(n,\ell)}(\tilde{\rho}_{g,N-x}(h)^{-1})}{c_h(g^x, g^{N-x}) \prod_{i=1}^{x-1} c_h(g, g^i) \prod_{j=1}^{N-x-1} c_h(g, g^i)} &= \frac{\operatorname{Tr}_{\mathcal{H}_{g^{N-x}}(n,\ell)}(\tilde{\rho}_{g,N-x}(h)^{-1})}{f_{g,N}(h)} \ , \end{aligned} \tag{D.48}$$

where the last equality follows from

$$c_h(g^x, g^{N-x}) \prod_{i=1}^{x-1} c_h(g, g^i) = \prod_{i=N-x}^{N} c_h(g, g^i) \ , \tag{D.49}$$

that in turn is a consequence of the 2-cocycle condition for c_g. It is easy to verify that this identity is compatible with the product in the central extension, i.e.

$$\mathrm{Tr}_{H_{g^x}(n,\ell)}(\tilde{\rho}_{g,x}(h)\tilde{\rho}_{g,x}(k)) = \frac{\mathrm{Tr}_{\mathcal{H}_{g^{N-x}}(n,\ell)}(\tilde{\rho}_{g,N-x}(k)^{-1}\tilde{\rho}_{g,N-x}(h)^{-1})}{f_{g,N}(k) f_{g,N}(h)} \ . \tag{D.50}$$

Using this relation, we obtain

$$\begin{aligned}
&\hat{c}_{g,h}(d = Nu + x, m = Nv + N - x, \ell, t) \\
&= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(Nv-x-Nu)}{N^2}}}{N^2} \mathrm{Tr}_{\mathcal{H}_{g^{N-x}}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,N-x}(g)^b \tilde{\rho}_{g,N-x}(h)^{-k}(-1)^{F+\bar{F}}\big) \\
&= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(Nu+x-Nv)}{N^2}}}{N^2} \mathrm{Tr}_{\mathcal{H}_{g^{N-x}}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,N-x}(g)^{-b} \tilde{\rho}_{g,N-x}(h)^{-k}(-1)^{F+\bar{F}}\big) \\
&= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b(Nu+x)}{N^2}}}{N^2} \mathrm{Tr}_{\mathcal{H}_{g^{N-x}}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,Nv+N-x}(g)^{-b} \tilde{\rho}_{g,Nv+N-x}(h)^{-k}(-1)^{F+\bar{F}}\big) \\
&= \sum_{k=0}^{M-1} \frac{e^{-\frac{2\pi i t k}{M}}}{M} \sum_{b=1}^{N^2} \frac{e^{\frac{2\pi i b d}{N^2}}}{N^2} \mathrm{Tr}_{\mathcal{H}_{g^{m}}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,m}(g)^{-b} \tilde{\rho}_{g,m}(h)^{-k}(-1)^{F+\bar{F}}\big) \ .
\end{aligned} \tag{D.51}$$

Finally, we notice that

$$\tilde{\rho}_{g,r}(h)^{-k} = c_g(h, h^{-1})^{-rk} \tilde{\rho}_{g,r}(h^{-1})^k \ , \tag{D.52}$$

where $c_g(h, h^{-1})$ is a N-th root of unity thanks to our choice of cocycle. We recall that imposing the condition $f_{g,N}(h) = 1$ still leaves the possibility of modifying the cocycle α by a coboundary $\partial\beta$ with $\beta^N = 1$. Under such a modification, $c_g(h, h^{-1})$ transforms as

$$c_g(h, h^{-1}) \to \frac{\beta(g, h)}{\beta(h, g)} \frac{\beta(g, h^{-1})}{\beta(h^{-1}, g)} c_g(h, h^{-1}) \ , \tag{D.53}$$

We distinguish two cases. If h^{-1} and h are not conjugated within $C_{M_{24}}(g)$, then one can choose the cocycle α in such a way that

$$c_g(h, h^{-1}) = 1 \ . \tag{D.54}$$

With this choice, we obtain

$$\hat{c}_{g,h}(d, m, \ell, t) = \hat{c}_{g,h^{-1}}(m, d, \ell, t) \ , \tag{D.55}$$

so that

$$\begin{aligned}\Phi_{g,h}(\sigma,\tau,z) &= pq^{\frac{1}{N^2}}y\prod_{t=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N^2}}y^\ell p^d)^{\hat{c}_{g,h}(d,m,\ell,t)}\\ &= pq^{\frac{1}{N^2}}y\prod_{t=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N^2}}y^\ell p^d)^{\hat{c}_{g,h^{-1}}(m,d,\ell,t)}\\ &= \Phi_{g,h^{-1}}(\frac{\tau}{N^2},N^2\sigma,z)\ .\end{aligned} \tag{D.56}$$

In most cases, however, there is some $w \in C_{M_{24}}(g)$ such that $h^{-1} = w^{-1}hw$. At the level of the central extension $C^{\alpha}_{M_{24}}(g)$, the relation $hw = wh^{-1}$ leads to a relation among the lifts

$$h_\alpha^{-1} = \frac{c_g(w,h^{-1})}{c_g(h,w)c_g(h,h^{-1})}w_\alpha^{-1}h_\alpha w_\alpha = w_\alpha^{-1}Q^n h_\alpha w_\alpha\ , \tag{D.57}$$

where $n \in \mathbb{Z}/N\mathbb{Z}$ is such that

$$e^{-\frac{2\pi in}{N}} = \frac{c_g(h,w)c_g(h,h^{-1})}{c_g(w,h^{-1})}\ , \tag{D.58}$$

and we used the fact that, with our choice of cocycle, the right-hand side is a N-th root of unity. Since $Q^n h_\alpha$ is conjugated with h_α^{-1} within $C^{\alpha}_{M_{24}}(g)$, it must have the same order M, so that $nM \equiv 0 \mod N$ or, equivalently,

$$nM = sN\ , \tag{D.59}$$

for some $s \in \mathbb{Z}/M\mathbb{Z}$. Therefore,

$$\begin{aligned}&\hat{c}_{g,h}(d,m,\ell,t)\\ &\quad= \sum_{k=0}^{M-1}\frac{e^{-\frac{2\pi itk}{M}}}{M}\sum_{b=1}^{N^2}\frac{e^{\frac{2\pi ibd}{N^2}}}{N^2}\,\mathrm{Tr}_{\mathcal{H}_{g^m}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,m}(g)^{-b}\tilde{\rho}_{g,m}(h)^k\tilde{\rho}_{g,m}(Q^n)^k(-1)^{F+\bar{F}}\big)\\ &\quad= \sum_{k=0}^{M-1}\frac{e^{-\frac{2\pi itk}{M}}}{M}\sum_{b=1}^{N^2}\frac{e^{\frac{2\pi ibd}{N^2}}}{N^2}e^{\frac{2\pi inmk}{N}}\,\mathrm{Tr}_{\mathcal{H}_{g^m}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,m}(g)^{-b}\tilde{\rho}_{g,m}(h)^k(-1)^{F+\bar{F}}\big)\\ &\quad= \sum_{k=0}^{M-1}\frac{e^{-\frac{2\pi i(t-sm)k}{M}}}{M}\sum_{b=1}^{N^2}\frac{e^{\frac{2\pi ibd}{N^2}}}{N^2}\,\mathrm{Tr}_{\mathcal{H}_{g^m}(\frac{md}{N^2},\ell)}\big(\tilde{\rho}_{g,m}(g)^{-b}\tilde{\rho}_{g,m}(h)^k(-1)^{F+\bar{F}}\big)\\ &\quad= \hat{c}_{g,h}(m,d,\ell,t-sm)\ .\end{aligned} \tag{D.60}$$

Using this identity, we obtain

$$\begin{aligned}
\Phi_{g,h}(\sigma,\tau,z) &= pq^{\frac{1}{N^2}}y\prod_{t=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N^2}}y^{\ell}p^{d})^{\hat{c}_{g,h}(d,m,\ell,t)} \\
&= pq^{\frac{1}{N^2}}y\prod_{t=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi it}{M}}q^{\frac{m}{N^2}}y^{\ell}p^{d})^{\hat{c}_{g,h}(m,d,\ell,t-sm)} \\
&= pq^{\frac{1}{N^2}}y\prod_{t'=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi ism}{M}}e^{\frac{2\pi it'}{M}}q^{\frac{m}{N^2}}y^{\ell}p^{d})^{\hat{c}_{g,h}(m,d,\ell,t')} \\
&= pq^{\frac{1}{N^2}}y\prod_{t'=1}^{M}\prod_{(d,m,\ell)>0}(1-e^{\frac{2\pi inm}{N}}e^{\frac{2\pi it'}{M}}q^{\frac{m}{N^2}}y^{\ell}p^{d})^{\hat{c}_{g,h}(m,d,\ell,t')} \\
&= e^{-\frac{2\pi in}{N}}\Phi_{g,h}(\frac{\tau}{N^2}+\frac{n}{N},N^2\sigma,z) \\
&= e^{\frac{2\pi in}{N}}\Phi_{g,h}(\frac{\tau}{N^2},N^2\sigma-Nn,z)\ ,
\end{aligned} \tag{D.61}$$

where we used the property that the exponent $\hat{c}_{g,h}(m,d,\ell,t')$ is non-zero only for $d\equiv -m \mod N^2$, so that

$$e^{-\frac{2\pi ix}{N^2}}\Phi_{g,h}(\sigma+\frac{x}{N^2},\tau,z)=e^{\frac{2\pi ix}{N^2}}\Phi_{g,h}(\sigma,\tau-x,z)\ ,\qquad x\in\mathbb{Z}\ . \tag{D.62}$$

The identity (D.61) can be simplified by a suitable choice of the 3-cocycle. Let us shift the cocycle α by a 3-coboundary $\partial\beta$ such that $\frac{\beta(g,h)}{\beta(h,g)}=e^{\frac{2\pi ir}{N^2}}$ for some $r\in\mathbb{Z}$, so that, by (3.56), the new form Φ' satisfies

$$\begin{aligned}
\Phi'_{g,h}(\sigma,\tau,z) &= e^{-\frac{2\pi ir}{N^2}}\Phi_{g,h}(\sigma+\frac{r}{N^2},\tau,z)=e^{\frac{2\pi i(Nn-r)}{N^2}}\Phi_{g,h}(\frac{\tau}{N^2},N^2\sigma+r-Nn,z) \\
&= e^{\frac{2\pi i(r-Nn)}{N^2}}\Phi_{g,h}(\frac{\tau}{N^2}+\frac{Nn-r}{N^2},N^2\sigma,z)=e^{\frac{2\pi i(2r-Nn)}{N^2}}\Phi'_{g,h}(\frac{\tau}{N^2}+\frac{Nn-2r}{N^2},N^2\sigma,z)\ .
\end{aligned} \tag{D.63}$$

By choosing $r=\frac{n(N+N^2)}{2}$, we finally obtain

$$\Phi'_{g,h}(\sigma,\tau,z)=\Phi'_{g,h}(\frac{\tau}{N^2}-n,N^2\sigma,z)=\Phi'_{g,h}(\frac{\tau}{N^2},N^2\sigma,z)\ . \tag{D.64}$$

E Modular forms and Jacobi forms

The Dedekind η function and Jacobi theta functions are defined as

$$\begin{aligned}
\eta(\tau) &= q^{\frac{1}{24}} \prod_{n=1}^{\infty}(1-q^n) \\
\vartheta_1(\tau,z) &= -iq^{\frac{1}{8}}y^{\frac{1}{2}} \prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^{n-1}) \\
\vartheta_2(\tau,z) &= 2\,q^{\frac{1}{8}}\cos(\pi z) \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^n)(1+y^{-1}q^n) \\
\vartheta_3(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^{n-1/2})(1+y^{-1}q^{n-1/2}) \\
\vartheta_4(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1-yq^{n-1/2})(1-y^{-1}q^{n-1/2}) \quad .
\end{aligned} \tag{E.1}$$

The standard weak Jacobi forms $\phi_{0,1}$ and $\phi_{-2,1}$ of index 1 and weight 0 and 2 can be defined as [57]

$$\phi_{0,1}(\tau,z) = 4\sum_{i=2}^{4}\frac{\vartheta_i(\tau,z)^2}{\vartheta_i(\tau,0)^2}\ , \qquad \phi_{-2,1}(\tau,z) = -\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^6}\ . \tag{E.2}$$

Every weak Jacobi forms of weight 0 and index 1 under a congruence subgroup $\Gamma \subseteq SL(2,\mathbb{Z})$ is given by

$$A\phi_{0,1}(\tau,z) + F(\tau)\phi_{-2,1}(\tau,z)\ , \tag{E.3}$$

where A is a constant and $F(\tau)$ is a modular form of weight 2 for Γ.

The Eisenstein series

$$\psi^{(N)} = q\frac{\partial}{\partial q}\log\frac{\eta(N\tau)}{\eta(\tau)} = E_2(\tau) - NE_2(N\tau)\ , \tag{E.4}$$

where

$$E_2(\tau) = -\frac{1}{24} + \sum_{n=1}^{\infty}\Big(\sum_{d|n} d\Big)q^n\ , \tag{E.5}$$

are modular forms of weight 2 under $\Gamma_0(N) \subset SL(2,\mathbb{Z})$. We will also need the newforms

$$f_{23,a}(\tau) = q - q^3 - q^4 - 2q^6 + 2q^7 - q^8 + 2q^9 + 2q^{10} + \cdots \tag{E.6}$$

$$f_{23,b}(\tau) = -q^2 + 2q^3 + q^4 - 2q^5 - q^6 - 2q^7 + 2q^8 + 2q^{10} + \cdots \tag{E.7}$$

that are modular (cusp) forms of weight 2 for $\Gamma_0(23)$.

F Tables

In the following tables, we collect information about the 55 abelian subgroups $\langle g, h\rangle$ of M_{24} and the corresponding twisted twining genera.

Table 1 describes the 21 cyclic subgroups $\langle g\rangle$, $g \in M_{24}$ and the corresponding twining genera. For each group we report the conjugacy class of the generators, the orbits in the 24-dim representation, the twisted twining genera for some pairs of elements in the group. The twining genus $\phi_{e,g}$ is a weak Jacobi form of weight 0 and index 1 for the group

$$\Gamma_0(N) := \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid c \equiv 0 \mod N\} , \tag{F.1}$$

where N is the order of the g. Thus, $\phi_{e,g}$ is given by $\frac{\mathrm{Tr}_{\mathbf{24}}(g)}{12}\phi_{0,1}(\tau,z) + F_{e,g}(\tau)\phi_{-2,1}(\tau,z)$, where $\phi_{0,1}(\tau,z)$, $\phi_{-2,1}(\tau,z)$ are the standard generators of the ring of weak Jacobi forms of index 1 and $\mathrm{Tr}_{\mathbf{24}}(g)$ and $F_{e,g}(\tau)$ are reported in the last two columns. The table is divided into two parts, the first containing the groups whose generators are in some M_{23} subgroup of M_{24} (equivalently, the groups have some fixed points in the 24-dimensional permutation representation).

Table 2 contains information about the 34 conjugacy classes of non-cyclic abelian groups of M_{24} (see [17]). For each such $\langle g, h\rangle \subset M_{24}$ we have described the structure as an abelian group, i.e. as $\mathbb{Z}_m \times \mathbb{Z}_n$, the M_{24} classes of all its elements (excluding the identity), the order of the centralizer $C(g,h)$ and its index $|N(g,h)|/|C(g,h)|$ in the normalizer of $\langle g, h\rangle$ in M_{24}, and the lengths of the orbits of $\langle g, h\rangle \subset M_{24}$ when acting as a group of permutations of 24 objects. Furthermore, we give a classification of all modular groups $\Gamma_{g,h} \subset PSL(2,\mathbb{Z})$ and twisted twining genera $\phi_{g,h}$ for commuting pairs $g, h \in M_{24}$. The latter functions are denoted as $\phi_{[g],[h]}$, where the first subscript is the M_{24}-class of g and the second is $C_{M_{24}}(g)$-class of h; the names of the classes follow the conventions of [17]. Finally, for each of the 34 groups we provide the explicit expressions of the twisted twining genera $\phi_{g,h}$ and $\mathcal{T}_L^{\alpha}\phi_{g,h}$, $L = 2, 3, 4$, for a pair (g,h) of generators and for a choice of cocycle α satisfying (D.17) and (D.21) (when g is in $M_{23} \subset M_{24}$) or (D.27) (otherwise).

Group 27 is the only case where the pairs (g,h) and (g^{-1},h^{-1}) are not conjugated within M_{24}. Thus, in this case, charge conjugation gives the identities $\phi_{\mathrm{2B},\mathrm{8A}_1} = \phi_{\mathrm{2B},\mathrm{8A}_2}$, $\phi_{\mathrm{8A},\mathrm{2B}_1} = \phi_{\mathrm{8A},\mathrm{2B}_2}$, and so on, and the respective functions are denoted in the following tables by $\phi_{\mathrm{2B},\mathrm{8A}_{1,2}}$, $\phi_{\mathrm{8A},\mathrm{2B}_{1,2}}$, etcetera.

Most of the modular groups $\Gamma_{g,h}$ are of the form $\Gamma(1) = SL(2,\mathbb{Z})$, $\Gamma_0(N)$ or conjugates of $\Gamma_0(N)$ in $SL(2,\mathbb{Z})$. The exceptions are the group in case 32, where

$$\Gamma_{\mathrm{2B},\mathrm{10A}} = \bigcup_{i\in\mathbb{Z}/3\mathbb{Z}, j\in\mathbb{Z}/4\mathbb{Z}} \left(\begin{smallmatrix} 1 & 1 \\ -5 & -4 \end{smallmatrix}\right)^i \left(\begin{smallmatrix} -3 & -1 \\ 10 & 3 \end{smallmatrix}\right)^j \Gamma_{2,10} , \tag{F.2}$$

is a subgroup of index 12 in $SL(2,\mathbb{Z})$ and

$$\Gamma_{2,10} := \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid a \equiv 1,\ b \equiv 0 \mod 2,\ c \equiv 0,\ d \equiv 1 \mod 10\}\ , \tag{F.3}$$

is the group of elements $\gamma \in SL(2,\mathbb{Z})$ such that $(g,h)\cdot\gamma = (g,h)$; the group in case 12, with

$$\Gamma_{\mathrm{2A,4A}} = \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid b \equiv 0 \mod 2, c \equiv 0 \mod 4\}\ , \tag{F.4}$$

which is a conjugate of $\Gamma_0(8)$ in $SL(2,\mathbb{R})$; and the group in case 22, with

$$\Gamma_{\mathrm{4A,4C}} = \langle \left(\begin{smallmatrix} -1 & 1 \\ -2 & 1 \end{smallmatrix}\right)\ ,\ \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)\ ,\ \left(\begin{smallmatrix} 1 & 0 \\ 4 & 1 \end{smallmatrix}\right)\ ,\ \left(\begin{smallmatrix} 3 & -2 \\ -4 & 3 \end{smallmatrix}\right) \rangle\ . \tag{F.5}$$

Table 3: The eta products of [33]. For each pair g,h, a cycle shape of the form $\prod_\ell \ell^{i(\ell)}$ is given: the corresponding eta-product is $\eta_{g,h}(\tau)=\prod_\ell \eta(\ell\tau/N\lambda)^{i(\ell)}$, where N is the order of g and λ is the length of the shortest cycle. In the last column, w is the modular weight.

Table 4: Relabeling for g in class 2A. Each line corresponds to a conjugacy class in the central extension $C^{\alpha}_{M_{24}}(g)$. For each such class, we report the corresponding class in $C_{M_{24}}(g)$ with representative h, the group $\langle g,h\rangle$ generated by g and h, the 'relabeled' class in $C_{M_{24}}(g)$ with representative h' and the group $\langle g,h'\rangle$ generated by g and h'.

GENERALISED MATHIEU MOONSHINE

MATTHIAS R. GABERDIEL, DANIEL PERSSON, HENRIK RONELLENFITSCH,
AND ROBERTO VOLPATO

Abstract. The Mathieu twisted twining genera, i.e. the analogues of Norton's generalised Moonshine functions, are constructed for the elliptic genus of K3. It is shown that they satisfy the expected consistency conditions, and that their behaviour under modular transformations is controlled by a 3-cocycle in $H^3(M_{24}, U(1))$, just as for the case of holomorphic orbifolds. This suggests that a holomorphic VOA may be underlying Mathieu Moonshine.

1. INTRODUCTION

1.1. **Monstrous Moonshine.** In mathematics and physics the word ‘Moonshine’ has come to represent various surprising and deep connections between a priori unrelated fields, such as number theory, representation theory of finite groups, algebra and quantum field theory. The first and most well-known example of such a connection is, of course, Conway and Norton’s *Monstrous Moonshine conjecture* [1]. Their starting point was the observation of McKay that the first few Fourier coefficients of the modular invariant J-function $J(\tau)$ are dimensions of representations of the Monster group $\mathbb{M}$, the largest finite simple sporadic group. Conway and Norton then conjectured that to each element $g \in \mathbb{M}$ of the Monster, one can associate a function $T_g(\tau)$ (the so-called McKay-Thompson series) on the upper half-plane $\mathbb{H}_+$ that is invariant under some subgroup $\Gamma_g \subset SL(2,\mathbb{R})$. They also conjectured that the invariance group Γ_g must be genus zero, meaning that, as a Riemann surface, the quotient $\Gamma_g \backslash \mathbb{H}_+$ is topologically a sphere. Furthermore, they conjectured that $T_g(\tau)$ is in fact the Hauptmodul for Γ_g.

Subsequently, Frenkel, Lepowsky and Meurman (FLM) [2] constructed a graded $\mathbb{M}$-module $V^\natural = \bigoplus_{n=-1}^{\infty} V_n^\natural$, such that the dimension of the graded subspaces $a(n) = \dim V_n^\natural$ reproduce precisely the Fourier coefficients in the q-expansion of the J-function, $J(\tau) = \sum_{n=-1}^{\infty} a(n)q^n$, $q = e^{2\pi i\tau}$. The coefficients $a_g(n)$ in the Fourier expansion of the McKay-Thompson series are then identified with the characters $\mathrm{Tr}_{V_n^\natural}(g)$. Physically, the FLM-module is the $\mathbb{Z}_2$-orbifold of the open bosonic string compactified on the Leech torus $(\mathbb{R}^{24}/\Lambda_{\text{Leech}})$, where Λ_{Leech} is the Leech lattice. The FLM-construction provided important clues into the moonshine conjectures, but fell short of proving them. The final proof was found by Borcherds [3], making heavy use of the FLM-module $V^\natural$, but also introducing yet another set of ingredients to the story, namely generalised Kac-Moody algebras and automorphic denominator identities. Thus, by the time the original conjectures were proven, Monstrous Moonshine encompassed not only the realms of finite groups and modular forms, but also string theory and infinite-dimensional algebras, for a nice review see [4].

1.2. **Mathieu Moonshine.**

Recently, a very interesting new moonshine phenomenon was conjectured by Eguchi, Ooguri and Tachikawa (EOT) [5]: they observed that the first few Fourier coefficients of the elliptic genus of K3 are dimensions of representations of the largest Mathieu group M_{24}. This suggests the existence of a new moonshine-type connection between Mathieu groups, Jacobi forms and K3 surfaces. The analogues of the McKay-Thompson series, the *twining elliptic genera* $\phi_g(\tau, z)$, $g \in M_{24}$, were constructed in a series of papers [6, 7, 8, 9], and it was shown that they are all weak Jacobi forms of weight 0 and index 1 (with multiplier system) for subgroups $\Gamma_0(N_g) \subset SL(2, \mathbb{Z})$, where N_g is the order of the element g. (The elliptic genus ϕ_{K3} itself corresponds to taking g to be the identity element.) The compatibility with M_{24}-representations was checked up to the first 600 coefficients [8, 9]; according to Gannon [10] this is sufficient to prove that all Fourier coefficients of the elliptic genus of K3 are dimensions of M_{24} representations. It is also shown in [10] that the multiplicities of the real M_{24} representations are always even, see also [11].

Although in a certain sense the above results establish the Mathieu Moonshine conjecture, there are many aspects of it that are much less understood compared to Monstrous Moonshine. For instance, the genus zero property of Monstrous Moonshine does not seem to hold for the M_{24}-twining genera since some of the invariance groups $\Gamma_0(N_g)$ are not genus zero.[*] More importantly, the analogue of the FLM module $V^\natural$ is not yet known for Mathieu Moonshine, i.e. we do not know of any CFT with automorphism group M_{24} whose elliptic genus reproduces the elliptic genus of K3. In particular, none of the K3-sigma models have this property since M_{24} is not contained in the automorphism group of any of them [13].

---

[*] It was proposed in [12] that the correct generalisation of the genus zero property is a certain Rademacher-summability condition, which is indeed satisfied in all cases.

1.3. **Generalised Monstrous Moonshine.** A few years after the original Monstrous Moonshine conjectures, Norton proposed a generalisation that he dubbed *Generalised Moonshine* [14]. He suggested that for each commuting pair of Monster group elements $g, h \in \mathbb{M}$ there exists a function $f(g, h; \tau)$ that is also invariant under a genus zero subgroup of $SL(2, \mathbb{R})$. These functions generalise the McKay-Thompson series to which they reduce for $g = e$. Furthermore, they transform into one another under a simultaneous action of $SL(2, \mathbb{Z})$ on $(\tau; g, h) \in \mathbb{H}_+ \times \mathcal{P}(\mathbb{M})$, where $\mathcal{P}(\mathbb{M}) \subset \mathbb{M} \times \mathbb{M}$ is the set of pairs of commuting elements of $\mathbb{M}$. Finally, the Fourier coefficients in the q-expansion of $f(g, h; \tau)$ are conjectured to be dimensions of (projective) representations of the centraliser of g in $\mathbb{M}$, $C_{\mathbb{M}}(g) = \{k \in \mathbb{M} : gk = kg\}$. Although this conjecture has been proven in special cases [15, 16, 17], the general case is still open.[†]

The Generalised Moonshine conjecture was given a physical interpretation by Dixon, Ginsparg and Harvey [24] that was later elaborated upon by Ivanov and Tuite [17, 18, 19]. They showed that the Norton series $f(g, h; \tau)$ arises naturally as the character in the twisted sector $V^\natural_g$ of an orbifold of the Monster CFT $V^\natural$ by the element $g \in \mathbb{M}$, 'twined' by the group element h; in standard CFT language, they can therefore be interpreted as

$$f(g,h;\tau) = g\, \underset{h}{\boxed{}} = \mathrm{Tr}_{V^\natural_g}\left(h\, q^{L_0-1}\right) \ . \tag{1}$$

Many of the properties conjectured by Norton can be proved from holomorphic orbifold considerations [15].

1.4. **Generalised Mathieu Moonshine.** In this paper, we show that Norton's generalisation also applies to Mathieu Moonshine. More specifically, for every pair of commuting group elements $g, h \in M_{24}$, we construct 'twisted twining genera' $\phi_{g,h} : \mathbb{H}_+ \times \mathbb{C} \to \mathbb{C}$ that either vanish or are weak Jacobi forms of weight 0 and index 1 for some $\Gamma_{g,h} \subset SL(2, \mathbb{Z})$. For $g = e$, they reduce to the twining genera of [6, 7, 8, 9], and they transform under the modular group $SL(2, \mathbb{Z})$ into one another. The multiplier phases that appear in these transformations behave as though these twisted twining genera were twisted twining characters of a holomorphic orbifold; in particular, they are controlled by a 3-cocycle $\alpha \in H^3(M_{24}, U(1))$ via a formula that was first written down by Dijkgraaf and Witten in [25]. Furthermore, the Fourier coefficients of the twisted elliptic genera $f(g, e; \tau)$ equal dimensions of projective representations of the centraliser $C_{M_{24}}(g)$, and the central extension that characterises the projective representation is again determined by the cohomology class $\alpha \in H^3(M_{24}, U(1))$.

[†] Carnahan has announced a series of papers [20, 21, 22, 23] which he claims will lead to a complete proof.

The idea for using the cohomology group $H^3(M_{24}, U(1))$ and the formalism of Dijkgraaf and Witten in order to understand the multiplier phases of the twisted twining genera was first suggested to us by Terry Gannon in 2011 [26], see also [10]. Mason has also speculated [27] that $H^3(\mathbb{M}, U(1))$ should play a similar role in the context of Generalised Monstrous Moonshine, although this has, to our knowledge, not yet been worked out (partially, because $H^3(\mathbb{M}, U(1))$ is unknown).

We should also mention that Mason has previously proposed a version of Generalised Moonshine for M_{24} [28], where the role of the Norton series $f(g, h; \tau)$ is played by products of eta functions $\eta(\tau)$. The precise relation between our twisted twining genera and Mason's eta products will be explained elsewhere [29].

1.5. **Outline.** The paper is organised as follows. In section 2 we introduce the twisted twining genera $\phi_{g,h}$, and discuss their general properties, in particular the expected behaviour under modular transformations. Based on these properties we then explain how many independent twisted twining genera there are, and list all of them explicitly, see table 3. The detailed derivation of these genera is illustrated in section 3. First, we review the structure of holomorphic orbifolds and explain in particular, the role of the 3-cocycle in characterising the various transformation properties of the twisted twining characters. We then postulate that the transformation properties of the twisted twining genera are similarly constrained. In support of this assumption, we prove that there exists a unique 3-cocycle in $H^3(M_{24}, U(1))$ compatible with the known properties of the (untwisted) twining genera of [6, 7, 8, 9]. This then allows us to find all twisted twining genera explicitly. We also check that, up to the first 500 levels in each twisted sector, the resulting functions are compatible with the requirement that they arise from the appropriate projective representation of the centraliser. In section 4 we subject our results to two independent consistency checks. First, for group elements whose orbifold leads again to a K3 sigma-model, we calculate the twining genera of the orbifold from the twisted twining genera of the original theory, and show that we reproduce answers from [8, 9]. However, as it turns out, the relevant group element is sometimes different from what one would have expected, and we explain this 'relabelling' phenomenon in quite some detail in section 4.1, see also section 4.2 for an explicit example. Secondly, we explain the vanishing of some of the twisted twining genera from a geometrical point of view, see section 4.3. Finally we end with some conclusions and open problems in section 5. We have relegated some of the more technical material to various appendices to which we refer throughout the main body of the paper. Moreover, the appendices contain the character tables of the centralisers and the decompositions of the twisted sectors, up to the first 20 levels. The decompositions up to 500 levels, as well as the details of the computations requiring computer support, are collected in the ancillary files in the arXiv repository of this paper.

2. Twisted Twining Genera

Let us begin by introducing the twisted twining genera that are the main object of this paper. Suppose we are given a K3 sigma-model $\mathcal{H}$, i.e. a CFT describing string propagation on K3, whose automorphism group contains two commuting elements $g, h \in M_{24}$. Then we can consider the orbifold of the sigma-model by g, and in particular, define the g-twisted sector $\mathcal{H}_g$. Since g and h commute, h gives rise to an action on $\mathcal{H}_g$, and we can define the *twisted twining genus* $\phi_{g,h}(\tau, z)$ by

$$\phi_{g,h}(\tau,z) = \operatorname{Tr}_{\mathcal{H}_g}\Big(h(-1)^{J_0+\bar{J}_0} q^{L_0-\frac{c}{24}} \bar{q}^{\bar{L}_0-\frac{\bar{c}}{24}} y^{J_0}\Big)\ , \tag{2}$$

where $q = e^{2\pi i\tau}$ and $y = e^{2\pi i z}$. We expect that $\phi_{g,h} : \mathbb{H}_+ \times \mathbb{C} \to \mathbb{C}$ is holomorphic in both τ and z. Furthermore, since the elliptic genus is independent of the choice of the underlying K3 sigma-model, we expect that the same is true for these twisted twining genera, i.e. we expect that (2) does not depend on the choice of $\mathcal{H}$ (as long as g and h are automorphisms of $\mathcal{H}$). By construction, for $g = e$ the identity element in M_{24}, the twisted twining genus $\phi_{e,h}$ agrees with the twining genus ϕ_h considered in [6, 7, 8, 9]; in particular, for $g = h = e$ $\phi_{e,e}$ is just the elliptic genus of K3.

Unfortunately, while for some commuting pairs (g, h) an actual K3 sigma-model for which both g and h are automorphisms can be found, this is not true in general [13]; in fact, this problem already arises for the usual twining genera, i.e. for the pairs (e, h). In the spirit of the EOT conjecture, we shall nevertheless assume that twisted twining genera $\phi_{g,h}$ can be defined — albeit not directly by a formula of the form (2) — for *all* commuting pairs $g, h \in M_{24}$. The fact that our construction will be successful is an a posteriori justification for this assumption.

2.1. **Properties of the twisted twining genera.** The definition of the twisted twining genera $\phi_{g,h}$ in terms of (2) suggests that they should satisfy the following properties:

(A) Elliptic and modular properties:

$$\phi_{g,h}(\tau, z+\ell\tau+\ell') = e^{-2\pi i(\ell^2\tau+2\ell z)}\,\phi_{g,h}(\tau,z) \qquad \ell,\ell'\in\mathbb{Z} \tag{3}$$

$$\phi_{g,h}\Big(\frac{a\tau+b}{c\tau+d},\frac{z}{c\tau+d}\Big) = \chi_{g,h}\big(\begin{smallmatrix} a & b\\ c & d\end{smallmatrix}\big)\, e^{2\pi i\frac{cz^2}{c\tau+d}}\,\phi_{h^cg^a,h^dg^b}(\tau,z)\ , \quad \big(\begin{smallmatrix} a & b\\ c & d\end{smallmatrix}\big)\in SL(2,\mathbb{Z}) \tag{4}$$

for a certain multiplier $\chi_{g,h} : SL(2,\mathbb{Z}) \to U(1)$. In particular, each $\phi_{g,h}$ is a weak Jacobi form of weight 0 and index 1 with multiplier $\chi_{g,h}$ under a subgroup $\Gamma_{g,h}$ of $SL(2,\mathbb{Z})$ (see [30] for the definitions).

(B) Invariance under conjugation of the pair g, h in M_{24},

$$\phi_{g,h}(\tau,z) = \xi_{g,h}(k)\,\phi_{k^{-1}gk,k^{-1}hk}(\tau,z)\ , \qquad k\in M_{24}\ , \tag{5}$$

where $\xi_{g,h}(k)$ is a phase.

(C) If $g\in M_{24}$ has order N, the twisted twining genera $\phi_{g,h}$ have an expansion of the form

$$\phi_{g,h}(\tau,z) = \sum_{\substack{r\in\lambda_g+\mathbb{Z}/N\\ r\geq 0}} \mathrm{Tr}_{\,\mathcal{H}_{g,r}}\big(\rho_{g,r}(h)\big)\,\mathrm{ch}_{h=\frac{1}{4}+r,\ell}(\tau,z)\ , \tag{6}$$

where $\lambda_g\in\mathbb{Q}$, and $\mathrm{ch}_{h,\ell}(\tau,z)$ are elliptic genera of Ramond representations of the $\mathcal{N}=4$ superconformal algebra at central charge $c=6$. (Here $\ell=\frac{1}{2}$, except possibly for $h=\frac{1}{4}$, where $\ell=0$ is also possible — if both $\ell=0,\frac{1}{2}$ appear for $r=0$, it is understood that there are two such terms in the above sum. We use the same conventions for the elliptic genera as e.g. in [31].) Furthermore, each vector space $\mathcal{H}_{g,r}$ is finite dimensional, and it carries a projective representation $\rho_{g,r}$ of the centraliser $C_{M_{24}}(g)$ of g in M_{24}, such that

$$\rho_{g,r}(g) = e^{2\pi i r}\ , \qquad \rho_{g,r}(h_1)\,\rho_{g,r}(h_2) = c_g(h_1,h_2)\,\rho_{g,r}(h_1h_2)\ , \tag{7}$$

for all $h_1,h_2\in C_{M_{24}}(g)$. Here $c_g : C_{M_{24}}(g)\times C_{M_{24}}(g)\to U(1)$ is independent of r, and satisfies the cocycle condition

$$c_g(h_1,h_2)\,c_g(h_1h_2,h_3) = c_g(h_1,h_2h_3)\,c_g(h_2,h_3) \tag{8}$$

for all $h_1,h_2,h_3\in C_{M_{24}}(g)$.

(D) For $g=e$, where e is the identity element of M_{24}, the functions $\phi_{e,h}$ correspond to the twining genera considered in [6]–[9]. In particular, $\phi_{e,e}$ is the K3 elliptic genus.

Since the elliptic genus behaves essentially like the character of a holomorphic CFT — in particular, it is modular invariant and holomorphic by itself — it is natural to believe that the same will be true for the twisted twining genera, i.e. that they will be analogous to twisted twining characters of a holomorphic CFT. As we will review in more detail in section 3, the modular properties of the twisted twining characters of a holomorphic CFT are controlled by a 3-cocycle $\alpha : G \times G \times G \to U(1)$ representing a cohomology class in the third cohomology group $H^3(G, U(1))$. (Some background material about group cohomology can be found in appendix B.) We will therefore postulate that

(E) The multipliers $\chi_{g,h}$, the phases $\xi_{g,h}$, and the 2-cocycles c_g associated with the projective representations $\rho_{g,r}$ are completely determined (by the same formulas as for holomorphic orbifolds) in terms of a 3-cocycle α representing a class in $H^3(M_{24}, U(1))$.

The third cohomology group of M_{24} was only recently computed with the result [32][‡]

$$H^3(M_{24}, U(1)) \cong \mathbb{Z}_{12} \ . \tag{9}$$

The fact that this group is known explicitly plays a crucial role in our analysis. The specific cohomology class $[\alpha] \in H^3(M_{24}, U(1))$ that is relevant in our context is uniquely determined by the condition that it reproduces the multiplier system for the twining genera $\phi_{e,h}$ as described in [8], namely

$$\chi_{e,h}\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) = e^{\frac{2\pi i cd}{o(h)\ell(h)}} \ , \qquad \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(o(h)) \ . \tag{10}$$

Here, $o(h)$ is the order of h and $\ell(h)$ is the length of the smallest cycle, when $h \in M_{24}$ is regarded as a permutation of 24 symbols [12]. Indeed, since $\ell(12\mathrm{B}) = 12$, it follows that α must correspond to the primitive generator of $H^3(M_{24}, U(1))$. The main result of our paper can now be stated as follows:

There exists a unique set of functions $\phi_{g,h}$ (unique up to redefinitions by (g,h)-dependent but otherwise constant phases) and a unique cohomology class $[\alpha] \in H^3(M_{24}, U(1))$ such that all conditions (A)–(E) are satisfied (condition (C) has been verified only for the first 500 representations $\rho_{g,r}$ for each $g \in M_{24}$).

When $g = e$ is the trivial element of M_{24}, the existence of all representations $\rho_{e,r}$ fitting eq. (6) has been recently proven in [10]. When $g \neq e$, condition (C) is, strictly speaking, still a conjecture. However, we provide compelling numerical evidence in favour of it, by

---

[‡] Note that for a finite group G one has the isomorphisms

$$H_{n-1}(G, \mathbb{Z}) \cong H^n(G, \mathbb{Z}), \qquad H^n(G, \mathbb{Z}) \cong H^{n-1}(G, U(1)) \ ,$$

which in particular imply that $H_3(M_{24}, \mathbb{Z}) \cong H^3(M_{24}, U(1))$.

verifying eq. (6) for the first 500 representations $\rho_{g,r}$ in each twisted sector. A complete proof of (6) should be possible along the lines of [10].

In the following we want to illustrate how the set of functions $\phi_{g,h}$ can be determined, and which explicit form it takes. As it turns out, a surprisingly large number of the twisted twining genera vanish, as we shall now explain.

2.2. **Cohomological obstructions.** For some pairs of commuting elements $g, h \in M_{24}$, the transformation properties above can only be satisfied if $\phi_{g,h}$ vanishes identically. In this case, we will say that the corresponding twisted twining genus is *obstructed*. As will be shown in more detail in section 3, these obstructions are also controlled by the cohomology class of the cocycle $\alpha \in H^3(M_{24}, U(1))$.[§]

In order to understand the origin of these obstructions, let us first derive some general consequences of our assumptions (A)–(E). First we note that the $SL(2,\mathbb{Z})$ action on the twisted twining characters can be extended to $GL(2,\mathbb{Z})$ by setting

$$\phi^*_{g,h}(\tau,z) = \chi_{g,h}\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)\, \phi_{g,h^{-1}}(\tau,z) \ , \tag{11}$$

where $\phi^*_{g,h}(\tau,z)$ is obtained by taking the complex conjugate of all Fourier coefficients of $\phi_{g,h}(\tau,z)$

$$\phi^*_{g,h}(\tau,z) = \overline{\phi_{g,h}(-\bar\tau,-\bar z)} \ . \tag{12}$$

The identity (11) follows from eq. (6), together with the observation that, for any projective representation R of a finite group G, $\mathrm{Tr}_R(h^{-1})$ equals $\overline{\mathrm{Tr}_R(h)}$ up to a phase, which we have denoted by $\chi_{g,h}\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. As we will see, this phase also depends on the 3-cocycle α. We also note that since the $\mathcal{N}=4$ characters are invariant under $z \to -z$, we have the identity

$$\phi_{g,h}(\tau,-z) = \phi_{g,h}(\tau,z) \ . \tag{13}$$

With these preparations we can now describe two possible kinds of obstructions.

Obstruction 1: Let us consider pairwise commuting g, h, k. Then, by (5), we have

$$\phi_{g,h}(\tau,z) = \xi_{g,h}(k)\, \phi_{g,h}(\tau,z) \ , \tag{14}$$

and if

$$\xi_{g,h}(k) \neq 1 \ , \tag{15}$$

it follows that $\phi_{g,h}(\tau,z) = 0$.

[§] The fact that such obstructions might exist was first suggested to us by T. Gannon.

Obstruction 2: Suppose there are $g, h, k \in M_{24}$, with g and h commuting and

$$k^{-1}g^{-1}k = g \ , \qquad k^{-1}h^{-1}k = h \ , \tag{16}$$

i.e. the commuting pair (g, h) is conjugate within M_{24} to the pair (g^{-1}, h^{-1}). Then, by eqs. (51) and (42) (see section 3 for details), we obtain the relations

$$\phi_{g,h}(\tau, z) = \chi_{g,h}\left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix} \right) \phi_{g^{-1},h^{-1}}(\tau, -z) \tag{17}$$

$$= \chi_{g,h}\left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix} \right) \xi_{g^{-1},h^{-1}}(k)\, \phi_{g,h}(\tau, -z) \ . \tag{18}$$

Therefore, if

$$\chi_{g,h}\left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix} \right) \xi_{g^{-1},h^{-1}}(k) \neq 1 \ , \tag{19}$$

eq. (13) implies $\phi_{g,h}(\tau, z) = 0$.
As we shall see, these two obstructions are responsible for the fact that most twisted twining genera vanish.

2.3. Classification of independent twisted twining genera.

Our next aim is to enumerate all possible independent twisted twining genera. Let us denote the set of commuting group elements by

$$\mathcal{P} = \{(g, h) \in M_{24} \times M_{24} \mid gh = hg\} \ . \tag{20}$$

This set carries an action of $GL(2, \mathbb{Z}) \times M_{24}$, given by

$$(g, h) \mapsto (k^{-1}(g^a h^c)k, k^{-1}(g^b h^d)k) \ , \quad \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \in GL(2, \mathbb{Z}) \ , \quad k \in M_{24} \ , \tag{21}$$

and the twisted twining genera associated to different (g, h)'s in the same orbit are related to one another by modular transformations, see eqs. (4), (5), and/or by complex conjugation, see eq. (11). We therefore want to describe the set of orbits of $\mathcal{P}$ under the action (21).

First we note that the $GL(2, \mathbb{Z})$ orbit of a pair (g, h) consists of all possible pairs of generators of the abelian group $\langle g, h \rangle \subset M_{24}$. Thus the orbits of $GL(2, \mathbb{Z}) \times M_{24}$ are in one-to-one correspondence with the conjugacy classes of abelian subgroups of M_{24} generated by two elements, i.e.

$$\bar{\mathcal{P}} = \mathcal{P}/(GL(2, \mathbb{Z}) \times M_{24}) = \{M_{24} - \text{conjugacy classes of groups } \langle g, h \rangle \subset M_{24}, gh = hg\} \ . \tag{22}$$

This description allows a complete classification of the orbits $[g, h] \in \bar{\mathcal{P}}$: there are 55 such orbits, 21 of which correspond to cyclic subgroups, i.e. to subgroups of the form $[e, h]$. The associated twisted twining genera are therefore just the twining genera $\phi_{e,h}$, for which explicit expressions were already derived in [8, 9]. Thus we only need to construct

#	Structure	Elements	$\lvert C(g,h)\rvert$	$\frac{\lvert N(g,h)\rvert}{\lvert C(g,h)\rvert}$	Orbits on **24**	Max subgr.

TABLE 1. The 34 conjugacy classes of abelian subgroups of rank 2 in M_{24}.

the remaining 34 genuinely twisted twining genera. We have tabulated the corresponding conjugacy classes of groups $\langle g,h\rangle$ in table 1. There we have described their structure as an abelian group, i.e. as $\mathbb{Z}_m \times \mathbb{Z}_n$, the M_{24} classes of all its elements (excluding the identity), the order of the centraliser $C(g,h)$, the index $|N(g,h)|/|C(g,h)|$ of the centraliser in the normaliser of $\langle g,h\rangle$ in M_{24}, and the lengths of the orbits of $\langle g,h\rangle \subset M_{24}$ when acting as a group of permutations of 24 objects. Finally, the last column gives the conjugacy classes of the non-cyclic maximal subgroups. For example, group 24 has three distinct non-cyclic maximal subgroups, all of the form $\mathbb{Z}_2 \times \mathbb{Z}_4$; two of them are conjugated to group 11 and one is conjugated to group 18.

For M_{24} it turns out that the orbits of $\mathcal{P}$ under $SL(2,\mathbb{Z}) \times M_{24}$ are exactly the same as those under $GL(2,\mathbb{Z}) \times M_{24}$, i.e.[¶]

$$\bar{\mathcal{P}} = \mathcal{P}/(GL(2,\mathbb{Z}) \times M_{24}) = \mathcal{P}/(SL(2,\mathbb{Z}) \times M_{24}) \ . \tag{23}$$

Thus the twisted twining genera in each orbit in $\bar{\mathcal{P}}$ are just related by phases, see eqs. (4) and (5), and we do not need to invoke eq. (11).

2.4. **Modular properties of the twisted twining genera.** For each commuting pair $(g,h) \in \mathcal{P}$, let us denote by $\tilde{\Gamma}_{g,h} \subset SL(2,\mathbb{Z}) \times M_{24}$ the group of elements (γ, k) that leave the pair (g,h) fixed or map it to its inverse (g^{-1},h^{-1})

$$\tilde{\Gamma}_{g,h} = \left\{ \left(\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right), k \right) \in SL(2,\mathbb{Z}) \times M_{24} \mid \left(k^{-1}(g^a h^c)k,\, k^{-1}(g^b h^d)k \right) = (g,h) \text{ or } (g^{-1},h^{-1}) \right\} \ . \tag{24}$$

It follows from (4) and (5), together with (13) as well as (51) below, that the corresponding twisted twining genus $\phi_{g,h}$ will be invariant (up to a phase) under $\Gamma_{g,h} \equiv \pi(\tilde{\Gamma}_{g,h})$, where π denotes the projection of $SL(2,\mathbb{Z}) \times M_{24}$ onto its first factor, i.e. onto $SL(2,\mathbb{Z})$.

Each twisted twining genus $\phi_{g,h}$ belongs to a (finite-dimensional) vector representation of $SL(2,\mathbb{Z})$, that is spanned by the functions $\{\phi_{(g,h)\gamma}(\tau,z)\}$, where $\gamma \in SL(2,\mathbb{Z})$. Since every $\gamma \in \Gamma_{g,h}$ acts trivially (i.e. up to a phase) on $\phi_{g,h}$, the $SL(2,\mathbb{Z})$ representation is spanned by $\{\phi_{(g,h)\gamma}(\tau,z)\}_{\gamma \in \Gamma_{g,h}\backslash SL(2,\mathbb{Z})}$, where γ runs over a set of representatives for the cosets in $\Gamma_{g,h}\backslash SL(2,\mathbb{Z})$. Each of these functions $\phi_{(g,h)\gamma}$ is a weak Jacobi form of weight 0 and index 1 for the congruence subgroup $\gamma^{-1}\Gamma_{g,h}\gamma \subseteq SL(2,\mathbb{Z})$. We have tabulated for each orbit $[g,h] \in \bar{\mathcal{P}}$ the functions $\phi_{(g,h)\gamma}$ (starting from $\phi_{g,h}$) and the invariance group $\Gamma_{g,h}$ in table 2. (Note, however, that some of these functions vanish identically; in particular, this will be the case if there is an obstruction.) Each $\phi_{g,h}$ is denoted by the M_{24} class of g and the $C_{M_{24}}(g)$-class of h, named as in appendix D.

[¶] For a generic group G different from M_{24}, some $SL(2,\mathbb{Z}) \times G$ orbits might be strictly smaller than the $GL(2,\mathbb{Z}) \times G$ orbits.

Group 27 is the only case where the pairs (g, h) and (g^{-1}, h^{-1}) are not conjugated within M_{24}. Thus, charge conjugation gives the identities $\phi_{\mathrm{2B},\mathrm{8A}_1} = \phi_{\mathrm{2B},\mathrm{8A}_2}$, $\phi_{\mathrm{8A},\mathrm{2B}_1} = \phi_{\mathrm{8A},\mathrm{2B}_2}$, and so on, and the respective functions are denoted in table 2 by $\phi_{\mathrm{2B},\mathrm{8A}_{1,2}}$, $\phi_{\mathrm{8A},\mathrm{2B}_{1,2}}$, etcetera. Because of (11), most of the functions satisfy a 'reality' condition of the form

$$\phi^*_{g,h} = \zeta\, \phi_{g,h} \ , \tag{25}$$

for some constant phase ζ, which implies that the Fourier coefficients of $\zeta^{1/2}\phi_{g,h}$ are all real. Note that even if $\phi^*_{g,h}$ and $\phi_{g,h}$ are not proportional to one another, they are necessarily related by a modular transformation because of (23); if this is the case, they are listed as distinct functions in the same orbit in $\bar{\mathcal{P}}$.

Most of the modular groups $\Gamma_{g,h}$ are of the form $\Gamma(1) = SL(2,\mathbb{Z})$ or

$$\Gamma_0(N) := \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid c \equiv 0 \mod N\} \ , \tag{26}$$

or conjugates of $\Gamma_0(N)$ in $SL(2,\mathbb{Z})$. The exceptions are the group in case 32, where

$$\Gamma_{\mathrm{2B},\mathrm{10A}} = \bigcup_{i\in\mathbb{Z}/3\mathbb{Z}, j\in\mathbb{Z}/4\mathbb{Z}} \left(\begin{smallmatrix} 1 & 1 \\ -5 & -4 \end{smallmatrix}\right)^i \left(\begin{smallmatrix} -3 & -1 \\ 10 & 3 \end{smallmatrix}\right)^j \Gamma_{2,10} \ , \tag{27}$$

is a subgroup of index 12 in $SL(2,\mathbb{Z})$ and

$$\Gamma_{2,10} := \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid a \equiv 1,\ b \equiv 0 \mod 2,\ c \equiv 0,\ d \equiv 1 \mod 10\} \ , \tag{28}$$

is the group of elements $\gamma \in SL(2,\mathbb{Z})$ such that $(g, h)\cdot\gamma = (g, h)$; the group in case 12, with

$$\Gamma_{\mathrm{2A},\mathrm{4A}} = \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid b \equiv 0 \mod 2, c \equiv 0 \mod 4\} \ , \tag{29}$$

which is a conjugate of $\Gamma_0(8)$ in $SL(2,\mathbb{R})$; and the group in case 22, with

$$\Gamma_{\mathrm{4A},\mathrm{4C}} = \langle \left(\begin{smallmatrix} -1 & 1 \\ -2 & 1 \end{smallmatrix}\right) \ , \ \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right) \ , \ \left(\begin{smallmatrix} 1 & 0 \\ 4 & 1 \end{smallmatrix}\right) \ , \ \left(\begin{smallmatrix} 3 & -2 \\ -4 & 3 \end{smallmatrix}\right) \rangle \ . \tag{30}$$

2.5. **Explicit twining genera.** We have now reduced our problem to finding 34 functions $\phi_{g,h}$ that are weak Jacobi forms with respect to $\Gamma_{g,h}$ up to some multiplier phases. As will be explained in the following section 3, our assumption (E) allows us to determine the precise form of these multipliers explicitly. Then most of the 34 functions vanish because of the obstructions, see table 3. For those that do not, the modular properties are strong enough to determine them explicitly, see also table 3. These explicit results are one of the main results of this paper, and their derivation is sketched in section 3, see in particular section 3.4, as well as appendix A. As will be explained below in section 3.5, these functions

#	Structure	Functions	$\Gamma_{g,h}$
1.	$\mathbb{Z}_2 \times \mathbb{Z}_2$	$\phi_{\mathrm{2A,2A_2}}$	$\Gamma(1)$

TABLE 3. For each of the 34 cases we give here the explicit result for the twisted twining genus, as well as where applicable, the obstruction that it responsible for its vanishing.

are also compatible with the expected projective representation of the centraliser $C_{M_{24}}(g)$ on the g-twisted sector, see property (C) in section 2.

3. HOLOMORPHIC ORBIFOLDS AND GROUP COHOMOLOGY

In this section we review the modular properties of holomorphic orbifolds since, according to our assumption (E), these are also relevant for the twisted twining genera of K3. We then explain how, in our context, the known multiplier phases of the twining genera determine the underlying 3-cocycle $\alpha \in H^3(M_{24}, U(1))$ uniquely, and how to obtain from this our explicit results given in table 3. Finally, we shall check that these formulae indeed give rise to the appropriate projective representations of the centraliser $C_{M_{24}}(g)$.

3.1. **Review of holomorphic orbifolds.** Suppose $\mathcal{C}$ is a self-dual VOA, and G is a group of $\mathcal{C}$-automorphisms. We are interested in the 'orbifold' of $\mathcal{C}$ by G. To this end we consider the G-invariant sub-VOA of $\mathcal{C}$,

$$\mathcal{C}^G = \{\psi \in \mathcal{C} : g\psi = \psi, \, \forall g \in G\} \ . \tag{31}$$

Each representation of $\mathcal{C}$ gives rise to a representation of $\mathcal{C}^G$. In addition, there are new representations of $\mathcal{C}^G$ that appear in the different twisted sectors $\mathcal{C}_A$; since $\mathcal{C}$ is holomorphic there is a unique twisted sector $\mathcal{C}_A$ for each conjugacy class A in G.

3.1.1. *Twisted twining characters.* Each twisted sector $\mathcal{C}_A$ defines a representation of the G-invariant sub-VOA $\mathcal{C}^G$, but it is typically not irreducible. In particular, for each g_A in the conjugacy class $g_A \in [A]$, we can project $\mathcal{C}_{g_A}$ onto a $\mathcal{C}^G$-invariant subspace using any (projective) character χ of $C_G(g_A)$. Thus we can label the irreducible representations of $\mathcal{C}^G$ by pairs (A, χ). In physics, by the orbifold of $\mathcal{C}$ by G one usually means the theory where one chooses $\chi = 1$ in each twisted sector, i.e. the full partition function takes the form

$$Z_{\rm orb}(\tau) = \sum_A \frac{1}{|C_G(A)|} \sum_{h \in C_G(g_A)} Z_{g_A,h}(\tau) \ , \tag{32}$$

where

$$Z_{g,h}(\tau) \equiv {}_g\underset{h}{\boxed{}} = \mathrm{Tr}_{\mathcal{C}_g} \left(\rho_g(h) \, q^{L_0 - \frac{c}{24}} \right) \ , \tag{33}$$

and ρ_g denotes the action of $C_G(g)$ on $\mathcal{C}_g$. We should mention that this action is usually *not* canonically defined; for example, what is usually referred to as discrete torsion [33] can be thought of as being an ambiguity in the definition of ρ_g. Incidentally, the fact that the action is not canonically defined will be important to us later, see in particular section 4.1. For the moment though, we want to assume that such an action has been chosen.

3.1.2. *Projective representations.* As alluded to above, the twisted sectors $\mathcal{C}_g$ typically do not form genuine representations of $C_G(g)$ but only *projective representations.* A projective representation ρ of a finite group G is characterised by the relation (see also appendix C for some introductory comments)

$$\rho(g_1) \, \rho(g_2) = c(g_1, g_2) \, \rho(g_1 g_2) \ , \tag{34}$$

where $c : G \times G \to U(1)$ is a (normalised) 2-cocycle representing a cohomology class in $H^2(G, U(1))$. Genuine representations of finite groups are classified, up to equivalence, by their characters $\mathrm{Tr}_\rho(h)$. This is, however, no longer true for projective representations since taking the trace over a projective representation does not lead to a class function, i.e. a function that is invariant under conjugation by elements in G. Instead, for projective representations one has

$$\mathrm{Tr}_\rho(hgh^{-1}) = \frac{c(h,h^{-1}gh)}{c(g,h)}\,\mathrm{Tr}_\rho(g)\ , \tag{35}$$

as follows from the defining relation (34) together with the cyclicity of the trace (see e.g. [34] for a nice discussion). For the case of the holomorphic orbifold, this then results in the conjugation relation

$$Z_{g,h}(\tau) = \frac{c_g(h,k)}{c_g(k,k^{-1}hk)}\,Z_{k^{-1}gk,k^{-1}hk}(\tau)\ , \tag{36}$$

where the 2-cocycle c_g represents a class in $H^2(C_G(g),U(1))$ specifying the projective representation of the centralizer $C_G(g)$ on $\mathcal{C}_g$, and we have assumed that k and g commute so that both expressions are evaluated in the same twisted sector. (In fact, (36) is even true if k and g do not commute, see [25].) If in addition k commutes with h, (36) reduces to

$$Z_{g,h}(\tau) = \frac{c_g(h,k)}{c_g(k,h)}\,Z_{g,h}(\tau)\ , \tag{37}$$

which therefore implies that $Z_{g,h}$ vanishes unless the 2-cocycle is *regular*,

$$c_g(h,k) = c_g(k,h)\ . \tag{38}$$

This is the holomorphic orbifold version of the first type of obstruction discussed in section 2.2 above.

3.1.3. *The underlying cohomology.* The possible choices for the 2-cocycles c_g in the various twisted sectors are constrained; for example this follows from demanding consistency of the OPE involving fields from different twist sectors.[‖] In particular, it was argued in [25] that the various consistent choices are in one-to-one correspondence with elements in the third cohomology group $[\alpha] \in H^3(G,U(1))$, see also [35, 36, 37, 38] for subsequent work. The 3-cocycle α determines distinguished elements $c_g \in H^2(C_G(g),U(1))$ via the formula [25, 35]

$$c_g(h_1,h_2) = \frac{\alpha(g,h_1,h_2)\,\alpha(h_1,h_2,(h_1h_2)^{-1}g(h_1h_2))}{\alpha(h_1,h_1^{-1}gh_1,h_2)}\ . \tag{39}$$

Since α fixes all 2-cocylces c_g via (39), it is clear that the choice of α determines the behaviour of the twisted twining characters under conjugation (36). Furthermore, α also

---

[‖] This origin of the constraint was suggested in [36].

determines all the multiplier phases that appear under modular transformations, since it follows from [35] that[**]

$$\begin{aligned} Z_{g,h}(\tau+1) &= c_g(g,h)\, Z_{g,gh}(\tau)\ , \\ Z_{g,h}(-1/\tau) &= \overline{c_h(g,g^{-1})}\, Z_{h,g^{-1}}(\tau)\ . \end{aligned} \tag{40}$$

The choice of a particular representative α in the class $[\alpha] \in H^3(G,U(1))$ corresponds to a choice of normalisation for the action of h on the g-twisted sector. To see this, let $\tilde{\alpha}$ represent a 3-cocycle in the same cohomology class $[\alpha] \in H^3(G,U(1))$, so that $\tilde{\alpha} = \alpha \cdot \partial\beta$ (see eq. (158)) for some 2-cochain β. Then the associate 2-cocycles c_g and $\tilde{c}_g$ differ (for each $g \in G$) only by a 2-coboundary i.e. $\tilde{c}_g = c_g \cdot \partial\gamma_g$, with $\gamma_g(h) = \frac{\beta(h,g)}{\beta(g,h)}$, see appendix B. Thus, the 3-cocycle $\tilde{\alpha}$ is associated with the modular properties of the functions $\tilde{Z}_{g,h} = \gamma_g(h) Z_{g,h}$, which, by (33), simply correspond to a different normalisation $\tilde{\rho}_g(h) = \gamma_g(h)\rho_g(h)$ for the action of h on the g-twisted sector.

3.2. **Application to Mathieu Moonshine.** Given what we said before, it is now natural to postulate that for the twisted twining genera of K3, the various multiplier phases also come from a 3-cocycle $\alpha \in H^3(M_{24},U(1))$. This is to say, we postulate that the projective representation appearing in (C) is the one determined by c_g, given by (39). Furthermore, $\chi_{g,h}\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ in (4) is determined by (40), and $\xi_{g,h}(k)$ in (5) agrees with (37), where in both cases c_g is again the function determined by (39) for a fixed $\alpha \in H^3(M_{24},U(1))$. More explicitly, we therefore propose that

$$\begin{aligned} &\phi_{g,h}\left(-\tfrac{1}{\tau},\tfrac{z}{\tau}\right) = \overline{c_h(g,g^{-1})}\, e^{2\pi i \frac{z^2}{\tau}}\, \phi_{h,g^{-1}}(\tau,z)\ , \\ &\phi_{g,h}(\tau+1,z) = c_g(g,h)\, \phi_{g,gh}(\tau,z)\ , \end{aligned} \tag{41}$$

with $c_g(h_1,h_2)$ given by (39), and

$$\phi_{g,h}(\tau,z) = \frac{c_g(h,k)}{c_g(k,k^{-1}hk)}\, \phi_{k^{-1}gk,k^{-1}hk}(\tau,z)\ , \qquad k \in M_{24}\ . \tag{42}$$

Moreover, we postulate that

$$\phi_{g,h^{-1}}(\tau,z) = c_g(h,h^{-1})\, \phi^*_{g,h}(\tau,z)\ , \tag{43}$$

where $\phi^*_{g,h}(\tau,z)$ is defined in (12).

[**] Note that (40) is obtained from [35] upon working with the inverse 3-cohomology element. We also thank Terry Gannon for explaining these formulae to us. It is believed (and we have verified this in simple cases) that (40) follows from the transformation rules for the irreducible orbifold characters, see [37, eqs. (5.23) and (5.24)], but we have not proven this in complete generality.

Combining modular transformations with conjugation one obtains a whole set of relations among the twisted twining genera, where the multipliers are given by

$$\chi_{g,h}(\gamma_1\gamma_2) = \chi_{g,h}(\gamma_1)\,\chi_{(g,h)\gamma_1}(\gamma_2)\ , \qquad \gamma_1,\gamma_2 \in SL(2,\mathbb{Z})\ , \tag{44}$$

$$\chi_{g,h}\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = \frac{1}{c_h(g,g^{-1})}\ , \tag{45}$$

$$\chi_{g,h}\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) = c_g(g,h)\ , \tag{46}$$

$$\chi_{g,h}\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = \frac{1}{c_g(h,h^{-1})}\ , \tag{47}$$

$$\xi_{g,h}(k) = \frac{c_g(h,k)}{c_g(k,k^{-1}hk)}\ . \tag{48}$$

Since $SL(2,\mathbb{Z})$ is generated by $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ and $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ with the only relations being $S^4 = 1$ and $(ST)^3 = S^2$, it follows that eqs. (44) – (47) determine the multiplier $\chi_{g,h}(\gamma)$, $\gamma \in SL(2,\mathbb{Z})$, provided that the following consistency conditions are satisfied

$$\chi_{g,h}(S^4) = 1\ , \qquad \chi_{g,h}((ST)^3) = \chi_{g,h}(S^2)\ . \tag{49}$$

Furthermore, since the actions of $SL(2,\mathbb{Z})$ and M_{24} on the set $\mathcal{P}$ commute with one another, there are two more consistency conditions

$$\xi_{g,h}(k)\,\chi_{k^{-1}gk,k^{-1}hk}(\gamma) = \chi_{g,h}(\gamma)\,\xi_{(g,h)\gamma}(k) \qquad \xi_{g,h}(k)\,\xi_{k^{-1}gk,k^{-1}hk}(k') = \chi_{g,h}(kk')\ , \tag{50}$$

for all $\gamma \in SL(2,\mathbb{Z})$ and $k,k' \in M_{24}$. In fact, conditions (49) and (50) hold for a generic group G, and can be easily checked using standard identities for the cocycle c_g, in particular, eqs. (3.2.5)–(3.2.9) of [36] (see also [35]).

Note that the charge conjugation operator $C = S^2$ acts on the genera $\phi_{g,h}(\tau,z)$ by flipping the sign of the second argument z. In fact, writing $\tau = -\frac{1}{\tilde\tau}$ and $z = \frac{\tilde z}{\tilde \tau}$, we get from twice applying (41)

$$\begin{aligned}\phi_{g,h}(\tau,z) = \phi_{g,h}(-\tfrac{1}{\tilde\tau},\tfrac{\tilde z}{\tilde\tau}) &= \frac{e^{2\pi i\frac{\tilde z^2}{\tilde\tau}}}{c_h(g,g^{-1})}\,\phi_{h,g^{-1}}(\tilde\tau,\tilde z) \\ &= \frac{e^{-2\pi i\frac{z^2}{\tau}}}{c_h(g,g^{-1})}\,\phi_{h,g^{-1}}(-\tfrac{1}{\tau},-\tfrac{z}{\tau}) = \frac{1}{c_h(g,g^{-1})c_{g^{-1}}(h,h^{-1})}\,\phi_{g^{-1},h^{-1}}(\tau,-z)\ ,\end{aligned} \tag{51}$$

so that

$$\chi_{g,h}\left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = \frac{1}{c_h(g,g^{-1})c_{g^{-1}}(h,h^{-1})}\ . \tag{52}$$

Together with (13), this then leads to

$$\phi_{g,h}(\tau,z) = \frac{1}{c_h(g,g^{-1})\,c_{g^{-1}}(h,h^{-1})}\,\phi_{g^{-1},h^{-1}}(\tau,z)\ , \tag{53}$$

thus reproducing (17). This identity played a key role in the derivation of obstruction 2 in section 2.2.

While our proposal about the multiplier phases is certainly natural, we do not have a direct proof for it. However, the fact that with this assumption we shall find consistent answers is in our opinion very convincing evidence in favour of this ansatz.

3.3. Determining the cohomology class.

In order to have explicit formulae for the multipliers, the next step consists of determining $[\alpha] \in H^3(M_{24}, U(1))$. In this subsection, we will prove (with some computer support) that there exists a unique cohomology class $[\alpha]$ that reproduces (10) for all the *untwisted* twining genera $\phi_{e,g}(\tau, z)$. Since this is an overdetermined problem, the existence of such class already represents a non-trivial consistency check for our proposal. In the following subsections, we will then explain how the remaining twisted twining characters can be computed, once the class $[\alpha]$ is known.

First we note that the normalisation condition for α, see eq. (159), implies that $c_e(g,h) = 1$ for all $g, h \in M_{24}$. Thus $\phi_{e,g}(\tau+1, z) = \phi_{e,g}(\tau, z)$, $\phi_{e,g^{-1}}(\tau, z) = \phi_{e,g}(\tau, z)$ and $\phi_{e,g}(\tau, z) = \phi_{e,k^{-1}gk}(\tau, z)$ for all $k \in M_{24}$, as expected. Furthermore, the representation ρ_e in the decomposition (6) is a genuine representation of $C_{M_{24}}(e) = M_{24}$.

Next we observe that eq. (41) implies

$$\phi_{g^a,g^b}(\tau + o(g^a), z) = \kappa(g^a, g^b)\, \phi_{g^a,g^b}(\tau, z) \ , \tag{54}$$

where

$$\kappa(g^a, g^b) := \prod_{k=1}^{o(g^a)} c_{g^a}(g^a, g^{b+ak}) = \prod_{k=1}^{o(g^a)} \alpha(g^a, g^{b+ak}, g^a) \ . \tag{55}$$

More precisely, the phases $\kappa(g^a, g^b)$ are the multipliers of $\phi_{e,g}$ under certain parabolic elements of the form

$$\gamma \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} \gamma^{-1} \in \Gamma_0(o(g)) \ , \tag{56}$$

where $\gamma \in SL(2, \mathbb{Z})$ is such that $(e, g)\gamma = (g^a, g^b)$ and $n = o(g^a)$. By comparing such a multiplier with the one expected from (10), one obtains the following condition

$$\kappa(g^a, g^b) = e^{-\frac{2\pi i}{\ell(g^a)}} \ , \tag{57}$$

for all $a, b \in \mathbb{Z}$, where $\ell(g^a)$ is the length of the smallest cycle of g^a when considered as a permutation of 24 objects. It is easy to verify that $\kappa(g^a, g^b)$ only depends on the cohomology class of the 3-cocycle α. Thus we have to prove that there is a unique class $[\alpha] \in H^3(M_{24}, U(1))$ such that (57) is satisfied for all $g \in M_{24}$, $a, b \in \mathbb{Z}$.

In order to show that such an α exists, we first need two basic facts about group cohomology. Given two finite groups G and H and a homomorphism $\iota : H \to G$, we can define the induced map ι^* from $U(1)$-cochains α for G to $U(1)$-cochains $\iota^*(\alpha)$ for H

$$\iota^*(\alpha)(g_1, \ldots, g_n) = \alpha(\iota(g_1), \ldots, \iota(g_n)) \ , \tag{58}$$

which induces a well-defined map on cohomologies ([43], Chapter III.8). A particular case is when $H = G$ and the map $H \to G$ is conjugation $\iota_k(g) = k^{-1}gk$ by an element $k \in G$. In this case, the induced map on the cohomology ι_k^* acts as the identity, i.e. $[\iota^*(\alpha)] = [\alpha]$ (see [43], Chapter III Proposition 8.3). A second interesting case is when H is a subgroup of G with ι the natural inclusion; in this case, $\mathrm{Res} \equiv \iota^*$ is called a restriction map. In particular, if H is a Sylow p-subgroup $\mathrm{Syl}_p\, G$ of G,[††] then the image of the restriction map

$$\mathrm{Res}_p : H^n(G, U(1)) \to H^n(\mathrm{Syl}_p(G), U(1)) \tag{59}$$

is isomorphic to the p-part of $H^n(G, U(1))$ ([43], Chapter III Theorem 10.3). For $G = M_{24}$, using that $H^3(M_{24}, U(1)) \cong \mathbb{Z}_{12}$ [32], this implies

$$\mathrm{Res}_2(H^3(M_{24}, U(1))) \cong \mathbb{Z}_4 \ , \qquad \mathrm{Res}_3(H^3(M_{24}, U(1))) \cong \mathbb{Z}_3 \ , \tag{60}$$

while $\mathrm{Res}_p(H^3(M_{24}, U(1)))$ is trivial for all primes $p > 3$.

With these preparations we can now turn to the proof that a unique class $[\alpha] \in H^3(M_{24}, U(1))$ satisfying (57) exists. From the invariance of the cohomology classes under the conjugation map ι_k^*, it follows that the multiplier in (57) only depends on the conjugacy class of g. Next we note that in order to compute $\kappa(g^a, g^b)$, it is sufficient to consider the restriction of the cocycle α to the group $\langle g \rangle$ generated by g. For a cyclic group $\mathbb{Z}_N$, the third cohomology $H^3(\mathbb{Z}_N, U(1))$ is isomorphic to $\mathbb{Z}_N$, and a set of cocycle representatives for the cohomology classes are given by [44, 37]

$$\omega_q(g^a, g^b, g^c) = e^{2\pi i \frac{qa}{o(g)^2}([b]+[c]-[b+c])} \ , \qquad q = 0, \ldots, o(g) - 1 \ , \tag{61}$$

where $[\cdot] : \mathbb{Z} \to \{0, \ldots, o(g) - 1\}$ is the reduction modulo $o(g)$.

Let us assume, without loss of generality, that $1 \le a < o(g) - 1$ and $0 \le b < a$, and that a divides $o(g)$; in fact, if this was not true, we can rewrite both g^a and g^b as powers of another

---

[††] Recall that a p-group (p prime) is a finite group with order a power of p; a Sylow p-subgroup of a group G is a p-subgroup of G that is maximal, i.e. that is not properly contained in any other p-subgroup. For each p, all Sylow p-subgroups of G are isomorphic and conjugate to one another inside G.

$\tilde{g}$ in $\langle g\rangle$ for which this is then true. The multiplier corresponding to a 3-cocycle ω_q is

$$\begin{aligned}\kappa(g^a,g^b) &= \prod_{k=0}^{o(g^a)-1}\omega_q(g^a,g^{b+ak},g^a) = e^{2\pi i\frac{qa}{o(g)^2}\sum_{k=0}^{o(g^a)-1}([b+ak]+[a]-[b+a(k+1)])} \qquad (62)\\ &= e^{2\pi i\frac{qa}{o(g)^2}([b]+o(g^a)[a]-[b+ao(g^a)])} = e^{2\pi i\frac{qa}{o(g)}}\ ,\end{aligned}$$

where we have used that $o(g^a)=o(g)/a$ when a divides $o(g)$. Thus, $\kappa(g^a,g^b)\equiv\kappa(g^a)$ is independent of b, and $\kappa(g^a)=\kappa(g)^a$ whenever a divides $o(g)$. The latter property is consistent with (57) thanks to the identity

$$\frac{1}{\ell(g^a)}\equiv\frac{a}{\ell(g)}\mod 1\ , \qquad (63)$$

that holds for all elements $g\in M_{24}$ and for all divisors a of $o(g)$.[*]
It therefore follows that it is sufficient to prove (57) for $a=1$ and $b=0$, and for one representative g for each conjugacy class. Furthermore, thanks to $\kappa(g^a)=\kappa(g)^a$, we can restrict to classes whose order is a prime power. In other words, we only need to check (57) for a Sylow p-subgroup $\mathrm{Syl}_p(M_{24})$ and for each prime p.

Using the software `GAP` [41] with the package `HAP` [42] implemented, we have computed a basis of cocycle representatives for $H^3(\mathrm{Syl}_2(M_{24}),U(1))$ and $H^3(\mathrm{Syl}_3(M_{24}),U(1))$. Note that any 3-cocycle in the image of Res_p has the property that, for any $g\in\mathrm{Syl}_p(M_{24})$, the corresponding multiplier $\kappa(g)$ depends only on the conjugacy class of g in M_{24}. We have verified that there is a unique $\mathbb{Z}_4$ subgroup of $H^3(\mathrm{Syl}_2(M_{24}),U(1))$ and a unique $\mathbb{Z}_3$ subgroup of $H^3(\mathrm{Syl}_3(M_{24}),U(1))$ satisfying this property. Therefore these subgroups must correspond to the restrictions $\mathrm{Res}_p(H^3(M_{24},U(1)))$, for $p=2$ and $p=3$, respectively. Finally, for both $p=2$ and $p=3$, we have verified that there is a unique cohomology class $[\alpha_p]\in\mathrm{Res}_p(H^3(M_{24},U(1)))$ that satisfies (57) for all g in $\mathrm{Syl}_p(M_{24})$. Thus, the unique class $[\alpha]\in H^3(M_{24},U(1))$ that has the property that $\mathrm{Res}_p([\alpha])=[\alpha_p]$ for all primes p, satisfies (57) for all $g\in M_{24}$.

We have thus proven that there exists a unique class $[\alpha]\in H^3(M_{24},U(1))$ satisfying (57). It remains to show that this class exactly reproduces (10) for all $\phi_{e,g}$. First, we notice that the multiplier (10) of $\phi_{e,g}$ is trivial whenever the class of g restricts to a class in M_{23}. Since $H^3(M_{23},U(1))$ is trivial, this is consistent with any choice of the cocycle α. Thus, we only need to check (10) for the classes that do not restrict to M_{23}. The corresponding characters

---

[*] Note that this property is special for M_{24}, and is not true for a generic permutation.

$\phi_{e,g}$ are Jacobi forms under $\Gamma_0(o(g))$, where the possible orders $o(g)$ are $2, 3, 4, 6$ and 12. For $N = 2, 3, 4$, the group $\Gamma_0(N)$ is generated by

$$T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} , \qquad C = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} , \qquad \begin{pmatrix} 1 & 0 \\ -N & 1 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} T^N \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \tag{64}$$

while $\Gamma_0(6)$ is generated by T, C, together with

$$\begin{pmatrix} 1 & 0 \\ -6 & 1 \end{pmatrix} , \qquad \begin{pmatrix} -5 & 3 \\ -12 & 7 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix} T^3 \begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix} . \tag{65}$$

The correct modular properties (10) under T and C are automatic for any normalised cocycle α. The remaining generators are of the form (56) with $(e, g)\gamma = (g^a, g^b)$ and $n = o(g^a)$, and hence (10) follows again from (57).

The group $\Gamma_0(12)$ is generated by T, C and[†]

$$\alpha_1 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 12 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} , \qquad \alpha_2 = \begin{pmatrix} 1 & 0 \\ 3 & 1 \end{pmatrix} \begin{pmatrix} 1 & 4 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -3 & 1 \end{pmatrix} , \tag{66}$$

$$\alpha_3 = \begin{pmatrix} 1 & 0 \\ 6 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -6 & 1 \end{pmatrix} , \qquad \alpha_4 = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 3 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix} . \tag{67}$$

The generators $\alpha_1, \ldots, \alpha_4$ are of the form (56) with $(e, g)\gamma = (g^a, g^b)$, but only for α_1, α_2 is the condition $n = o(g^a)$ satisfied, and thus only in these cases is condition (57) sufficient to establish (10). The generators α_3, α_4 satisfy $(e, g)\alpha_i = (e, g^7)$, $i = 3, 4$, so one needs to conjugate by an element $k \in M_{24}$ such that $k^{-1}g^7k = g$. In order to compute the multiplier under these generators, one needs to determine the restriction of $[\alpha] \in H^3(M_{24}, U(1))$ to the subgroup of M_{24} generated by g and k. Using `GAP`, we computed a basis for the third cohomology of the group $\langle g, k\rangle$ and looked for those classes that satisfy condition (57) for all elements of the group. It turns out that there is only one such class, and hence it must correspond to the restriction of $[\alpha] \in H^3(M_{24}, U(1))$ to the cohomology of $\langle g, k\rangle$. Then it is straightforward to check that this class reproduces indeed the multipliers (10) under α_3 and α_4; this is true for both the M_{24} conjugacy classes of order 12. This completes the proof. The `GAP`-files containing the computations described above are available online [45].

[†] It is straightforward to check that $T, C, \alpha_1, \ldots, \alpha_4$ actually generate $\Gamma_0(12)$ by simply comparing them to a minimal set of generators obtained by some standard method, such as the Farey symbol algorithm.

3.4. **Computation of the twisted twining characters: an example.** In the previous subsection, we proved that there is a unique cohomology class $[\alpha] \in H^3(M_{24}, U(1))$ that reproduces the multipliers (10) for all the *untwisted* twining genera $\phi_{e,g}$. In this section, we shall explain how the remaining twisted twining genera $\phi_{g,h}$ can be determined, leading to the results collected in section 2.5.

The first step is to compute the obstructions and the multipliers for a given twisted twining genus $\phi_{g,h}$. To this end we note that it is sufficient to consider the restriction of the cocycle α to the normaliser $N(g,h)$ of $\langle g, h\rangle$. If this normaliser is contained in some Sylow p-subgroup, one can simply use the cocycle α_p determined in the previous subsection. Otherwise, one can use `GAP` to compute a basis for the cohomology of $N(g,h)$ and check which cohomology classes reproduce the correct multipliers (and in particular (57)) for all genera of the form $\phi_{e,k}$, $k \in N(g,h)$. In all cases we considered, there was only one cohomology class with this property, which must therefore be the restriction of the class $[\alpha] \in H^3(M_{24}, U(1))$ to the cohomology of $N(g,h)$. Once the restriction of $[\alpha]$ to $N(g,h)$ is determined, one can check the existence of obstructions for all 34 groups of table 1. The results are collected in table 3 and the `GAP`-files containing these computations are available online [45].

For the six unobstructed twisted twining genera $\phi_{g,h}$, one can compute the precise multiplier system. It turns out that this information is sufficient to determine $\phi_{g,h}$ up to normalisation. The normalisation can be fixed (up to a phase) by requiring that a decomposition (6) exists. In the remainder of this subsection, we illustrate how one of these non-zero twisted twining genera, namely the one associated to $g \in 2\mathrm{B}$ and $h \in 8\mathrm{A}$, can be determined explicitly; the other five cases are completely analogous and are dealt with in appendix A. Let us work with the conventions that the three permutations

$$(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23)(24)\ ,$$
$$(3,17,10,7,9)(4,13,14,19,5)(8,18,11,12,23)(15,20,22,21,16)(1)(2)(6)(24)\ ,$$
$$(1,24)(2,23)(3,12)(4,16)(5,18)(6,10)(7,20)(8,14)(9,21)(11,17)(13,22)(15,19)$$

generate $M_{24} \subset S_{24}$. As representative for $g \in 2\mathrm{B}$ we can then take

$$g = (1,10)(2,14)(3,8)(4,5)(6,22)(7,20)(9,18)(11,23)(12,24)(13,19)(15,16)(17,21)\ , \quad (68)$$

while for $h \in 8\mathrm{A}$ we consider

$$h = (2,14)(3,9,8,18)(4,6,21,19,15,24,20,11)(5,22,17,13,16,12,7,23)(1)(10)\ . \quad (69)$$

The elements g, h generate the abelian group $\mathbb{Z}_2 \times \mathbb{Z}_8$ corresponding to case 27 of table 1. There are two interesting conjugation relations, namely

$$(k^{-1}gh^4k\,,\,k^{-1}h^{-1}k) = (g,h)\ , \qquad (r^{-1}gr\,,\,r^{-1}ghr) = (g,h)\ , \tag{70}$$

where

$$\begin{aligned} k &= (1,10)(2,14)(3,18)(4,11)(5,13)(6,20)(7,12)(8,9)(15,19)(16,23)(17,22)(21,24)\ ,\\ r &= (1,2)(3,9)(6,22)(8,18)(10,14)(11,23)(12,24)(13,19)(4)(5)(7)(15)(16)(17)(20)(21)\ . \end{aligned} \tag{71}$$

Thus, we can use the general formulae (41) and their inverses to deduce that[‡]

$$\phi_{g,h}(\tau+1) = c_g(g,h)\phi_{g,gh}(\tau) = c_g(g,h)\frac{c_g(gh,r)}{c_g(r,h)}\phi_{g,h}(\tau) = i\phi_{g,h}(\tau)\ , \tag{72}$$

where we have used the explicit form of the multiplier factors from section 3.3. We also have (recall that $g = g^{-1}$)

$$\begin{aligned} \phi_{g,h}(\tfrac{\tau}{-4\tau+1}) &= \frac{\phi_{h,g}(4-\frac{1}{\tau})}{c_h(g,g)} = \frac{\prod_{i=1}^{3} c_h(h,gh^i)}{c_h(g,g)}\phi_{h,gh^4}(-\tfrac{1}{\tau}) = \frac{\prod_{i=1}^{3} c_h(h,gh^i)}{c_h(g,g)c_{gh^4}(h,h^{-1})}\phi_{gh^4,h^{-1}}(\tau)\\ &= \frac{\prod_{i=1}^{3} c_h(h,gh^i)}{c_h(g,g)c_{gh^4}(h,h^{-1})}\frac{c_{g^4h}(h^{-1},k)}{c_{g^4h}(k,h)}\phi_{g,h}(\tau) = -\phi_{g,h}(\tau)\ . \end{aligned} \tag{73}$$

This implies that $\phi_{g,h}(\tau,z)$ is a Jacobi form under the group $\Gamma_0(4)$ with the above multipliers. Let us consider now the dependence of $\phi_{g,h}(\tau,z)$ on z, for a fixed $\tau \in \mathbb{H}_+$. The characters $\mathrm{ch}_{h,\ell}(\tau,z)$ of the $\mathcal{N}=4$ algebra are even functions of z and $\mathrm{ch}_{h,\ell}(\tau,z=0)$ is independent of τ (in particular, $\mathrm{ch}_{h,\ell}(\tau,0)=0$ for $h>1/4$) [31]. By (6), all twisted-twining genera must satisfy the same properties. Since the multiplier system for $\phi_{g,h}$ is non-trivial, the constant $\phi_{g,h}(\tau,0)$ must vanish and by $\phi_{g,h}(\tau,z)=\phi_{g,h}(\tau,-z)$ it follows that $\phi_{g,h}$ has a double zero at $z=0$ (mod $\mathbb{Z}+\tau\mathbb{Z}$). Every (weak) Jacobi form of index 1 has exactly two zeros (counting multiplicity) in each fundamental domain of $\mathbb{C}/(\mathbb{Z}+\tau\mathbb{Z})$ [30], so that these are the only zeroes of $\phi_{g,h}(\tau,z)$. On the other hand, the function

$$\psi(\tau,z) \equiv \frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2} \tag{74}$$

is also a Jacobi form weight 0 and index 1 under $\Gamma_0(4)$ (with trivial multiplier) and has only a double zero at $z=0$ (mod $\mathbb{Z}+\tau\mathbb{Z}$). It therefore follows that

$$F(\tau) \equiv \frac{\phi_{g,h}(\tau,z)}{\psi(\tau,z)} \tag{75}$$

[‡] For brevity of presentation we omit the dependence of z, as well as the factors $e^{2\pi i\frac{cz^2}{c\tau+d}}$, in the following formulae.

is independent of z and is a modular function of weight 0 under $\Gamma_0(4)$ (with multiplier system (72)–(73)) that is holomorphic in the interior of $\mathbb{H}_+$. Let us consider the asymptotic behaviour of $F(\tau)$ at the boundary $\Gamma_0(4)\backslash(\mathbb{Q}\cup\{\infty\})$ of the compactification $\Gamma_0(4)\backslash\bar{\mathbb{H}}_+$. This boundary consists of three points (cusps) of the form $\gamma_c\cdot\infty$, where $\gamma_\infty = \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, $\gamma_0 = \left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right)$ and $\gamma_{1/2} = \left(\begin{smallmatrix}1&0\\2&1\end{smallmatrix}\right)$. The twisted twining genus $\phi_{g,h}$ has the Fourier expansion at these cusps

$$\phi_{g,h}(\gamma_\infty(\tau,z)) = \phi_{g,h}(\tau,z) = A_\infty\, q^{1/4}(2-y-y^{-1}) + O(q^{5/4}) \tag{76}$$

$$\phi_{g,h}(\gamma_0(\tau,z)) \sim \phi_{h,g}(\tau,z) = A_0\, q^{1/8}(2-y-y^{-1}) + O(q^{3/8}) \tag{77}$$

$$\phi_{g,h}(\gamma_{1/2}(\tau,z)) \sim \phi_{gh^2,h}(\tau,z) = A_{1/2}\, q^{1/4}(2-y-y^{-1}) + O(q^{3/4})\ , \tag{78}$$

where $\sim$ denotes equality up to a phase, and we have included the lowest non-negative powers of q^r that are compatible with the multiplier system. It follows from (6) that the constants A_∞, A_0, $A_{1/2}$ equal

$$A_\infty = \mathrm{Tr}_{\mathcal{H}_{g,r=\frac{1}{4}}}(\rho_{g,\frac{1}{4}}(h))\ , \quad A_0 = \mathrm{Tr}_{\mathcal{H}_{h,r=\frac{1}{8}}}(\rho_{h,\frac{1}{8}}(g))\ , \quad A_{1/2} = \mathrm{Tr}_{\mathcal{H}_{gh^2,r=\frac{1}{4}}}(\rho_{gh^2,\frac{1}{4}}(h))\ , \tag{79}$$

and from the Fourier expansion of $\phi_{h,e}$ we know that $\dim\mathcal{H}_{h,r=\frac{1}{8}} = 1$, so that $|A_0| = 1$. On the other hand, at the cusps $\psi(\tau,z)$ satisfies

$$\psi(\gamma_\infty(\tau,z)) = \psi(\gamma_{1/2}(\tau,z)) = \frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2} = \frac{1}{4}(2-y-y^{-1}) + O(q) \tag{80}$$

$$\psi(\gamma_0(\tau,z)) = \frac{\vartheta_1(\tau,z)^2}{\vartheta_4(\tau,0)^2} = q^{1/4}(2-y-y^{-1}) + O(q^{3/4})\ , \tag{81}$$

and we therefore obtain

$$F(\gamma_\infty\cdot\tau) = 4\,A_\infty\, q^{1/4} + O(q^{5/4}) \tag{82}$$

$$F(\gamma_0\cdot\tau) \sim A_0\, q^{-1/8} + O(q^{1/8}) \tag{83}$$

$$F(\gamma_{1/2}\cdot\tau) \sim 4\,A_{1/2}\, q^{1/4} + O(q^{3/4})\ . \tag{84}$$

Up to a phase, there is a unique modular form with the correct modular properties and the expected Fourier expansion at the cusps, namely

$$F(\tau) = 8\frac{\eta(2\tau)^6}{\eta(\tau)^6}\ . \tag{85}$$

Thus we conclude that, up to an overall phase, we have

$$\phi_{2\mathrm{B},8\mathrm{A}_{1,2}}(\tau,z) = 8\frac{\eta(2\tau)^6}{\eta(\tau)^6}\frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2} = 2\frac{\eta(2\tau)^2}{\eta(\tau)^4}\vartheta_1(\tau,z)^2\ , \tag{86}$$

where we used the identity $\vartheta_2(\tau,0)^2 = 4\frac{\eta(2\tau)^4}{\eta(\tau)^2}$. The other non-trivial cases can be worked out similarly; see appendix A for the details.

3.5. **Projective representations.** As we have argued above, see property (C) in section 2, the twisted sector $\mathcal{H}_g$ should carry a projective representation of the centraliser $C_{M_{24}}(g)$, whose 2-cocycle is given by c_g as determined in (39). Given our explicit knowledge of all twisted twining genera as well as c_g, this can now be tested as in [8] (where the corresponding analysis was performed for the case of the twining genera): if each $\mathcal{H}_{g,r}$ is a projective representation of $C_{M_{24}}(g)$, we can decompose it as

$$\mathcal{H}_{g,r} = \bigoplus_j h^{(j)}_{g,r}\, R_j \ , \tag{87}$$

where $h^{(j)}_{g,r}$ is the multiplicity with which the irreducible projective representation R_j (whose projectivity is characterised by c_g) appears in $\mathcal{H}_{g,r}$. On the other hand, using the orthogonality of group characters (see appendix C), we can calculate $h^{(j)}_{g,r}$ from the knowledge of the twisted twining genera explicitly. The consistency condition is then that all $h^{(j)}_{g,r}$ are indeed (non-negative) integers. We have done this analysis for all twisted sectors and for the first 500 levels (i.e. the first 500 values for r), and the multiplicities are indeed always non-negative integers. The explicit results for the first 20 levels as well as the (projective) character tables of all non-isomorphic centralisers $C_{M_{24}}(g)$ are given in appendix D. The decompositions for all g and for the first 500 levels are available online [45].

4. K3 Orbifolds

There are at least two further consistency checks on our proposal that can be fairly easily analysed. Suppose we consider a K3 sigma-model $\mathcal{C}$ whose automorphism group contains the cyclic subgroup generated by g. Then we can consider the orbifold of $\mathcal{C}$ by $G = \langle g\rangle$. A priori, it is not guaranteed that this orbifold is consistent — indeed, since these symmetries effectively act asymmetrically, they generically suffer from the level-matching problem, and hence may be inconsistent [39]. However, as was already mentioned in [40], the level-matching condition is satisfied provided that the twining genus ϕ_g has a trivial multiplier system. This is in particular the case if $g \in M_{23}$. In that case, the resulting orbifold theory $\widehat{\mathcal{C}} = \mathcal{C}/G$ is again a K3 sigma model, as was also shown in [40].

Suppose then that the original $\mathcal{C}$ has, in addition to $g \in M_{23}$, another commuting group element h in its automorphism group. Then h also gives rise to a symmetry $\hat{h}$ of the orbifold theory $\widehat{\mathcal{C}}$, and we can calculate the twining genus of $\hat{h}$ by the usual orbifold formula

$$\phi_{e,\hat{h}} = \frac{1}{o(g)} \sum_{i,j=0}^{o(g)-1} \phi_{g^i,hg^j} \ . \tag{88}$$

This leads to a non-trivial consistency condition: given our explicit knowledge of all twisted twining genera, we can calculate the right-hand-side explicitly, and this must agree, for every h, with *one* of the twining genera of [8, 9]. We have checked that this is indeed true; an example is illustrated in section 4.2.

Naively, one may have guessed that $\hat{h}$ should simply agree with h, i.e. that the left-hand-side of (88) is the twining genus associated to the *same* group element $h \in M_{24}$. However, this is in general not the case, as will be explained in the following section 4.1, see also section 4.2 for an explicit example. Whenever this happens we will say that the group element h has been *relabelled* in the orbifold theory.

The other consistency check is even more obvious. As was mentioned at the beginning of section 2, there exist K3 sigma-models with a commuting pair of automorphisms (g, h). For them (2) can be calculated directly, and thus compared to our answers. We shall perform this computation for some simple cases in section 4.3. In particular, we shall concentrate on examples where our obstruction analysis predicts that the associated twisted twining genus must vanish. The fact that we can reproduce this result using elementary methods is a good consistency check on our analysis.

4.1. **The relabelling phenomenon.**

Suppose that a K3 sigma-model $\mathcal{C}$ contains in its automorphism group an element g such that the orbifold of $\mathcal{C}$ by g, $\hat{\mathcal{C}} = \mathcal{C}/\langle g\rangle$ is consistent. In general, each g^r-twisted sector carries a projective representation of $H \equiv C_{M_{24}}(g)$. Equivalently, we can think of the untwisted and twisted sectors as carrying genuine representations of some central extension $\tilde{H}$ of H. In fact, the central extension can be chosen to be of the form (see also appendix C.1 for more details)

$$1 \to \langle\tilde{Q}\rangle \cong \mathbb{Z}_N \to \tilde{H} \xrightarrow{\rho} H \to 1 \ . \tag{89}$$

Here ρ is the representation in the untwisted sector, i.e. on the spectrum of $\mathcal{C}$, N is the order $o(g)$ of g and the generator $\tilde{Q}$ (that we call the *quantum symmetry*) of the central $\mathbb{Z}_N$ acts by $e^{2\pi i r/N}$ on the g^r-twisted sector. Note that there is always a lift $\tilde{g} \in \tilde{H}$ of g that acts by $e^{2\pi i k/N}$ on the states of conformal weight $h - 1/4 = k/N$.

In the orbifold theory $\hat{\mathcal{C}}$, all states are invariant under the action of $\tilde{g}$ — this is just the precise way of imposing the usual requirement that the orbifold theory consists of 'g-invariant' states only. Since $\tilde{g}$ is in the center of $\tilde{H}$, the spectrum of $\hat{\mathcal{C}}$ carries a well-defined representation $\hat{\rho}$ of $\tilde{H}$, such that $\hat{\rho}(\tilde{g})$ is the identity. In fact, it is easy to see that $\ker\hat{\rho} = \langle\tilde{g}\rangle$, because $\tilde{Q}$ acts non-trivially on the twisted sectors, and each non-trivial element in $H/\langle g\rangle$ lifts to an element of $\tilde{H}$ that acts non-trivially on the g-invariant untwisted sector, which in turn is part of the spectrum of $\hat{\mathcal{C}}$. Thus, we have an exact sequence

$$1 \to \langle\tilde{g}\rangle \cong \mathbb{Z}_N \to \tilde{H} \xrightarrow{\hat{\rho}} \hat{H} \to 1 \ . \tag{90}$$

The group $\hat{H} \equiv \tilde{H}/\langle\tilde{g}\rangle$ defines a full-fledged symmetry of the orbifold CFT $\hat{\mathcal{C}}$. For the case at hand, both the original theory and the orbifold are K3 sigma models, and thus all of these symmetry groups should be subgroups of M_{24},[§]

$$\hat{H} \subseteq M_{24} \ . \tag{91}$$

This assumption allows us to determine $\hat{H}$ (at least as an abstract group). In fact, the order of $\hat{H}$ is given by

$$|\hat{H}| = \frac{|\tilde{H}|}{N} = |H| = |C_{M_{24}}(g)| \ . \tag{92}$$

The quantum symmetry $Q \equiv \hat{\rho}(\tilde{Q})$ must be in the same M_{24}-conjugacy class as g, since it has the same eigenvalues on the 24-dimensional representation of RR ground states. Since all elements of $\hat{H}$ commute with Q, we can conclude by (92) that

$$\hat{H} = C_{M_{24}}(Q) \cong C_{M_{24}}(g) = H \ . \tag{93}$$

This construction allows us to give a precise interpretation of (88). For each symmetry $h \in H$ in the model $\mathcal{C}$, one chooses a lift $\tilde{h} \in \tilde{H}$, with $\rho(\tilde{h}) = h$ (this amounts to choosing the phases of the twisted twining genera $\phi_{g,h}$). Then the formula for the twining genus of the symmetry $\hat{\rho}(\tilde{h})$ in the orbifold model $\hat{\mathcal{C}}$ takes the form

$$\phi_{e,\hat{\rho}(\tilde{h})} = \frac{1}{o(g)} \sum_{i,j=0}^{o(g)-1} \phi_{g^i,\tilde{h}\tilde{g}^j} \ . \tag{94}$$

After these preparations we can now explain the relabelling phenomenon. While it follows from (93) that $\hat{H}$ and H are isomorphic, they are not canonically isomorphic; in fact, we only have a canonical isomorphism between

$$H/\langle g\rangle \cong \tilde{H}/\langle\tilde{g},\tilde{Q}\rangle \cong \hat{H}/\langle Q\rangle \ , \tag{95}$$

[§] We are assuming here that the relevant K3 sigma model is 'non-exceptional' in the terminology of [40].

but this does not necessarily lift to a canonical isomorphism $\Phi : \hat{H} \to H$, with $\Phi(Q) = g$. Put differently, in general it is not possible to find an isomorphism $\Phi : \hat{H} \to H$, with $\Phi(Q) = g$ such that the following diagram commutes:

$$\begin{tikzcd}
& \tilde{H} \arrow[dl, "\hat{\rho}"'] \arrow[dr, "\rho"] & \\
\hat{H} \arrow[rr, dashed, "\Phi"] \arrow[dr] & & H \arrow[dl] \\
& \tilde{H}/\langle \tilde{g}, \tilde{Q} \rangle &
\end{tikzcd}$$

For example, this will be the case if for any lift $\tilde{h}$ with $\rho(\tilde{h}) = h$, the corresponding symmetry $\hat{\rho}(\tilde{h})$ is not in the same M_{24} conjugacy class as h. In that case, the twining genus obtained by formula (94) does not agree with $\phi_{e,h}$. Whenever this is the case, we shall say that the conjugacy class of h has been *relabelled* in the orbifold theory.

4.2. **An example.** As an explicit example of the relabelling phenomenon let us consider the case where g is in the class 2A of M_{24} (so that $N = o(g) = 2$). Then the group $\tilde{H}$ is a central extension of H by the $\mathbb{Z}_2$ group generated by $\tilde{Q}$. We denote by $\tilde{g}$ the lift of g in $\tilde{H}$, such that $\tilde{g}$ and $\tilde{Q}$ have the following eigenvalues

$\tilde{Q}$	$\tilde{g}$	sector	model
$+1$	$+1$	untwisted	$\mathcal{C}, \hat{\mathcal{C}}$
$+1$	-1	untwisted	$\mathcal{C}$
-1	$+1$	twisted, $q^{\mathbb{Z}}$	$\hat{\mathcal{C}}$
-1	-1	twisted, $q^{\mathbb{Z}+\frac{1}{2}}$	$-$

(96)

As expected from the discussion in the previous section, the group $\tilde{H}/\tilde{Q}$ is isomorphic to the centraliser in M_{24} of an element of class 2A.

Now consider an element $h \in H$ in class 8A, with $h^4 = g$. The trace of h over the 24-dimensional representation of ground states in the original model $\mathcal{C}$ is $+2$. Furthermore, since hg is in the same class, also the trace over hg equals $+2$, from which we conclude that on the ground states of $\mathcal{C}$ we have

$$\mathrm{Tr}_{\mathcal{H}^0_{\tilde{Q}=1,\tilde{g}=1}}(h) = +2 \ , \qquad \mathrm{Tr}_{\mathcal{H}^0_{\tilde{Q}=1,\tilde{g}=-1}}(h) = 0 \ , \tag{97}$$

where $\mathcal{H}^0_{\tilde{Q}=\pm 1,\tilde{g}=\pm 1}$ are the eigenspaces of $\tilde{Q}$ and $\tilde{g}$ at conformal weight $h_L - \frac{1}{4} = 0$. The lifts $\tilde{h}$ and $\tilde{Q}\tilde{h}$ in $\tilde{H}$ are such that $\tilde{h}^4 = (\tilde{Q}\tilde{h})^4 = \tilde{g}$. On dimensional grounds, the twisted sector at $h_L - 1/4 = 0$ must correspond to a certain 8-dimensional irreducible representation of $\tilde{H}$, where the lifts $\tilde{h}$ and $\tilde{Q}\tilde{h}$ have trace ± 2. We notice that, up to a sign, this trace is independent of the choice of the central extension, and is in agreement with the expectation from the twisted twining genus $\phi_{g,h} \equiv \phi_{h^4,h}$. On the ground states in the orbifold theory $\hat{\mathcal{C}}$, the trace of $\tilde{h}$ is now

$$\mathrm{Tr}_{\mathcal{H}^0_{\tilde{Q}=1,\tilde{g}=1}}(\tilde{h}) + \mathrm{Tr}_{\mathcal{H}^0_{\tilde{Q}=-1,\tilde{g}=1}}(\tilde{h}) = 2 \pm 2 \;, \tag{98}$$

and thus there is no choice for $\tilde{h}$ such that the trace is equal to $+2$, as required for an element in class 8A. In fact, the images $\hat{h}$ and $Q\hat{h}$ in $\hat{H} \cong C_{M_{24}}(Q)$ have order 4 and belong to the classes 4A and 4B. In particular, while the pair of commuting elements g, h in the original model generate the cyclic group

$$\langle g, h\rangle = \langle h\rangle \cong \mathbb{Z}_8 \;, \tag{99}$$

both the groups $\langle Q, \hat{h}\rangle$ and $\langle Q, Q\hat{h}\rangle$ correspond to group 12 in our general list. Thus, there cannot exist an isomorphism $\Phi : \hat{H} \to H$ such that $\Phi(\hat{\rho}(\tilde{h})) = h$ or $\Phi(\hat{\rho}(\tilde{Q}\tilde{h})) = h$.

Let us verify the consistency of eq. (94) for this case, see the comments at the beginning of section 4. The twining genera $\phi_{e,\hat{\rho}(\tilde{h})}$ and $\phi_{e,\hat{\rho}(\tilde{Q}\tilde{h})}$ are given by

$$\phi_{e,\hat{\rho}(\tilde{h})}(\tau,z) = \frac{1}{2}(\phi_{e,h}(\tau,z) + \phi_{e,h^5}(\tau,z) + \phi_{h^4,h}(\tau,z) + \phi_{h^4,h^5}(\tau,z)) \;, \tag{100}$$

$$\phi_{e,\hat{\rho}(\tilde{Q}\tilde{h})}(\tau,z) = \frac{1}{2}(\phi_{e,h}(\tau,z) + \phi_{e,h^5}(\tau,z) - \phi_{h^4,h}(\tau,z) - \phi_{h^4,h^5}(\tau,z)) \;. \tag{101}$$

Using the identity

$$\phi_{e,8\mathrm{A}}(\tau,z) = \frac{1}{2}(\phi_{e,4\mathrm{B}}(\tau,z) + \phi_{e,4\mathrm{A}}(\tau,z)) \;, \tag{102}$$

it is easy to verify that

$$\phi_{e,\hat{\rho}(\tilde{h})} = \phi_{e,4\mathrm{B}}, \qquad \phi_{e,\hat{\rho}(\tilde{Q}\tilde{h})} = \phi_{e,4\mathrm{A}} \;, \tag{103}$$

as expected. This example also shows that the consistency of eq. (94) gives, in general, highly non-trivial conditions on the twisted twining genera.

We have verified explicitly that a similar phenomenon also occurs for the orbifold by an element g in class 4B.

4.3. **Computation of a twisted twining genus.** In this section we shall calculate some twisted twining genera directly. In particular, we shall concentrate on some simple cases where our general analysis predicts that they must vanish (because of some obstruction). As we shall see, we can reach the same conclusion from first principles.

Let us consider a K3 σ-model $\mathcal{C}$ whose automorphism group contains two commuting elements g, h of order m and n, respectively, generating the non-cyclic group $G = \langle g, h\rangle$. If these symmetries have a geometric origin, i.e. if they are induced by automorphisms of the K3 target space that fix the holomorphic 2-form, then the group G must be a subgroup of M_{23} with at least five orbits over the 24-dimensional representation, as follows from the Mukai theorem [46]. These conditions are satisfied by the groups 1 and 3 ($\mathbb{Z}_2 \times \mathbb{Z}_2$), groups 17 and 19 ($\mathbb{Z}_2 \times \mathbb{Z}_4$), group 25 ($\mathbb{Z}_4 \times \mathbb{Z}_4$), group 28 ($\mathbb{Z}_2 \times \mathbb{Z}_6$) and group 33 ($\mathbb{Z}_3 \times \mathbb{Z}_3$) of our table 1. In all these cases, the twisted twining genus vanishes, $\phi_{g,h} = 0$, see table 3. In the following we want to verify this independently.

In the general $\mathbb{Z}_n \times \mathbb{Z}_m$ case, the twisted twining genus $\phi_{g,h}$ is expected to be a weak Jacobi form of weight 0 and index 1 under the congruence subgroup

$$\Gamma_{m,n} \equiv \{ \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL(2,\mathbb{Z}) \mid a \equiv 1, b \equiv 0 \mod m,\ c \equiv 0, d \equiv 1 \mod n\}\ . \tag{104}$$

Note that this group is in general smaller than the group $\Gamma_{g,h}$ defined below (24), because we are not using the identifications under conjugation (5). Since both g and h are elements of M_{23}, the multiplier system for $\phi_{g,h}$ must be trivial (since $H^3(M_{23}, U(1)) \cong 0$).

Because of the triviality of the multiplier system, it follows that any modular image $\phi_{g',h'}$ of $\phi_{g,h}$, where $(g', h') = (g, h) \cdot \gamma$ for some $\gamma \in SL(2,\mathbb{Z})$, has a Fourier expansion of the form

$$\phi_{g',h'}(\tau, z) = \sum_{n=0}^{\infty} \sum_{\ell} c_{g',h'}(n, \ell)\, q^{\frac{n}{o(g')}}\, y^{\ell}\ , \tag{105}$$

where $o(g')$ is the order of g'. Let us assume

$$c_{g',h'}(0, \ell) = 0 \quad \forall \ell \in \mathbb{Z}\ , \tag{106}$$

for any modular image $(g', h') = (g, h) \cdot \gamma$; we will prove this below. Then it follows that

$$\phi_{g,h}(\tau, 0) = \sum_{\ell} c_{g,h}(0, \ell) = 0\ . \tag{107}$$

Because of (13), $\phi_{g,h}(\tau, z) = \phi_{g,h}(\tau, -z)$, and we can conclude that $\phi_{g,h}$ has a double zero at $z = 0$ (mod $\mathbb{Z} + \tau\mathbb{Z}$). Since Jacobi forms of index 1 have only two zeroes on each fundamental domain of $\mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ [30], $\phi_{g,h}$ is nowhere else vanishing. Next we recall that $\vartheta_1(\tau, z)^2/\eta(\tau)^2$ is a Jacobi form of weight 0 and index 1 under $SL(2,\mathbb{Z})$ (with a non-trivial multiplier). It has a double zero at $z = 0$ (mod $\mathbb{Z} + \tau\mathbb{Z}$), and is non-vanishing elsewhere, so that

$$F_{g,h}(\tau) = \frac{\eta(\tau)^2 \phi_{g,h}(\tau, z)}{\vartheta_1(\tau, z)^2} \tag{108}$$

is a modular function of weight 0 under $\Gamma_{m,n}$ (with non-trivial multiplier), which is holomorphic in the interior of the upper-half plane $\mathbb{H}_+$. Let us consider the asymptotics of $F_{g,h}$ at the boundary $\Gamma_{m,n}\backslash(\mathbb{Q} \cup \infty)$ of the compactification $\Gamma_{m,n}\backslash\bar{\mathbb{H}}_+$. The boundary is the union of points (cusps) of the form $\gamma(\infty)$, where γ runs through the representatives of the double cosets $\Gamma_{m,n}\backslash SL(2,\mathbb{Z})/\Gamma^\infty$. Here, Γ^∞ is the parabolic subgroup of $SL(2,\mathbb{Z})$ that fixes $\infty \in \bar{\mathbb{H}}_+$ and is generated by $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$. The Jacobi form $\vartheta_1(\tau, z)^2/\eta(\tau)^2$ has the same asymptotic behaviour at each cusp, namely

$$\frac{\vartheta_1(\gamma \cdot (\tau, z))^2}{\eta(\gamma \cdot \tau)^2} \overset{\tau \to \infty}{\sim} q^{1/6}(2 - y - y^{-1}) + O(q^{7/6}) \ , \tag{109}$$

up to a constant coefficient. By (105) and (106), it then follows that

$$F_{g,h}(\gamma \cdot \tau) \sim \frac{\eta(\tau)^2 \phi_{g',h'}(\tau, z)}{\vartheta_1(\tau, z)^2} \overset{\tau \to \infty}{\sim} O(q^{\frac{1}{o(g')} - \frac{1}{6}}) \ , \tag{110}$$

where $(g', h') = (g, h)\gamma$ and $o(g')$ is the order of g'. For all the groups we are interested in, we have $o(g') \leq 6$, and the inequality is strict for at least one g'. It follows that $F_{g,h}$ has no poles and at least one zero at the boundary of $\Gamma_{m,n}\backslash\bar{\mathbb{H}}_+$. Since it is holomorphic in the interior, it must therefore vanish identically, and we conclude that

$$\phi_{g,h}(\tau, z) = 0 \ , \tag{111}$$

as predicted by our results.

It therefore only remains to prove (106). The coefficient $c_{g,h}(0, \ell)$ corresponds to the trace of h (or, more generally, of the lift $\tilde{h}$ to a central extension of the group $\langle g, h\rangle$) on the RR g-twisted states with conformal weight $h_L = h_R = 1/4$ and weight ℓ under the $\mathfrak{su}(2)_L$ subalgebra of the left-moving $\mathcal{N} = 4$ algebra. The g-twisted ground states are g-invariant (the conformal weight satisfies $h_L - 1/4 \in \mathbb{Z}$), so they belong to the spectrum of the orbifold theory $\mathcal{C}/\langle g\rangle$.

Any sigma-model whose target space is a K3 manifold X contains 24 RR ground states corresponding to the harmonic forms on X. Thus, the real vector space spanned by these states can be identified with the real cohomology $H^*(X, \mathbb{R})$ on X. The orbifold model $\hat{\mathcal{C}} = \mathcal{C}/\langle g\rangle$ corresponds to a non-linear sigma-model on the geometric orbifold $\hat{X} = X/\langle g\rangle$, which is a singular K3 surface. In particular, for each point of X that is fixed by some non-trivial subgroup $\langle g^r\rangle \subseteq \langle g\rangle$, the orbifold $\hat{X}$ has a singularity of type A_{n-1}, where n

is the order of g^r. By blowing up all these singularities, one obtains again a smooth K3 manifold.

The RR ground states in the untwisted sector of $\hat{\mathcal{C}}$ are obtained by projecting onto the g-invariant subspace of $H^*(X,\mathbb{R})$, while the ground states in the twisted sectors are the Poincaré duals of the cycles corresponding to the exceptional divisors in the blow-up of $\hat{X}$. More precisely, the resolution of each A_{n-1} singularity of $\hat{\mathcal{C}}$ gives rise to $n-1$ rational curves $\mathbb{P}^1$, representing elements in the homology of the blow-up. The cohomology classes dual to these cycles span an $(n-1)$-dimensional subspace of RR ground states for $\hat{\mathcal{C}}$, one in each g^{ir} twisted sector, for $i = 1, \ldots, n-1$. Thus, we arrive at the usual statement that the ground states of the g^k-twisted sector are in one to one correspondence with the g^k-fixed points of the target space.

Any other symplectic automorphism h of X that commutes with g acts as a permutation on the g^r-fixed points. This action induces a permutation on the singularities of $\hat{X}$, and therefore on the twisted RR ground states dual to the exceptional cycles.[¶] Therefore, the trace of h over the g-twisted sector only gets a non-zero contribution from the singularities of $\hat{X}$ that are fixed by h, i.e. only from the points of X that are fixed by both g and h. It is known (see, for example Proposition 1.5 of [46]) that a finite group of symplectic automorphisms of a K3 manifold X that fixes at least one point must be a subgroup of $SL(2,\mathbb{C})$. On the other hand, all finite abelian subgroups of $SL(2,\mathbb{C})$ are cyclic. Thus we conclude that if $\langle g, h\rangle$ is abelian but not cyclic, the trace of h over the g-twisted ground fields is 0 and (106) follows.

Our results also agree with the analysis of [47], where it was shown that the twisted twining genus $\phi_{g,h}$ for a pair of commuting symplectic automorphisms g, h of a K3 manifold X is given by a sum of contributions corresponding to the points fixed by both g and h. If the abelian group $\langle g, h\rangle$ is not cyclic, then there are no fixed points and $\phi_{g,h} = 0$.

5. CONCLUSIONS

5.1. **Summary.** Inspired by the generalised Monstrous Moonshine idea of Norton [14] we have in this paper established 'generalised Mathieu Moonshine' for the elliptic genus of K3. More specifically, we have found, for each commuting pair $(g,h) \in M_{24}$, explicit expressions for the twisted twining genera $\phi_{g,h} : \mathbb{H}_+ \times \mathbb{C} \to \mathbb{C}$, and we have verified that these functions satisfy conditions (A), (B), (D) of section 2.1, and given convincing evidence that condition (C) is also met. In particular, the twisted twining genera $\phi_{g,h}(\tau, z)$ are weak Jacobi forms of weight 0 and index 1 for certain subgroups $\Gamma_{g,h} \subset SL(2, \mathbb{Z})$ with a multiplier system $\chi_{g,h} : \Gamma_{g,h} \to U(1)$.

[¶] More precisely, one should choose a lift $\tilde{h}$ of h to a central extension of the group of symmetries of $\mathcal{C}$; then, $\tilde{h}$ acts on the g-twisted sector by a permutation times an overall phase that depends on the particular lift. Since the phase is not important for our argument, we will neglect this subtlety.

One of the key insights of our work is that these multiplier phases are all determined in terms of a class $[\alpha] \in H^3(M_{24}, U(1))$ via a formula (see eq. (39)) that was first derived by Dijkgraaf and Witten in the context of holomorphic orbifolds [25]. We have also shown that the twisted twining genera $\phi_{g,h}$ are compatible with a decomposition of the g-twisted sector into (projective) representations of the centraliser $C_{M_{24}}(g)$, up to the first 500 levels. The particular central extension of $C_{M_{24}}(g)$ associated with this projective representation is also determined by the cohomology class $[\alpha] \in H^3(M_{24}, U(1))$.

As it turned out, many of the twisted twining genera vanish, and in most cases this follows from the structure of the class $[\alpha] \in H^3(M_{24}, U(1))$. While these sorts of cohomological obstructions should also arise in the context of other holomorphic orbifolds (in particular in Monstrous Moonshine), our results provide, to our knowledege, the first example where they have been explicitly verified. We have also confirmed the vanishing of some of these twisted twining genera independently, using geometrical arguments.

5.2. **Open problems and future work.** The elliptic genus of K3 is closely related to the physics of 1/4 BPS-dyons in $\mathcal{N} = 4$ string theory. The generating function of elliptic genera of symmetric products of K3's is the famous Igusa cusp form Φ_{10}, whose inverse is the partition function of $\mathcal{N} = 4$ dyons [48, 49]. This fact lies at the heart of the recent progress in understanding wall-crossing of multi-centered BPS-states in $\mathcal{N} = 4$ string theory using mock modular forms [50]. It is therefore natural to wonder about the corresponding physical interpretation of the twisted twining genera $\phi_{g,h}$. In the special case of a trivial twist $g = e$, it has been shown that for some elements h the twining genera $\phi_{e,h}$ correspond to BPS-indices in CHL-orbifolds [6, 51, 52, 53]. We may therefore expect that the twisted twining genera $\phi_{g,h}$ should be related to the counting of 'twisted dyons' in CHL-models. Indeed for some pairs (g, h) we have verified this by showing that the twisted CHL-indices of Sen [47] are compatible with our $\phi_{g,h}$. It would be interesting to determine more generally whether $\phi_{g,h}$ have a physical interpretation in terms of CHL-models or some generalisation thereof.

In Borcherds' proof of the Monstrous Moonshine conjecture he introduced a new class of infinite-dimensional (super-)Lie algebras that he called generalised Kac-Moody algebras

(GKM) [3]. The key idea was that the multiplicative lift of the modular J-function could be interpreted as the denominator formula for a specific GKM, now commonly called the Monster Lie algebra, whose root system carries an action of the Monster group $\mathbb{M}$. The generalised moonshine ideas of Norton [14] suggest that similar GKMs should exist for each class $[g] \in \mathbb{M}$ [20, 21, 54]. In the context of Mathieu Moonshine the role of generalised Kac-Moody algebras has so far not been understood. Although there is a GKM associated with the elliptic genus of K3 [55], this algebra does not seem to carry any natural action of M_{24} due to the fact that its denominator formula is $1/\sqrt{\Phi_{10}}$ rather than $1/\Phi_{10}$. For some conjugacy classes $[g] \in M_{24}$ the associated second-quantised twining genera Φ_g also give rise to denominator formulas of GKMs [56], which should presumably be identified with the wall-crossing algebras found in CHL-models [57, 58, 59, 60, 51]. Although these observations are very suggestive, the precise role of the GKMs for Mathieu Moonshine remains to be understood.

A crucial point in our analysis was that the multiplier phases are controlled by a class $[\alpha] \in H^3(M_{24}, U(1))$, from which also the various obstructions could be read off. It follows from the work of [25, 37] that similarly a cohomology class in $H^3(\mathbb{M}, U(1))$ should underly generalised Monstrous Moonshine, and it would be very interesting to see whether this point of view may lead to new insights. In particular, some of Norton's generalised Moonshine functions $f(g, h; \tau)$ are known to vanish, and it would be natural to expect that this is due to some cohomological obstructions similar to those we have found in this paper.[‖] Some related ideas were already put forward some time ago by Mason [27], but very little has been done explicitly, mainly because the group $H^3(\mathbb{M}, U(1))$ seems to be poorly understood.

In a similar vein, it would also be interesting to investigate the generalised versions of the recently discovered Umbral Moonshine observations [61], of which the M_{24}/K3-moonshine is a special case. In particular, one might expect that there is a relation between the Rademacher summability condition of [12] and the cohomological obstructions we have described here.

The fact that there is a class in $H^3(M_{24}, U(1))$ determining the properties of the twisted twining genera $\phi_{g,h}$ represents strong evidence for the idea that a holomorphic VOA $\mathcal{H}$ underlies Mathieu Moonshine. Indeed, the original motivation for suspecting the relevance of the cohomology group $H^3(M_{24}, U(1))$ was based on the formal analogy with holomorphic orbifolds [25, 37]. In a sense we are therefore in a similar situation now as for Monstrous

---

[‖] We thank Terry Gannon for suggestions along these lines, see also [10].

Moonshine before the discovery of the Monster VOA $V^\natural$ [2]. However, the story appears to be more subtle since the natural expectation that $\mathcal{H}$ would arise as a superconformal σ-model on K3 does not hold [13]. On the other hand, this is perhaps not too surprising, given the fact that the modular J-function corresponds to the *full* partition function of a CFT, while the elliptic genus of K3 only receives contribution from a *subset* of the physical states of the $\mathcal{N} = (4,4)$ superconformal theory on K3. Hence it is tempting to speculate that $\mathcal{H}$ should correspond to something like the algebra of BPS-states of string theory on K3 (in the sense of Harvey and Moore [62, 63]). In particular, one might therefore hope that $\mathcal{H}$ can be constructed using some kind of topological sigma model, e.g. the 'half-twisted' topological σ-model on K3 [64]. Mathematically, this sigma model (or rather its large radius limit) can be viewed as a bundle of VOAs known as the chiral de Rham complex, Ω^{ch}_X [65], and in [66] it was shown that the elliptic genus of K3 can be obtained by taking the graded trace over the corresponding cohomology $H^*(\Omega^{ch}_X)$. It is therefore tempting to speculate that one may be able to construct an action of M_{24} on the cohomology of Ω^{ch}_X, at least for some choice of K3 surface X.

We hope to return to these and related issues in future work.

Acknowledgements

We are indebted to Terry Gannon for the suggestion that the 3rd cohomology of M_{24} should control the modular properties of the twisted twining genera, as well as for many useful explanations and directions to the relevant literature. We are furthermore grateful to Mathieu Dutour and Graham Ellis for helpful correspondence on using the computer package `HAP` for calculating the cohomology of finite groups. We also thank Nils Carqueville, Miranda Cheng, Jeff Harvey, Stefan Hohenegger, Axel Kleinschmidt, Sameer Murthy, Daniel Roggenkamp, Ashoke Sen and Don Zagier for useful discussions, as well as the anonymous referee for many useful suggestions that considerably improved the exposition of the paper. D.P. would like to thank the Albert Einstein Institute in Golm for hospitality while part of this work was carried out. The work of M.R.G. is partially supported by the Swiss National Science Foundation, and the visit of Henrik Ronellenfitsch at ETH was supported by the Pauli Center.

Appendix A. Details on the unobstructed twisted twining genera

In this appendix, following the example of section 3.4, we will determine the twisted twining genera $\phi_{g,h}$ for the groups 13, 23, 24, 33 and 34 in Table 1. The genus $\phi_{\mathrm{2B},\mathrm{8A}_{1,2}}$ for group

27 was obtained in section 3.4, while for all the other groups $\phi_{g,h}$ vanishes due to some obstruction.

A.1. **The characters $\phi_{2\mathrm{B},4\mathrm{A}_2}$ (group 13) $\phi_{4\mathrm{B},4\mathrm{A}_3}$ (group 23) and $\phi_{4\mathrm{B},4\mathrm{A}_4}$ (group 24).** In this section we will consider the twisted twining genera $\phi_{g,h}$ for groups 13, 23 and 24; as we will see, it turns out that these three characters have exactly the same modular properties. For group 13 g is in class 2B and h in class 4A, and we can choose

$$\begin{aligned} g &= (1,10)(2,14)(3,8)(4,16)(5,15)(6,12)(7,21)(9,18)(11,13)(17,20)(19,23)(22,24) \ , \\ h &= (1,2)(3,18)(4,7,15,17)(5,20,16,21)(6,19,24,11)(8,9)(10,14)(12,23,22,13) \ . \end{aligned} \tag{112}$$

For the groups 27 and 28, g is in class 4B and h in class 4A and we can choose

$$g = (3,8)(4,21,15,20)(5,17,16,7)(6,19,24,11)(9,18)(12,23,22,13) \ , \tag{113}$$

for both groups (from now on, we drop the trivial cycles). For group 23 we can take

$$h = (1,10)(2,14)(3,9)(4,11,5,13)(6,17,12,21)(7,22,20,24)(8,18)(15,19,16,23) \ . \tag{114}$$

and for group 24

$$h = (1,2,10,14)(3,9,8,18)(4,5,15,16)(6,13)(7,21,17,20)(11,22)(12,19)(23,24) \ , \tag{115}$$

In all the three cases we have the relations

$$(k^{-1}gk, k^{-1}ghk) = (g,h) \ , \qquad (r^{-1}gh^{-2}r, r^{-1}hr) = (g,h) \ , \tag{116}$$

where, for group 13

$$k = (1,9,2,3)(6,13,22,19)(7,21)(8,10,18,14)(11,24,23,12)(17,20) \ , \tag{117}$$

$$r = (3,8)(4,11,5,13)(6,20,12,7)(9,18)(15,19,16,23)(17,24,21,22) \ , \tag{118}$$

for group 23

$$k = (1,2,10,14)(3,9,8,18)(5,16)(6,11,24,19)(7,17)(12,23,22,13) \ , \tag{119}$$

$$r = (1,2)(3,8)(6,12)(7,20)(9,18)(10,14)(17,21)(22,24) \ , \tag{120}$$

and for group 24

$$k = (3,9)(4,12,5,6)(7,11,20,13)(8,18)(15,22,16,24)(17,19,21,23) \ , \tag{121}$$

$$r = (1,3)(2,9)(4,20)(5,7)(8,10)(14,18)(15,21)(16,17) \ . \tag{122}$$

Using the explicit knowledge of the 3-cocycle α we can derive the modular properties of the twisted twining genus $\phi_{g,h}$, including the multiplier system. It turns out that in all these three cases $\phi_{g,h}$ is invariant under $\Gamma_0(2)$ with the same multiplier

$$\phi_{g,h}(\tau+1) = c_g(g,h)\frac{c_g(gh,k)}{c_g(k,h)}\phi_{g,h}(\tau) = i\phi_{g,h}(\tau) \ , \tag{123}$$

$$\begin{aligned}\phi_{g,h}(\frac{\tau}{2\tau+1}) &= \frac{1}{c_h(h,h^{-1}g)c_h(h,h^{-2}g)}\frac{c_h(h^{-2}g,r)}{c_h(r,g)}\phi_{g,h}(\tau) \\ &= -i\phi_{g,h}(\tau) \ . \end{aligned}\tag{124}$$

By arguments similar to the ones in section 4.3, $\phi_{g,h}(\tau,z)$ has only a double zero at $z=0$ (mod $\mathbb{Z}+\tau\mathbb{Z}$). This implies that $\phi_{g,h}$ can be expressed as

$$\phi_{g,h}(\tau,z) = \frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2}F(\tau) \tag{125}$$

for some $\Gamma_0(2)$-invariant function $F(\tau)$ that is holomorphic in $\mathbb{H}_+$. The group $\Gamma_0(2)$ has two cusps at ∞ and 0. To proceed we study the asymptotic behavior at infinity

$$\phi_{g,h}(\tau,z) = A_\infty\, q^{1/4}(2-y-y^{-1}) + \cdots \tag{126}$$

$$\frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,0)^2} = \frac{1}{4}\,(2-y-y^{-1}) + \cdots \ , \tag{127}$$

which implies that $F(\tau) \sim 4A_\infty\, q^{1/4} + \cdots$ has a zero at $\tau\to\infty$. The behavior at $\tau=0$ is

$$\phi_{g,h}(\gamma_0(\tau,z)) \sim \phi_{h,g^{-1}}(\tau,z) = A_0\, q^{1/8}\,(2-y-y^{-1}) + \cdots \tag{128}$$

$$\frac{\vartheta_1(\tau,z)^2}{\vartheta_4(\tau,0)^2} = q^{1/4}\,(2-y-y^{-1}) + \cdots \ , \tag{129}$$

implying that $F(\gamma_0\cdot\tau) \sim A_0\, q^{-1/8} + \cdots$ has a pole at 0. A function with the correct modular properties and behaviour at the cusps is

$$F(\tau) = 4A_\infty\,\frac{\eta(2\tau)^6}{\eta(\tau)^6} \ , \tag{130}$$

so that

$$\phi_{g,h}(\tau,z) = 4A_\infty\frac{\eta(2\tau)^6}{\eta(\tau)^6}\frac{\vartheta_1(\tau,z)^2}{\vartheta_2(\tau,z)^2} = A_\infty\frac{\eta(2\tau)^2}{\eta(\tau)^4}\vartheta_1(\tau,z)^2 \ . \tag{131}$$

The constants A_∞ for the three cases are determined (up to the phase) by ensuring a decomposition into projective characters of $C_{M_{24}}(g)$. In particular, $A_\infty = 4$ for group 13 and $A_\infty = 2\sqrt{2}$ for groups 23 and 24.

A.2. **The cases $\phi_{3\mathrm{A},3\mathrm{A}_3}$ (group 33) and $\phi_{3\mathrm{A},3\mathrm{B}_1}$ (group 34).** In this section we show that the unobstructed twisted twining genera $\phi_{3\mathrm{A},3\mathrm{A}_3}$ and $\phi_{3\mathrm{A},3\mathrm{B}_1}$ must vanish by modular arguments.

Let us consider first the group $\langle g,h\rangle = \langle 3\mathrm{A}, 3\mathrm{B}_1\rangle$ (type 34), generated by

$$g = (2,23,11)(3,20,10)(5,14,9)(6,16,13)(7,19,22)(12,24,18) \tag{132}$$

in class 3A and

$$h = (1,15,17)(2,19,16)(3,18,5)(4,21,8)(6,11,7)(9,10,24)(12,14,20)(13,23,22) \tag{133}$$

in class 3B. The following conjugation relation holds

$$(k^{-1}gk, k^{-1}ghk) = (g,h)\ , \tag{134}$$

where

$$k = (2,7,16)(3,20,10)(4,21,8)(5,9,14)(6,11,22)(13,23,19)\ . \tag{135}$$

The modular properties of the associated twisted twining genus are

$$\phi_{g,h}(\tau+1) = c_g(g,h)\frac{c_g(gh,k)}{c_g(k,h)}\phi_{g,h}(\tau) = e^{\frac{4\pi i}{3}}\phi_{g,h}(\tau)\ , \tag{136}$$

and

$$\phi_{g,h}\left(\frac{\tau}{-3\tau+1}\right) = \prod_{i=0}^{2} c_h(h, h^i g^{-1})\phi_{g,h}(\tau) = e^{\frac{4\pi i}{3}}\phi_{g,h}(\tau)\ , \tag{137}$$

where we have used the explicit form for the multiplier phases as determined in terms of the 3-cocycle $\alpha \in H^3(M_{24}, U(1))$. We conclude that, up to the multiplier, $\phi_{g,h}$ is invariant under $\Gamma_0(3)$. Furthermore, as in the previous subsection and in section 4.3, for each fixed $\tau \in \mathbb{H}_+$, $\phi_{g,h}(\tau,z)$ has only a double zero at $z=0$ (mod $\mathbb{Z}+\tau\mathbb{Z}$). Since $\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^2}$ is a weak Jacobi form of weight 0 and index 1 with non-trivial multiplier under $SL(2,\mathbb{Z})$ and only a double zero at $z=0$, we have

$$\phi_{g,h}(\tau,z) = \frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^2}F_{g,h}(\tau) \tag{138}$$

for some function $F_{g,h}(\tau)$ that is $\Gamma_0(3)$-invariant (up to a multiplier). The asymptotics for $\tau \to \infty$ is

$$\phi_{g,h}(\tau,z) \sim A_\infty\, q^{\frac{2}{3}} + \cdots\ , \tag{139}$$

for some (possibly vanishing) constant A_∞, while the asymptotic behavior at 0 is given by

$$\phi_{h,g}(\tau,z) \sim A_0\, q^{\frac{2}{9}} + \cdots\ . \tag{140}$$

Since both at ∞ and 0 we have

$$\frac{\vartheta_1(\tau,z)^2}{\eta(\tau)^2} \sim q^{1/6}(2-y-y^{-1})+\cdots \ , \tag{141}$$

we deduce that $F_{g,h}$ has a zero at both 0 and ∞ and no poles; hence it must vanish. We therefore conclude

$$\phi_{3\mathrm{A},3\mathrm{B}_1}(\tau,z)=0 \ , \tag{142}$$

as claimed.

The $(3\mathrm{A},3\mathrm{A}_3)$-case (group 33) is analogous. Here, the group is generated by

$$g=(2,23,11)(3,20,10)(5,14,9)(6,16,13)(7,19,22)(12,24,18) \tag{143}$$

and

$$h=(2,22,13)(4,21,8)(5,14,9)(6,23,7)(11,19,16)(12,18,24) \ , \tag{144}$$

and we have the relations

$$(k^{-1}gk,k^{-1}ghk)=(g,h) \ , \qquad (r^{-1}hr,r^{-1}g^{-1}r)=(g,h) \tag{145}$$

where

$$k=(1,17,15)(3,9,24)(5,18,20)(6,16,13)(7,22,19)(10,14,12) \ , \tag{146}$$

$$r=(3,4,10,21)(5,18)(6,16,19,7)(8,20)(9,24,14,12)(11,22,23,13) \ . \tag{147}$$

The modular properties of $\phi_{g,h}$ are

$$\phi_{g,h}(\tau+1)=c_g(g,h)\,\frac{c_g(gh,k)}{c_g(k,h)}\,\phi_{g,h}(\tau)=e^{\frac{4\pi i}{3}}\,\phi_{g,h}(\tau) \ , \tag{148}$$

$$\phi_{g,h}(-1/\tau)=\frac{1}{c_h(g,g^{-1})}\frac{c_h(g^{-1},r)}{c_h(r,h)}\phi_{g,h}(\tau)=\phi_{g,h}(\tau) \ . \tag{149}$$

Thus $\phi_{g,h}$ is invariant (up to a multiplier) under $SL(2,\mathbb{Z})$, and $\phi_{g,h}\sim A\,q^{2/3}$ at ∞, so that

$$F_{3\mathrm{A},3\mathrm{A}_3}(\tau)\equiv\phi_{g,h}(\tau,z)\frac{\eta(\tau)^2}{\vartheta_1(\tau,z)^2}\sim A\,q^{1/2}+\cdots \ . \tag{150}$$

Thus, $F_{3\mathrm{A},3\mathrm{A}_3}$ has a zero and no poles and therefore must vanish, thus leading to

$$\phi_{3\mathrm{A},3\mathrm{A}_3}(\tau,z)=0 \ . \tag{151}$$

Appendix B. Some group cohomology

In this section, we will review the basic definitions and properties of group cohomology, see for example [43] for an introduction to the subject.

In general, group cohomology is defined in terms of a finite group G and a G-module A, i.e. an abelian group with an action of G satisfying certain compatibility properties. For our purposes, it is sufficient to consider $A = U(1)$ with the trivial action of G. An n-cochain ψ (with $n \geq 0$) for G with values in $U(1)$ is simply a function from $G \times \ldots \times G$ (n times) to $U(1)$; a 0-cochain is just an element of $U(1)$. On the space $C^n(G, U(1))$ of n-cochains one can define a *coboundary* operator $\partial_n : C^n(G, U(1)) \to C^{n+1}(G, U(1))$ by

$$\begin{aligned}\partial_n\psi\,(g_1, \ldots, g_{n+1}) &= \psi(g_2, \ldots, g_{n+1}) \\ &\times \prod_{i=1}^{n} \psi(g_1, \ldots, g_{i-1}, g_i g_{i+1}, g_{i+2}, \ldots, g_{n+1})^{(-1)^i}\, \psi(g_1, \ldots, g_n)^{(-1)^{n+1}} \ . \quad (152)\end{aligned}$$

The cochains in the kernel of ∂_n are called n-cocycles (or co-closed n-cochains), while the cochains in the image of ∂_{n-1} are called n-coboundaries. The coboundary operator satisfies $\partial_{n+1} \circ \partial_n = 1$ (the trivial element of $U(1)$), so that we can define the cohomology, as usual, as the quotient of the space of cocycles modulo coboundaries

$$H^n(G, U(1)) = \frac{\ker \partial_n}{\mathrm{Im}\partial_{n-1}} \ , \tag{153}$$

where $n > 0$, and we use the convention that $H^0(G, U(1)) = U(1)$, and that every 0-cochain is coclosed, ie. $\partial_0 = 1$.

In particular, for a 1-cochain γ, the condition $\partial_1\gamma = 1$ is simply $\gamma(g)\gamma(h) = \gamma(gh)$ for all $g, h \in G$, so that $H^1(G, U(1))$ is just the group of homomorphism from G to $U(1)$. A 2-cochain $\beta : G \times G \to U(1)$ is co-closed (and hence defines a cocycle) provided it satisfies

$$\beta(g_1, g_2 g_3)\, \beta(g_2, g_3) = \beta(g_1 g_2, g_3)\, \beta(g_1, g_2) \tag{154}$$

for $g_1, g_2, g_3 \in G$. The second cohomology $H^2(G, U(1))$ then consists of the co-closed 2-cochains, modulo the ambiguity

$$\beta(g_1, g_2) \to \beta(g_1, g_2) \frac{\gamma(g_1)\gamma(g_2)}{\gamma(g_1 g_2)} \ , \tag{155}$$

where γ is an arbitrary 1-cochain, i.e. an arbitrary function $\gamma : G \to U(1)$. The second cohomology of a group G classifies the inequivalent projective representations of G, see appendix C. A 3-cochain α,

$$\alpha : G \times G \times G \to U(1) \tag{156}$$

is closed provided it satisfies

$$\alpha(g_1,g_2,g_3)\,\alpha(g_1,g_2g_3,g_4)\,\alpha(g_2,g_3,g_4)=\alpha(g_1g_2,g_3,g_4)\,\alpha(g_1,g_2,g_3g_4)\ . \tag{157}$$

In the cohomology group $H^3(G,U(1))$ the 3-cocycles are then identified modulo

$$\alpha(g_1,g_2,g_3)\to\alpha(g_1,g_2,g_3)\,\frac{\beta(g_1,g_2g_3)\beta(g_2,g_3)}{\beta(g_1g_2,g_3)\beta(g_1,g_2)}\ . \tag{158}$$

Note that the multiplying factor is trivial if β is closed, i.e. if it satisfies the 2-cocycle condition (154). We shall always work with normalised cocycles, i.e. we shall assume that

$$\alpha(e,g_1,g_2)=\alpha(g_1,e,g_2)=\alpha(g_1,g_2,e)=1 \tag{159}$$

for all $g_1,g_2\in G$, where e denotes the identity element of G.

Given a 3-cocycle α, we can define, for any $h\in G$, a 2-cochain $c_h:G\times G\to U(1)$ via

$$c_h(g_1,g_2)=\frac{\alpha(h,g_1,g_2)\,\alpha(g_1,g_2,(g_1g_2)^{-1}h(g_1g_2))}{\alpha(g_1,g_1^{-1}hg_1,g_2)}\ . \tag{160}$$

It is shown in [25] that c_h defines a 2-cocycle of the centraliser $C_G(h)\subset G$ (i.e. the subgroup of all elements g_1,g_2 which commute with h). When $g_1,g_2\in C_G(h)$, we have the simplified expression

$$c_h(g_1,g_2)=\frac{\alpha(h,g_1,g_2)\,\alpha(g_1,g_2,h)}{\alpha(g_1,h,g_2)}\ ,\qquad g_1,g_2\in C_G(h)\ . \tag{161}$$

Under the 'gauge transformation' (158), c_h transforms as

$$c_h(g_1,g_2)\to c_h(g_1,g_2)\frac{\gamma_h(g_1)\gamma_h(g_2)}{\gamma_h(g_1g_2)}\ ,\qquad g_1,g_2\in C_G(h)\ , \tag{162}$$

where we defined the 1-cochain γ_h by

$$\gamma_h(g)\equiv\frac{\beta(g,h)}{\beta(h,g)}\ . \tag{163}$$

This is indeed of the form (155), and hence, for all $h\in G$, c_h defines a map

$$c_h\ :\ H^3(G,U(1))\ \to H^2(C_G(h),U(1))\ . \tag{164}$$

Appendix C. Projective representations of finite groups

This section follows [37, 67]. A projective representation is a map $\rho:G\to\mathrm{End}(V)$ from a group G to the endomorphism group of some complex vector space V satisfying

$$\rho(g)\,\rho(h)=\beta(g,h)\,\rho(gh)\ ,\quad \beta(g,h)\in U(1)\ . \tag{165}$$

It follows from the associativity of the group multiplication that the phase $\beta(g,h)$ satisfies the 2-cocycle condition

$$\beta(g,h)\,\beta(gh,k)=\beta(h,k)\,\beta(g,hk)\ . \tag{166}$$

There is the freedom of rescaling the maps $\rho(g)$ as

$$\rho(g) \mapsto \gamma(g)\rho(g) \ , \quad \gamma(g) \in U(1) \ . \tag{167}$$

For the 2-cocylce β this leads to the rescaling by a coboundary

$$\beta(g,h) \to \beta(g,h)\,\gamma(gh)\,\gamma(g)^{-1}\,\gamma(h)^{-1} \ . \tag{168}$$

In particular, one can always choose a rescaling such that $\rho(e)$ is the identity matrix in $\mathrm{End}(V)$; with this choice, the cocycle β is normalised. Two projective representations whose 2-cocycles differ only by a coboundary are called projectively equivalent, since their representation matrices are related by a rescaling. Therefore, the inequivalent projective representations of G are captured by the second group cohomology $H^2(G,U(1))$.

As for genuine linear representations, one may define the character of a projective representation as the trace

$$\chi(g) = \ \mathrm{Tr}_V(\rho(g)) \ . \tag{169}$$

Due to the modified composition law, projective characters are in general not class functions, but differ by a phase on different representatives of one conjugacy class. However, it is always possible to choose a cocycle representative such that the characters are indeed class functions.

Assuming that $gh = hg$, we have, using the projective composition law,

$$\chi(g) = \chi(h^{-1}gh) = \frac{\beta(gh,h^{-1})}{\beta(h^{-1},gh)}\,\chi(g) \ . \tag{170}$$

Using the cocycle condition, it is easy to see that this condition on the characters is equivalent to the obstuction of the first kind (14). Also, the obstruction does not depend on the specific cocycle representative $\beta(g,h)$ or the class representative g. Classes whose projective characters vanish are called β-irregular. It may be shown that to each cocycle $\beta(g,h)$, there exist exactly as many linearly inequivalent irreducible projective representations as there are β-regular conjugacy classes.

Two irreducible characters belonging to representations with the same cocycle $\beta(g,h)$ satisfy an orthogonality relation of the form

$$\sum_{[g]} |K_g|^{-1}\,\chi(g)^*\,\tilde\chi(g) = \begin{cases} 1 & \chi = \tilde\chi \\ 0 & \text{otherwise,} \end{cases} \tag{171}$$

where the sum is taken over a set of (β-regular) class representatives of G, and $|K_g|$ is the size of the conjugacy class of g.

There is a natural connection between projective representations and central extensions of a group G. We say that $\tilde{G}$ is a central extention of G if there is an abelian subgroup $A \subset Z(\tilde{G})$ of the center $Z(\tilde{G})$ of $\tilde{G}$ such that the short sequence

$$0 \to A \to \tilde{G} \to G \to 0 \tag{172}$$

is exact, or equivalently that $G = \tilde{G}/A$. The simplest central extension is of course $\tilde{G} = A \times G$, but this is in general not the only possibility. It can be shown that the non-isomorphic central extensions of G by A are also classified by $H^2(G, A)$. Each set of projectively inequivalent projective representations of G corresponds to a set of genuine representations of some extension $\tilde{G}$.

In some sense there exists a maximal central extension S for each G, the Schur cover or 'Darstellungsgruppe'. It is characterised by the property that any projective representation of G corresponds to a genuine representation of S. The Schur cover is, in general, not unique, unless G is a perfect group, i.e. it coincides with the commutator subgroup. Otherwise, the Schur covers are related by isoclinism.

C.1. **Central extension and orbifolds.** Let $\mathcal{C}$ be a K3 sigma-model and suppose that its automorphism group contains an element g such that the orbifold of $\mathcal{C}$ by g, $\hat{\mathcal{C}} = \mathcal{C}/\langle g\rangle$ is consistent. In this subsection, we will show that all projective representations of $H \equiv C_{M_{24}}(g)$ on the g^r-twisted sectors are equivalent to genuine representations of a central extension $\tilde{H}$ of the form described in section 4.1, eq. (89).

By (54) and (62), the level-matching condition is satisfied if and only if the restriction of the class $[\alpha] \in H^3(M_{24}, U(1))$ to $H^3(\langle g\rangle, U(1))$ is trivial. Each g^r-twisted sector carries a, in general projective, representation ρ_{g^r} of $H \equiv C_{M_{24}}(g)$, with underlying 2-cocycle c_{g^r} given by (39). The various cocycles c_{g^r} are related to one another by the identity

$$c_{g^r}(h,k) = \frac{f_{g,r}(h) f_{g,r}(k)}{f_{g,r}(hk)}\, c_g(h,k)^r \ , \qquad h, k \in C(g) \ , \tag{173}$$

where

$$f_{g,r}(h) = \prod_{i=1}^{r-1} c_h(g, g^i) \ . \tag{174}$$

Here we have used the definition (39) of c_g and applied repeatedly the condition that the 3-cocycle α is closed. Thanks to the level-matching condition, we can choose the representative cocycle α to be identically 1 when restricted to $\langle g\rangle$, so that $f_{g,r}(g^i) = 1$ for all i. Furthermore, by changing α by a coboundary $\partial\beta$ as in (158), the functions $f_{g,r}(h)$ transform as

$$f_{g,r}(h) \to f_{g,r}(h)\, \frac{\beta(g^r,h)\beta(h,g)^r}{\beta(h,g^r)\beta(g,h)^r}\ . \tag{175}$$

Thus, we can choose β in such a way that $f_{g,r}(h) = 1$ for all $h \in C(g)$, so that

$$c_{g^r}(h,k) = c_g(h,k)^r\ , \qquad h,k \in C(g)\ . \tag{176}$$

In particular, since $c_e(h,k) = 1$, $c_g(h,k)$ is always an N-th root of unity, where $N = o(g)$.

APPENDIX D. CENTRALISERS $C_{M_{24}}(g)$ AND (PROJECTIVE) CHARACTER TABLES

This section describes the projective character tables of the centraliser $H \equiv C_{M_{24}}(g)$ for each conjugacy class of M_{24}, corresponding to the projective equivalence class determined by the 2-cocycle c_g. The procedure to compute these tables is as follows.

Let Schur(H) denote a Schur cover of H, i.e. a central extension of H fitting into the exact sequence

$$1 \to M(H) \to \mathrm{Schur}(H) \to H \to 1\ , \tag{177}$$

where $M(H) = H_2(H,\mathbb{Z}) = (H^2(H,U(1)))^*$ is the Schur multiplier. The Schur cover Schur(H) and its character table can be easily computed (we used `GAP` [41] for this). Any irreducible projective representation ρ of H is equivalent to a genuine irreducible representation $\tilde\rho$ of Schur(H) and vice versa. Thus, one can associate a class of $H^2(H,U(1))$ to each irreducible representation of Schur(H). The projective character table we are interested in is obtained from the one of Schur(H) by keeping only the representations associated to the class $[c_g]$, and by choosing a lift in Schur(H) of each conjugacy class of H (different choices of the lifts lead to projectively equivalent representations).

It only remains to determine which irreducible representations of Schur(H) correspond to the class $[c_g]$. Consider an irreducible projective representation ρ of H associated with the 2-cocycle c_g. For any commuting pair $h,k \in H$, $hk = kh$, we have

$$\rho(h)\rho(k)\rho(h)^{-1}\rho(k)^{-1} = \frac{c_g(h,k)}{c_g(k,h)}\ . \tag{178}$$

(Note that $\frac{c_g(h,k)}{c_g(k,h)}$ only depends on the class $[c_g]$ and not on the representative cocycle c_g.) Thus, any representation σ of Schur(H) in the class $[c_g]$ must satisfy

$$\sigma(\tilde h\tilde k\tilde h^{-1}\tilde k^{-1}) = \frac{c_g(h,k)}{c_g(k,h)}\ , \tag{179}$$

where $\tilde h, \tilde k$ are some lifts of h,k in Schur(H). It is easy to see that the commutator $\tilde h\tilde k\tilde h^{-1}\tilde k^{-1}$ is an element of $M(H)$, and that it does not depend of the choice of the lifts. In fact, the commutators of this form generate $M(H)$, and if a representation σ satisfies (179) for a set of generators of $M(H) = (H^2(H, U(1)))^*$, then it must be associated with the class $[c_g]$. This condition can be easily tested for each irreducible representation of Schur(H), given our explicit knowledge of the cocycle c_g.

D.1. **Character Tables.** In this section we collect some information about the centralisers $C_{M_{24}}(g)$ of representatives of each M_{24} conjugacy class $[g]$, in particular a (rough) description of the group structure and the group order. Our notation is as follows:

$G = N.Q$	group G containing a normal subgroup N and such that $G/N \cong Q$
$N \rtimes Q$	(left) semidirect product of N and Q
$\mathbb{Z}_n$	cyclic group of order n
S_n	group of permutations (symmetric group) of n objects
A_n	group of even permutations (alternating group) of n objects
D_n	dihedral group of order n
$PSL_n(q)$	projective special linear group over the n-dim. vector space over the finite field $\mathbb{F}_q$

Furthermore, for each class $[g]$, we specify whether the representation carried by the g-twisted sector $\mathcal{H}_g$ is (projectively equivalent to) a linear representation, or whether it is genuinely projective; in the latter case we describe a minimal central extension with respect to which the representation is linear. Finally, we provide the character table of $C_{M_{24}}$ for the relevant projective equivalence class. The names of the conjugacy classes are chosen to correspond to the ATLAS names of M_{24} classes, with additional indices in case of redundancy. We adopt the following notation for algebraic numbers

$$\varepsilon_n = e^{\frac{2\pi i}{n}} \ , \qquad\qquad e_p^{\pm} = \frac{1}{2}(1 \pm i\sqrt{p}) \ .$$

Classes 11A, 12A, 12B, 14AB, 15AB, 21AB, 23AB

When g is in one of these classes, the centralizer $C_{M_{24}}(g)$ is the cyclic group $\langle g \rangle$ and all representations in the g-twisted sector are (projectively equivalent to) linear representations. Thus, all irreducible representations are one dimensional, and a useful choice for the corresponding (projective) characters χ_k, $k = 1, \ldots, o(g)$ is

$$\chi_k(g^a) = e^{2\pi i \frac{a}{o(g)}(k - \frac{1}{\ell(g)})} \ , \qquad (180)$$

$a = 0, \dots, o(g) - 1$, where $\ell(g)$ is the length of the shortest cycle of g when considered as a permutation of 24 objects. Indeed, the characters (180) correspond to the standard definition $\rho_g(g^a) = e^{2\pi i a (L_0 - \tilde{L}_0)}$ for the action of $\langle g \rangle$ in the g-twisted sector.

Class 2A

Table 12. Character table for the centralizer of classes 6AB. NOTE: There is an accidental isomorphism $C_{M_{24}}(6A) \cong C_{M_{24}}(6B)$, therefore the character table is given only once. However, following our conventions, we give different names to the conjugacy classes depending on whether the group is $C_{M_{24}}(6A)$ or $C_{M_{24}}(6B)$.

Classes 7A and 7B

TABLE 15. Character table for the centralizer of class 10A.

Appendix E. Decompositions of twisted sectors

In this section we give the decomposition of the first 20 representation spaces $\mathcal{H}_g^n$ for all non-isomorphic twisted sectors. In each table, the integer in the i'th row and the r'th column is the multiplicity $h_{i,r}$ of the irreducible representation χ_i (numbered as in the corresponding character table) in the representation $\rho_{g,r}$ of eq. (6). When the centraliser $C_{M_{24}}(g)$ is a cyclic group $\mathbb{Z}_N$, $N = o(g)$ (classes 11A, 12A, 12B, 14AB, 15AB, 21AB, 23AB), the multiplicity $h_{i,r}$ of the (projective) irreducible characters χ_i (see eq. (180)) is only non-zero if $Nr + 1/\ell(g) \equiv i \mod N$, where $\ell(g)$ is the length of the shortest cycle of g as a permutation of 24 objects; then, only these values of $h_{i,r}$ are given.

Mathieu twining characters for K3

Matthias R. Gaberdiel, Stefan Hohenegger and Roberto Volpato

Institut für Theoretische Physik
ETH Zurich
CH-8093 Zürich

Abstract: The analogue of the McKay-Thompson series for the proposed Mathieu group action on the elliptic genus of K3 is analysed. The corresponding NS-sector twining characters have good modular properties and satisfy remarkable replication identities. These observations provide strong support for the conjecture that the elliptic genus of K3 carries indeed an action of the Mathieu group $\mathbb{M}_{24}$.

1. Introduction and summary

Recently, Eguchi, Ooguri and Tachikawa [11] have observed that the elliptic genus of K3 seems to carry an action of the Mathieu group $\mathbb{M}_{24}$. More specifically, they noticed that the expansion coefficients of the elliptic genus of K3, when written in terms of the elliptic genera of $\mathcal{N} = 4$ superconformal representations, can be expressed in terms of dimensions of Mathieu group representations. This intriguing observation is very reminiscent of the famous observation of McKay and Thompson who found that the Fourier expansion coefficients of the J-function can be written in terms of dimensions of representations of the Monster group. This led to a development that is now usually referred to as 'Monstrous Moonshine', see [18] for a nice review. One of the upshots of this analysis is that the J-function can be thought of as the partition function of a self-dual conformal field theory, the 'Monster conformal field theory' [3, 16], whose automorphism group is precisely the Monster group.

Unlike the situation of the Monster group, the dimensions of the Mathieu group are rather small, and thus there is a certain amount of arbitrariness in the above observation regarding the elliptic genus of K3. It would therefore be very interesting to subject this proposal to some more stringent tests. In the context of Monstrous Moonshine, one of the tests concerned the so-called McKay-Thompson series [21]. They are obtained from the J-function by replacing the dimensions of the Monster group representations by their characters with respect to a Monster group element. (In retrospect, they are the 'twining characters', where one inserts into the partition function of the Monster conformal field theory a Monster group element.) It was observed early on by Conway & Norton that these McKay-Thompson series have nice modular properties and satisfy remarkable replication identities [5]. The former identities have a natural interpretation in terms of standard orbifold arguments [22], while the latter can be obtained by considering the twining characters for the symmetric power theories (as follows from our analysis in section 3.2).

In this paper we study the analogues of the McKay-Thompson series for the case of K3, *i.e.* the twining elliptic genera where we insert a Mathieu group element into the trace. Using the proposed decomposition of the coefficients of the elliptic genus in terms of Mathieu group representations, we can calculate the first few coefficients of these twining genera explicitly. As for the McKay-Thompson series, standard orbifold arguments suggest that they must have good modular properties. At least for the group elements of small order, these modular constraints are very constraining, and we can use them to determine the twining genera exactly. We furthermore show that they satisfy highly non-trivial replication identities, relating twining genera corresponding to different group elements to one another. The fact that all of this works out represents a very stringent consistency check for the proposal of [11]; indeed, our analysis implies that one of the identifications of the coefficients in terms of Mathieu representation dimensions must be different to what was proposed in [11]. Our analysis thus gives strong support to the idea that the elliptic genus of K3 carries indeed an action of the Mathieu group $\mathbb{M}_{24}$. It furthermore suggests that this is in some sense the natural supersymmetric generalisation of Monstrous Moonshine to the case of $\mathbb{M}_{24}$. (A different proposal for the analogue of Monstrous Moonshine for $\mathbb{M}_{24}$ was made some time ago in the context of self-dual bosonic conformal field theories by Dong & Mason [8].)

The paper is organised as follows. In section 2 we recall some basic properties of elliptic genera and their modular properties. We also review how the elliptic genus of the symmetric power theory can be calculated in terms of the original elliptic genus. In section 3 we briefly describe the proposal of [11], and then calculate the twining elliptic genera and their associated NS twining characters. We explain in detail which modular properties the latter should possess. Using this insight we then identify the twining characters for group elements of small order in terms of known theta functions (or standard McKay-Thompson series), see (3.14). In section 3.2 we explain what replication formulae one should expect, and demonstrate in a large number of examples, that these identities are indeed satisfied for the twining characters of K3. Our conclusions and avenues for future research are described in section 4. We have relegated some of the more technical material to an appendix.

2. Elliptic genera and their modular properties

Let us begin by reviewing some standard material about elliptic genera and their Jacobi and modular properties. The elliptic genus of an $\mathcal{N}=2$ superconformal algebra is defined by

$$\phi(\tau,z) = \mathrm{Tr}_{\mathcal{H}_{RR}}\Big(q^{L_0-\frac{c}{24}} e^{2\pi i z J_0} (-1)^F \, \bar{q}^{\bar{L}_0-\frac{\bar{c}}{24}} (-1)^{\bar{F}}\Big) \ . \tag{2.1}$$

For the right-movers (whose modes are denoted by a bar), only the ground states contribute, and hence the above expression is in fact independent of $\bar{q}$. As is well-known [20], the modularity properties of conformal field theory together with spectral flow invariance and unitarity imply that the elliptic genus is a *weak Jacobi form* of index $m = \frac{c}{6}$ and weight zero [14]. A weak Jacobi form $\phi(\tau, z)$ of weight w and index $m \in \mathbb{Z}$, with $(\tau, z) \in \mathbb{H} \times \mathbb{C}$, satisfies the transformation laws

$$\phi\Big(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\Big) = (c\tau + d)^w \, e^{2\pi i m \frac{cz^2}{c\tau+d}} \, \phi(\tau, z) \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, \mathbb{Z}) \ , \tag{2.2}$$

$$\phi(\tau, z + \ell\tau + \ell') = e^{-2\pi i m(\ell^2\tau + 2\ell z)} \phi(\tau, z) \qquad \ell, \ell' \in \mathbb{Z} \ , \tag{2.3}$$

and has a Fourier expansion

$$\phi(\tau, z) = \sum_{n \geq 0, \ell \in \mathbb{Z}} c(n, \ell) q^n y^\ell \tag{2.4}$$

with $c(n, \ell) = (-1)^w c(n, -\ell)$. For the case of K3 that will concern us primarily in this paper, the elliptic genus equals [10]

$$\phi_{K3}(\tau, z) = 2y + 20 + 2y^{-1} + q\Big(20y^2 - 128y + 216 - 128y^{-1} + 20y^{-2}\Big) + \mathcal{O}(q^2) \ , \tag{2.5}$$

where $y = e^{2\pi i z}$. For the following it will be convenient to rescale the elliptic genus by a factor of $\frac{1}{2}$, *i.e.* to define

$$\phi_{1\mathrm{A}}(\tau, z) = \frac{1}{2}\phi_{K3}(\tau, z) = y + 10 + y^{-1} + q\Big(10y^2 - 64y + 108 - 64y^{-1} + 10y^{-2}\Big) + \mathcal{O}(q^2) \ , \tag{2.6}$$

which is then directly equal to the standard weak Jacobi form $\phi_{0,1}$.

To understand the analogy with the bosonic Monster conformal field theory, it is useful to consider instead the NS-sector version of the elliptic genus, which is obtained by applying one half unit of spectral flow to the left-movers, *i.e.* $l = l' = \frac{1}{2}$ in (2.3); the shift by $l = \frac{1}{2}$ is familiar from the spectral flow automorphism

$$L_0 \mapsto L_0 + l\, J_0 + l^2 \, \frac{c}{6} \ , \qquad J_0 \mapsto J_0 + l\, \frac{c}{3} \ , \tag{2.7}$$

while the shift by $l' = \frac{1}{2}$ is required so as to remove the $(-1)^F$ from the trace, in order to get the standard NS-sector partition function without an insertion of $(-1)^F$. The resulting NS-sector partition function will always be denoted by

$$\chi(\tau, z) = \exp\left[2\pi i m \left(\frac{\tau}{4} + z + \frac{1}{2}\right)\right] \phi\left(\tau, z + \frac{\tau}{2} + \frac{1}{2}\right) \ . \tag{2.8}$$

Using the transformation properties of a Jacobi form it follows easily that

$$\begin{aligned} \chi(-1/\tau, z/\tau) &= (-1)^m e^{2\pi i \frac{mz^2}{\tau}} \, \chi(\tau, z) \\ \chi(\tau + 2, z) &= (-1)^m \, \chi(\tau, z) \ . \end{aligned} \tag{2.9}$$

In order to obtain a standard modular form (rather than a Jacobi form) we may then put $z = 0$; the resulting function (which we shall simply denote by $\chi(\tau)$) is non-trivial, and it has simple transformation laws under the congruence subgroup $\Gamma_\theta = \langle T^2, S\rangle$. For m even we have a strict modular function and for m odd we have a function with multiplier system given by -1 on the two generators [17],

$$\chi(-1/\tau) = (-1)^m \chi(\tau) \ , \qquad \chi(\tau+2) = (-1)^m \chi(\tau) \ . \tag{2.10}$$

For the case of K3 it is explicitly given as [17]

$$\chi_{1\mathrm{A}}(\tau) = \frac{1}{2}\chi_{K3}(\tau) = \kappa(\tau) = \left(\frac{2\vartheta_4(\tau)}{\vartheta_2(\tau)}\right)^2 - \left(\frac{2\vartheta_2(\tau)}{\vartheta_4(\tau)}\right)^2 = q^{-\frac{1}{4}}(1 - 20\, q^{\frac{1}{2}} + \cdots) \ . \tag{2.11}$$

Our conventions regarding the theta functions are described in the appendix.

It should be noted that specialising to $z = 0$ in the NS-sector does not loose any information. Indeed, the NS character $\chi_{1\mathrm{A}}(\tau)$ determines $\phi_{1\mathrm{A}}(\tau, \frac{1}{2})$ by setting $z = 0$ in

$$\chi_{1\mathrm{A}}(\tau, z) = \phi_{1\mathrm{A}}(\tau, 0)\, \frac{\vartheta_4(\tau, z)^2}{\vartheta_2(\tau, 0)^2} - \phi_{1\mathrm{A}}(\tau, \tfrac{1}{2}) \frac{\vartheta_3(\tau, z)^2}{\vartheta_2(\tau, 0)^2} \ , \tag{2.12}$$

and using that the coefficient of the first term is simply the Witten index $\phi_{1\mathrm{A}}(\tau, 0) = 12$. On the other hand, this information determines the full elliptic genus via

$$\phi_{1\mathrm{A}}(\tau, z) = \phi_{1\mathrm{A}}(\tau, 0)\, \frac{\vartheta_2(\tau, z)^2}{\vartheta_2(\tau, 0)^2} + \phi_{1\mathrm{A}}(\tau, \tfrac{1}{2})\, \frac{\vartheta_1(\tau, z)^2}{\vartheta_2(\tau, 0)^2} \ . \tag{2.13}$$

Thus the knowledge of $\chi_{1\mathrm{A}}(\tau)$ is equivalent to that of $\phi_{1\mathrm{A}}(\tau, z)$. The advantage of working with $\chi_{1\mathrm{A}}(\tau)$ is that it is the natural supersymmetric analogue of the partition function of a bosonic conformal field theory for which Monstrous Moonshine was originally formulated.

2.1 Symmetric powers

For the following it will also be important to consider the symmetric powers of the K3 conformal field theory. Given any $\mathcal{N} = 2$ superconformal field theory $\mathcal{H}$, we can consider the symmetric power theory

$$\mathcal{H}^{(p)} = \underbrace{\Big(\mathcal{H} \otimes \cdots \otimes \mathcal{H}\Big)}_{\text{p times}} / \mathbb{Z}_p \ , \tag{2.14}$$

where the generator π of $\mathbb{Z}_p$ is the cyclic permutation of length p. We shall concentrate in the following on the case when p is prime; then all elements of $\mathbb{Z}_p$ are cyclic permutations of cycle length p. Given the elliptic genus of the original $\mathcal{H}$ theory, we can then determine the elliptic genus of $\mathcal{H}^{(p)}$ [6]. From the untwisted sector of the $\mathbb{Z}_p$ orbifold we get the contribution

$$\phi_U^{(p)}(\tau, z) = \frac{1}{p}\Big(\big(\phi(\tau, z)\big)^p + (p-1)\, \phi(p\tau, pz) \Big) \ . \tag{2.15}$$

Here the first term is the elliptic genus without the insertion of any orbifold generator, while the second term gives the contributions coming from π^l with $l = 1, \ldots, p-1$. Since each such π^l is a cyclic permutation of order p, only the states of the form $(u \otimes u \otimes \cdots \otimes u)$ contribute, and this leads to $\phi(p\tau, pz)$ for each of these terms.

There are $(p-1)$ twisted sectors, and each of them contributes the same, thus giving for the whole twisted sector

$$\phi_T^{(p)}(\tau, z) = \frac{(p-1)}{p} \sum_{l=0}^{p-1} \phi\big(\tfrac{\tau+l}{p}, z\big) \ , \tag{2.16}$$

where the sum over l implements the orbifold projection in the twisted sector. Thus the elliptic genus of the symmetric power theory is (for p prime)

$$\phi^{(p)}(\tau, z) = \frac{1}{p}\,\big(\phi(\tau, z)\big)^p + \frac{(p-1)}{p}\, H_p\phi(\tau, z) \ , \tag{2.17}$$

where H_p denotes the action of the Hecke operator

$$H_p\phi(\tau, z) = \phi(p\tau, pz) + \sum_{l=0}^{p-1} \phi\big(\tfrac{\tau+l}{p}, z\big) \ . \tag{2.18}$$

It is well known that (2.17) is again a weak Jacobi form of index mp provided that $\phi(\tau, z)$ has index m [6]. For example, this follows directly from the fact that the Hecke operator (2.18) maps weak Jacobi forms to weak Jacobi forms, see [14].

For our purposes, it is also convenient to rewrite (2.18) for the NS-sector character $\chi^{(p)}(\tau)$. The result depends on whether $p = 2$ or p odd. For $p = 2$ we find

$$\chi^{(2)}(\tau) = \chi\left(2\tau, \tfrac{1}{2}\right) + \phi\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) + (-1)^m \phi\left(\tfrac{\tau}{2} + \tfrac{1}{2}, 0\right) \ , \tag{2.19}$$

where $\chi(\tau, z)$ is the NS-sector function defined in (2.8), while $\phi(\tau, z)$ is the elliptic genus in the R-sector. In particular, the last expression is therefore actually a constant since $\phi(\tau, 0)$ is the Witten index. The emergence of the R-sector as the 'twisted' sector of the NS-sector is familiar from standard $\mathbb{Z}_2$ orbifold considerations. For the case of the K3 character the relevant formula is[1]

$$\begin{aligned} \chi_{1\mathrm{A}}^{(2)}(\tau) &= \left[\left(\frac{2\vartheta_3(2\tau)}{\vartheta_2(2\tau)}\right)^2 - \left(\frac{2\vartheta_2(2\tau)}{\vartheta_3(2\tau)}\right)^2\right] + \left[\left(\frac{2\vartheta_3(\frac{\tau}{2})}{\vartheta_4(\frac{\tau}{2})}\right)^2 - \left(\frac{2\vartheta_4(\frac{\tau}{2})}{\vartheta_3(\frac{\tau}{2})}\right)^2\right] - 12 \\ &= \chi_{1\mathrm{A}}(\tau)^2 + 36 \ . \end{aligned} \tag{2.20}$$

The fact that the left-hand side can be expressed in terms of a polynomial of the original K3 character is a consequence of $\chi_{1\mathrm{A}}(\tau)^2$ being a Hauptmodul (without any multiplier system) for the congruence subgroup Γ_θ. Since the left-hand is a modular form for Γ_θ (without any multiplier system), it must therefore be a polynomial of $\chi_1(\tau)^2$.

For $p > 2$ (recall that p is prime, and therefore now odd) the formula is instead

$$\chi^{(p)}(\tau) = \chi(p\tau) + \sum_{l=0}^{p-1} \chi\big(\tfrac{\tau+4l}{p}\big) \ , \qquad p \geq 3 \text{ prime.} \tag{2.21}$$

---

[1] We shall state these and any following formulae for the rescaled elliptic genera, see (2.6) and (2.11).

For the case of the K3 character we then find, for example for $p = 3$,

$$\begin{aligned} \chi^{(3)}_{1\mathrm{A}}(\tau) &= \chi_{1\mathrm{A}}(3\tau) + \chi_{1\mathrm{A}}\left(\tfrac{\tau}{3}\right) + \chi_{1\mathrm{A}}\left(\tfrac{\tau+4}{3}\right) + \chi_{1\mathrm{A}}\left(\tfrac{\tau+8}{3}\right) \\ &= \chi_{1\mathrm{A}}(\tau)^3 + 60\,\chi_{1\mathrm{A}}(\tau)\ . \end{aligned} \tag{2.22}$$

By the same token as above, this formula follows from the fact that the left-hand side is again a modular form (with multiplier system -1 on S and T^2) for Γ_θ, and that the Hauptmodul for these is $\chi_{1\mathrm{A}}(\tau)$. Because of the non-trivial multipler system of the left-hand-side the expression now only involves odd powers of $\chi_{1\mathrm{A}}(\tau)$.

We should note that these relations are the natural analogue of the replication formulae for the J-function, which read for $p = 2$ and $p = 3$

$$\begin{aligned} J(2\tau) + J\left(\tfrac{\tau}{2}\right) + J\left(\tfrac{\tau+1}{2}\right) &= J^2(\tau) - 2a_1 \\ J(3\tau) + J\left(\tfrac{\tau}{3}\right) + J\left(\tfrac{\tau+1}{3}\right) + J\left(\tfrac{\tau+2}{3}\right) &= J^3(\tau) - 3a_1 J(\tau) - 3a_2\ . \end{aligned} \tag{2.23}$$

Here $J(\tau)$ is the famous J-function

$$J(\tau) = \sum_{k=-1}^{\infty} a_k q^k = q^{-1} + 196884q + 21493760q^2 + \mathcal{O}(q^3)\ , \tag{2.24}$$

that plays a central role in Monstrous moonshine, see [18] for a nice review.

3. Mathieu symmetry and twining characters

The elliptic genus of K3 can be thought of as the partition function of the $\mathcal{N} = 2$ half-BPS states of type II string theory on K3. It is suggested by the work of [11] that the space of these half-BPS states carries an action of the Mathieu group $\mathbb{M}_{24}$. Indeed, it was found in [11], following on from earlier work [9], that the elliptic genus of K3 can be written as

$$\phi_{1\mathrm{A}}(\tau, z) = 24\,\mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=0}(\tau, z) + \sum_{n=0}^{\infty} A_n\,\mathrm{ch}^{\mathcal{N}=4}_{h=n+\frac{1}{4},l=\frac{1}{2}}(\tau, z)\ , \tag{3.1}$$

where $\mathrm{ch}^{\mathcal{N}=4}_{h=\frac{1}{4},l=0}$ is the elliptic genus of the short $\mathcal{N} = 4$ representation with $h = \frac{1}{4}$ and $l = 0$ — see [12, 13] for an explicit formula — while

$$\mathrm{ch}^{\mathcal{N}=4}_{h,l=\frac{1}{2}}(\tau, z) = q^{h-\frac{3}{8}}\,\frac{\vartheta_1(\tau, z)^2}{\eta(\tau)^3} \tag{3.2}$$

is the elliptic genus of a long $\mathcal{N} = 4$ representation.[2] The observation of [11] was that the coefficients A_n can be written in terms of dimensions of irreducible representations of the Mathieu group $\mathbb{M}_{24}$. (The character table of $\mathbb{M}_{24}$, from which one can read off in particular the dimensions of the irreducible representations is given in the appendix.) More explicitly,

$$\begin{array}{rclcrcl} 24 &=& \mathbf{23} + \mathbf{1} & \qquad & -A_0 = 2 &=& \mathbf{1} + \mathbf{1} \\ A_1 = 90 &=& \mathbf{45} + \overline{\mathbf{45}} & & A_2 = 462 &=& \mathbf{231} + \overline{\mathbf{231}} \\ A_3 = 1440 &=& \mathbf{770} + \overline{\mathbf{770}} & & A_4 = 4554 &=& \mathbf{2277} + \overline{\mathbf{2277}} \\ A_5 = 11592 &=& 2 \cdot \mathbf{5796} & & A_6 = 27830 &=& 2 \cdot \mathbf{3520} + 2 \cdot \mathbf{10395} \end{array} \tag{3.3}$$

---

[2] Strictly speaking, the $\mathcal{N} = 4$ representation with $n = 0$ ($h = \frac{1}{4}$) is short, and thus (3.2) for $h = \frac{1}{4}$ is not the elliptic genus of a single representation, but rather involves a sum of representations.

and

$$A_7 = 61686 = 2 \cdot \mathbf{1771} + 2 \cdot \mathbf{2024} + 2 \cdot \mathbf{5313} + 2 \cdot \mathbf{5796} + 2 \cdot \mathbf{5544} + 2 \cdot \mathbf{10395} \ . \tag{3.4}$$

Note that, relative to [11], we have absorbed the prefactor of 2 in [11, eq. (1.11)] into the definition of A_n. Then we can write the A_n in terms of real representations, *i.e.* sums of representations and their conjugate representations. Furthermore, for reasons that will be explained momentarily, our expression for A_7 differs from the decomposition suggested in [11]. We should mention though that while A_7 given in (3.4) is consistent with what is done below, it is not uniquely specified by this.

3.1 Explicit formulae for the twining characters

Obviously, as is apparent from the last comment, there is much arbitrariness in these decompositions, and they are only a suggestive hint of some underlying deeper structure. The main aim of this paper is to subject this proposal to a much more refined test. To this end we shall study the corresponding '*twining genus*', *i.e.* the analogues of the McKay-Thompson series in the case of Monstrous Moonshine. This is to say, we shall calculate not just the elliptic genus itself, but the elliptic genus with the insertion of a group element $g \in \mathbb{M}_{24}$

$$\phi_g(\tau, z) = \mathrm{Tr}_{\mathcal{H}_{RR}} \Big(g \, q^{L_0 - \frac{c}{24}} e^{2\pi i z J_0} (-1)^F \, \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} (-1)^{\bar{F}} \Big) \ . \tag{3.5}$$

Technically speaking, the calculation of ϕ_g differs from ϕ by replacing A_n in (3.1) by the characters of g in the representations described in (3.3). Obviously, the character of g only depends on its conjugacy class, and thus all the information we need is contained in the character table of $\mathbb{M}_{24}$ that is included in the appendix.

One immediate problem with this approach is that we only know how to write A_n in terms of dimensions of representations of $\mathbb{M}_{24}$ for the first few values of n. We can therefore only directly determine the low powers of q of the twining genera ϕ_g. If this was all there was to it, this would not be particularly interesting, and it would certainly not lead to any non-trivial consistency check of the proposal. The reason why interesting information can be obtained in this manner is that the twining genera must have fairly specific modular properties. One way to see this explicitly is to translate the R-sector series $\phi_g(\tau, z)$ into the NS-sector as in (2.8), and set $z = 0$. The resulting expression is the NS-sector twining character $\chi_g(\tau)$, *i.e.* the character in the NS-sector with the insertion of the Mathieu group element g. Note that by the same arguments as above we are not loosing any information in doing so, because the analogues of (2.12) and (2.13) are

$$\chi_g(\tau, z) = \phi_g(\tau, 0) \, \frac{\vartheta_4(\tau, z)^2}{\vartheta_2(\tau, 0)^2} - \phi_g(\tau, \tfrac{1}{2}) \frac{\vartheta_3(\tau, z)^2}{\vartheta_2(\tau, 0)^2} \ , \tag{3.6}$$

and

$$\phi_g(\tau, z) = \phi_g(\tau, 0) \, \frac{\vartheta_2(\tau, z)^2}{\vartheta_2(\tau, 0)^2} + \phi_g(\tau, \tfrac{1}{2}) \, \frac{\vartheta_1(\tau, z)^2}{\vartheta_2(\tau, 0)^2} \ , \tag{3.7}$$

where now the constant term equals

$$\phi_g(\tau, 0) = \tfrac{1}{2} \, \mathrm{Tr}_{\mathbf{23} \oplus \mathbf{1}}(g) \ . \tag{3.8}$$

Thus we can reconstruct the full twining genus $\phi_g(\tau,z)$ from the twining character $\chi_g(\tau)$, and vice versa. In terms of the usual box notation, $\chi_g(\tau)$ corresponds to

$$\chi_g(\tau) \longleftrightarrow (-1,\mathbf{1})\ \underset{(-1,\mathbf{g})}{\boxed{}} \tag{3.9}$$

where the '-1's indicate that the trace is taken in the NS-sector, and without any insertion of $(-1)^F$, respectively. Under a modular transformation it is believed that these twining and twisted characters transform as

$$h\ \underset{g}{\boxed{}} \quad \xrightarrow{\begin{pmatrix} a & b \\ c & d \end{pmatrix}} \quad h^d g^c\ \underset{g^a h^b}{\boxed{}} \tag{3.10}$$

For the case at hand, it therefore follows that the twining character corresponding to (3.9) is invariant (possibly up to some phase) under a modular transformation provided that

$$a+b,\ c+d \in 2\mathbb{Z}+1\ , \qquad c = 0 \mod o(g), \tag{3.11}$$

where $o(g)$ is the order of the group element g. [Here we have used that the group operation is $(\epsilon_1, g_1)\cdot(\epsilon_2, g_2) = (\epsilon_1\epsilon_2, g_1\cdot g_2)$, where $\epsilon_j \in \{\pm 1\}$ and $g_i \in \mathbb{M}_{24}$. We have furthermore used that the conditions in (3.11) together with the requirement that $ad-bc=1$ imply that $(a,o(g))=1$. For the Mathieu group $\mathbb{M}_{24}$ it then follows that g^a is in the same conjugacy class as g.] The subgroup of $SL(2,\mathbb{Z})$ that is characterised by (3.11) contains in particular

$$\Gamma^g = \Gamma_\theta \cap \Gamma_0(o(g))\ , \tag{3.12}$$

where Γ_θ was introduced before, and

$$\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2,\mathbb{Z})\ :\ c = 0 \bmod (N) \right\}\ . \tag{3.13}$$

The property of a function to be modular invariant under Γ^g (possibly up to some multiplier system) is a very strong condition, and knowing the first few terms usually determines the function uniquely.

Thus the non-trivial consistency test we will be performing proceeds as follows. Using the low-lying decomposition (3.3), we can calculate the first few coefficients of the twining characters $\chi_g(\tau)$ explicitly. On the other hand, we know that these functions must be invariant under Γ^g, and thus there is the highly non-trivial consistency condition whether this ansatz can be completed in a Γ^g-invariant manner. The results we find are consistent with A_n given in (3.3) and (3.4), but not with the formula for A_7 suggested in [11]. They represent a highly non-trivial consistency condition for the conjecture of [11] that the elliptic genus of K3 carries an action by the Mathieu group $\mathbb{M}_{24}$.

The constraints coming from the modular properties are tighter the larger Γ^g is, *i.e.* the smaller the order of the group element is. In particular, we should therefore expect to have good control over the twining characters corresponding to group elements of small order. Indeed, this turns out to be correct, and we have even found closed form expressions that match with the low lying coefficients and have the correct modular properties. More specifically, we find that — in the following the label refers to the conjugacy class of the Mathieu group element that is described in the appendix

$$\begin{aligned}
\chi_{1\mathrm{A}}(\tau) &= \kappa(\tau) = T_{[8\mathrm{a}]}(\tfrac{\tau}{4}) \qquad \text{— see eq. (2.11)} \\
\chi_{2\mathrm{A}}(\tau) &= 4\,\frac{\vartheta_4(\tau)^2}{\vartheta_2(\tau)^2} \simeq T_{[16\mathrm{b}]}(\tfrac{\tau}{4}) \\
\chi_{2\mathrm{B}}(\tau) &= 4\,\frac{\vartheta_3(\tau)^2}{\vartheta_2(\tau)^2} \simeq T_{[16\mathrm{b}]}(\tfrac{\tau}{4}) \\
\chi_{3\mathrm{A}}(\tau) &= \left(\frac{\eta(\tau)}{\eta(3\tau)}\right)^3 \frac{\vartheta_3(3\tau)}{\vartheta_3(\tau)} = T_{[24\mathrm{c}]}(\tfrac{\tau}{4}) \\
\chi_{4\mathrm{A}}(\tau) &= \left(\frac{\eta(\tau)\,\eta(2\tau)}{\eta(\frac{\tau}{2})\,\eta(4\tau)}\right)^4 = T_{[16\mathrm{A}]}(\tfrac{\tau}{4}) \\
\chi_{4\mathrm{B}}(\tau) &= 2\,\frac{\vartheta_3(2\tau)}{\vartheta_2(2\tau)} = T_{[16\mathrm{B}]}(\tfrac{\tau}{4}) \\
\chi_{4\mathrm{C}}(\tau) &= 4\,\frac{\vartheta_3(\tau)^2\vartheta_3(2\tau)}{\vartheta_2(\tau)^2\vartheta_4(2\tau)} \\
\chi_{5\mathrm{A}}(\tau) &= q^{-\frac{1}{4}}\Big(1+3\,q+4\,q^{\frac{3}{2}}+4\,q^2+4\,q^{\frac{5}{2}}+\cdots\Big) = T_{[40\mathrm{a}]}(\tfrac{\tau}{4}) \\
\chi_{6\mathrm{A}}(\tau) &= \left(\frac{\eta(\frac{3}{2}\tau)\,\eta(2\tau)}{\eta(\frac{\tau}{2})\,\eta(6\tau)}\right)^2 = T_{[24\mathrm{H}]}(\tfrac{\tau}{4})\,.
\end{aligned} \tag{3.14}$$

Our conventions for the Jacobi theta functions, and the first few coefficients of the power series expansions of the relevant McKay-Thompson series are given in the appendix. We have again normalised these functions so that they start with $1 \cdot q^{-\frac{1}{4}}$, compare (2.11). In most cases, the functions can be identified with a standard McKay-Thompson series $T_{[*]}$ (evaluated at $\frac{\tau}{4}$) — if this is the case the corresponding identity is given above. For the conjugacy class 2A and 2B the coefficients only agree with the McKay-Thompson series up to some signs; this is indicated by $\simeq$. In all cases we have explicitly checked that these functions are invariant under Γ^g in (3.12) up to some multiplier system. The multiplier system is non-trivial in all cases since all twining characters transform as -1 under $T^2 \in \Gamma^g$. In addition, $\chi_{1\mathrm{A}}$ transforms as -1 under S (compare (2.9)), while $\chi_{4\mathrm{C}}$ transforms as $-i$ under ST^4S. (We have not checked the precise form of the multiplier system for the class corresponding to 5A.)

The attentive reader will notice that (3.14) accounts for all twining characters of group elements up to order 6, except for the ones corresponding to 3B and 6B. While we have not managed to find any closed formulae for them — explicit formulae for the first few coefficients of their power series expansion are given in the appendix — we have an indirect argument that suggests that at least the twining character corresponding to 3B has good modular properties; this will be explained in the following section. We should also mention that some of these conjugacy classes are actually contained in $\mathbb{M}_{23}$ — these are the conjugacy classes 1A, 2A, 3A, 4B, 5A, 6A — while the others (2B, 3B, 4A, 4C) lie only in $\mathbb{M}_{24}$ but not in $\mathbb{M}_{23}$. These latter classes are characterised by the property that $\mathrm{Tr}_{\mathbf{23}\oplus\mathbf{1}}(g) = 0$. For them the relation between the twining characters and the twining genera (see (3.6) and (3.7)) is therefore particularly simple, and we have

$$\phi_g(\tau, z) = -\chi_g(\tau)\, \frac{\vartheta_1(\tau,z)^2}{\vartheta_3(\tau,0)^2} \qquad \text{if } \mathrm{Tr}_{\mathbf{23}\oplus\mathbf{1}}(g) = 0. \tag{3.15}$$

Thus for the elements in $\mathbb{M}_{24}$ that are not in $\mathbb{M}_{23}$, the modular properties of $\phi_g(\tau, z)$ are a direct consequence of those of $\chi_g(\tau)$. However, apart from this simplification, we do not see any difference between the behaviour of the elements that lie in $\mathbb{M}_{23}$ and those that do not.

3.2 Replication formulae

One of the remarkable properties of the McKay-Thompson series in Monstrous Moonshine are their replication relations. They are a direct generalisation of the J-function replication identities (2.23) to the McKay-Thompson series. In the following we want to give a conformal field theoretic argument that suggests that similar relations should also hold for the twining characters of K3, and more specifically, what precise form they should take. Incidentally, if we applied the following argument to the Monster theory it would give a physics explanation of the replication identities of Monstrous Moonshine.

The idea of the argument is very simple. If the $\mathcal{N} = 2$ half-BPS spectrum of K3 carries an action of the Mathieu group $\mathbb{M}_{24}$, then the same will apply to the symmetric power theories where $g \in \mathbb{M}_{24}$ acts diagonally on all p factors so as to commute with the orbifold action. But if this is so, then we can also consider the twining character corresponding to $g \in \mathbb{M}_{24}$ for the p^{th} symmetric power theory. Given our detailed understanding of the orbifold theory, we can determine how g acts on the various terms in (2.17) or indeed on the different terms in $H_p\phi(\tau, z)$. The first term corresponds to the untwisted sector contribution where the cyclic permutation generator has been inserted into the trace. This implies that only the states of the form $(u \otimes u \otimes \cdots \otimes u)$ contribute. Inserting the diagonal group element $g \in \mathbb{M}_{24}$ then leads to $\phi_{g^p}(p\tau, pz)$. The other terms of $H_p\phi(\tau, z)$ come from the twisted sector, and the natural action of $g \in \mathbb{M}_{24}$ is simply described by replacing ϕ by ϕ_g. Thus we are led to claim that the twining genus for the Hecke part of the p^{th} symmetric power theory is given by

$$\big(H_p\phi\big)_g(\tau, z) = \phi_{g^p}(p\tau, pz) + \sum_{l=0}^{p-1} \phi_g\big(\tfrac{\tau+l}{p}, z\big) \ . \tag{3.16}$$

Translated into the NS-sector characters we then have for $p = 2$

$$\chi^{(2)}_g(\tau) = \chi_{g^2}\left(2\tau, \tfrac{1}{2}\right) + \phi_g\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) + (-1)^m \phi_g\left(\tfrac{\tau}{2} + \tfrac{1}{2}, 0\right) \ , \tag{3.17}$$

while for $p > 2$ the formula is

$$\chi_g^{(p)}(\tau) = \chi_{g^p}(p\tau) + \sum_{l=0}^{p-1} \chi_g\left(\tfrac{\tau+4l}{p}\right) , \qquad p \geq 3 \text{ prime.} \tag{3.18}$$

On the other hand, it is clear from the discussion around (3.12) that also these twining characters must be invariant under Γ^g, possibly up to a (different) multiplier system. In the context of Monstrous Moonshine, the McKay-Thompson series were Hauptmoduls for the corresponding genus zero congruence subgroups, and thus the McKay-Thompson series of the symmetric power theories could be written as a polynomial of the original McKay-Thompson series. This then leads to the replication formulae of Monstrous Moonshine (generalising directly the J-function replication identities of (2.23)).

In the current context, it appears that the twining characters are *not* of genus zero, but we still find remarkable replication identities that give yet another consistency check on our analysis (and indicate that the twining characters corresponding to 3B and 7A=7B have indeed good modular properties). Specifically, we have found the following identities for $p = 2$

$$\chi_{2\mathrm{A}}^{(2)}(\tau) = \chi_{1\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{2\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - 4 = \chi_{2\mathrm{A}}(\tau)^2 + 4 \tag{3.19}$$

$$\chi_{2\mathrm{B}}^{(2)}(\tau) = \chi_{1\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{2\mathrm{B}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) = \chi_{2\mathrm{B}}(\tau)^2 - 12 \tag{3.20}$$

$$\chi_{3\mathrm{A}}^{(2)}(\tau) = \chi_{3\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{3\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - 3 = \chi_{3\mathrm{A}}(\tau)^2 \tag{3.21}$$

$$\chi_{3\mathrm{B}}^{(2)}(\tau) = \chi_{3\mathrm{B}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{3\mathrm{B}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) = -\tfrac{1}{2}\,\chi_{3\mathrm{B}}(\tau)^2 + \tfrac{3}{2}\,T_{[12\mathrm{D}]}\left(\tfrac{\tau}{2}\right) \tag{3.22}$$

$$\chi_{4\mathrm{A}}^{(2)}(\tau) = \chi_{2\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{4\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) = -\chi_{4\mathrm{A}}(\tau)^2 + 2\,T_{[8\mathrm{E}]}\left(\tfrac{\tau}{2}\right) + 4 \tag{3.23}$$

$$\chi_{4\mathrm{B}}^{(2)}(\tau) = \chi_{2\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{4\mathrm{B}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - 2 = -\chi_{4\mathrm{B}}(\tau)^2 + 2\,T_{[8\mathrm{E}]}\left(\tfrac{\tau}{2}\right) - 4 \tag{3.24}$$

$$\chi_{4\mathrm{C}}^{(2)}(\tau) = \chi_{2\mathrm{B}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{4\mathrm{C}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) = -\tfrac{1}{2}\,\chi_{4\mathrm{C}}(\tau)^2 + \tfrac{3}{2}\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right)^2 \tag{3.25}$$

$$\chi_{5\mathrm{A}}^{(2)}(\tau) = \chi_{5\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{5\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - 2 = -\chi_{5\mathrm{A}}(\tau)^2 + 2\,T_{[20\mathrm{C}]}\left(\tfrac{\tau}{2}\right) - 4 \tag{3.26}$$

$$\chi_{6\mathrm{A}}^{(2)}(\tau) = \chi_{3\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{6\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - 1 = -\chi_{6\mathrm{A}}(\tau)^2 + 2\,T_{[12\mathrm{I}]}\left(\tfrac{\tau}{2}\right) \tag{3.27}$$

$$\chi_{7\mathrm{A}}^{(2)}(\tau) = \chi_{7\mathrm{A}}\left(2\tau, \tfrac{1}{2}\right) + \phi_{7\mathrm{A}}\left(\tfrac{\tau}{2}, \tfrac{1}{2}\right) - \tfrac{3}{2} = -2\chi_{7\mathrm{A}}(\tau)^2 + 3\,T_{[28\mathrm{B}]}\left(\tfrac{\tau}{2}\right) . \tag{3.28}$$

These identities imply recursion relations for the twining characters which one could use, say, to determine the twining character for 3B explicitly. Furthermore, since the McKay-Thompson series are known to have good modular transformation properties, the existence of these relations implies that the same must be true for the twining characters that appear here.

For $p = 3$ we have found the following explicit identities

$$\chi_{2\mathrm{A}}^{(3)}(\tau) = \chi_{2\mathrm{A}}(3\tau) + \sum_{l=0}^{2} \chi_{2\mathrm{A}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{2\mathrm{A}}(\tau)^3 + 12\,\chi_{2\mathrm{A}}(\tau) \tag{3.29}$$

$$\chi^{(3)}_{\mathrm{2B}}(\tau) = \chi_{\mathrm{2B}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{2B}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{2B}}(\tau)^3 - 12\,\chi_{\mathrm{2B}}(\tau) \tag{3.30}$$

$$\chi^{(3)}_{\mathrm{3A}}(\tau) = \chi_{\mathrm{1A}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{3A}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{3A}}(\tau)^3 + 6\,\chi_{\mathrm{3A}}(\tau) \tag{3.31}$$

$$\chi^{(3)}_{\mathrm{4A}}(\tau) = \chi_{\mathrm{4A}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{4A}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{4A}}(\tau)^3 - 12\,\chi_{\mathrm{4A}}(\tau) \tag{3.32}$$

$$\chi^{(3)}_{\mathrm{4B}}(\tau) = \chi_{\mathrm{4B}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{4B}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{4B}}(\tau)^3 \tag{3.33}$$

$$\chi^{(3)}_{\mathrm{4C}}(\tau) = \chi_{\mathrm{4C}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{4C}}\left(\tfrac{\tau+4l}{3}\right) = \tfrac{1}{4}\chi_{\mathrm{4C}}(\tau)^3 + \tfrac{3}{4}\chi_{\mathrm{4C}}(\tau)\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right)^2 - 6\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right) \tag{3.34}$$

$$\chi^{(3)}_{\mathrm{5A}}(\tau) = \chi_{\mathrm{5A}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{5A}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{5A}}(\tau)^3 \tag{3.35}$$

$$\chi^{(3)}_{\mathrm{6A}}(\tau) = \chi_{\mathrm{2A}}(3\tau) + \sum_{l=0}^{2} \chi_{\mathrm{6A}}\left(\tfrac{\tau+4l}{3}\right) = \chi_{\mathrm{6A}}(\tau)^3 - 6\,\chi_{\mathrm{6A}}(\tau)\ , \tag{3.36}$$

while for $p = 5$ we have found

$$\chi^{(5)}_{\mathrm{2A}}(\tau) = \chi_{\mathrm{2A}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{2A}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{2A}}(\tau)^5 + 20\,\chi_{\mathrm{2A}}(\tau)^3 + 70\,\chi_{\mathrm{2A}}(\tau) \tag{3.37}$$

$$\chi^{(5)}_{\mathrm{2B}}(\tau) = \chi_{\mathrm{2B}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{2B}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{2B}}(\tau)^5 - 20\,\chi_{\mathrm{2B}}(\tau)^3 + 70\,\chi_{\mathrm{2B}}(\tau) \tag{3.38}$$

$$\chi^{(5)}_{\mathrm{3A}}(\tau) = \chi_{\mathrm{3A}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{3A}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{3A}}(\tau)^5 + 10\,\chi_{\mathrm{3A}}(\tau)^3 + 15\,\chi_{\mathrm{3A}}(\tau) \tag{3.39}$$

$$\chi^{(5)}_{\mathrm{4A}}(\tau) = \chi_{\mathrm{4A}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{4A}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{4A}}(\tau)^5 - 20\,\chi_{\mathrm{4A}}(\tau)^3 + 30\,\chi_{\mathrm{4A}}(\tau) \tag{3.40}$$

$$\chi^{(5)}_{\mathrm{4B}}(\tau) = \chi_{\mathrm{4B}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{4B}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{4B}}(\tau)^5 - 10\,\chi_{\mathrm{4B}}(\tau) \tag{3.41}$$

$$\begin{aligned}\chi^{(5)}_{\mathrm{4C}}(\tau) = \chi_{\mathrm{4C}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{4C}}\left(\tfrac{\tau+4l}{5}\right) &= \tfrac{1}{16}\,\chi_{\mathrm{4C}}(\tau)^5 - \tfrac{1}{16}\chi_{\mathrm{4C}}(\tau)^3\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right)^2 \\ &+\chi_{\mathrm{4C}}(\tau)\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right)^4 - \tfrac{1}{2}\,\chi_{\mathrm{4C}}(\tau)^2\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right) - 4\,T_{[16\mathrm{d}]}\left(\tfrac{\tau}{4}\right)^3 - 2\,\chi_{\mathrm{4C}}(\tau)\end{aligned} \tag{3.42}$$

$$\chi^{(5)}_{\mathrm{5A}}(\tau) = \chi_{\mathrm{1A}}(5\tau) + \sum_{l=0}^{4} \chi_{\mathrm{5A}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{\mathrm{5A}}(\tau)^5 - 15\,\chi_{\mathrm{5A}}(\tau) \tag{3.43}$$

$$\chi_{6\mathrm{A}}^{(5)}(\tau) = \chi_{6\mathrm{A}}(5\tau) + \sum_{l=0}^{4} \chi_{6\mathrm{A}}\left(\tfrac{\tau+4l}{5}\right) = \chi_{6\mathrm{A}}(\tau)^5 - 10\,\chi_{6\mathrm{A}}(\tau)^3 - 5\,\chi_{6\mathrm{A}}(\tau)\ . \tag{3.44}$$

These are probably not the only identities that exist, but only those we have been able to find with our current partial understanding of the twining characters. Indeed, in order to be able to determine the higher order replication formulae, one needs to know the twining characters up to some fairly high level. Thus with our current understanding we can only check these identities for the twining characters given in (3.14).

4. Conclusions

In this paper we have provided strong evidence for the conjecture of Eguchi, Ooguri and Tachikawa [11] that the elliptic genus of K3 carries a natural action of the Mathieu group $\mathbb{M}_{24}$. In particular, we have shown that the elliptic genus with the insertion of a group element in $\mathbb{M}_{24}$ leads, in the NS-sector, to a twining character that possesses nice modular properties. By considering the twining characters of symmetric power theories we have furthermore shown that the twining characters satisfy beautiful replication identities similar to those appearing for the McKay-Thompson series in Monstrous Moonshine. While the analogy of the twining characters with the McKay-Thompson series is quite striking, there are also marked differences: in the current context the twining characters are not Hauptmoduls for a genus zero congruence subgroup, and hence the replication relations contain also 'inhomogeneous' terms (for example the term proportional to $T_{[12\mathrm{D}]}$ in (3.22)).

So far we have only worked out about half of the twining characters in detail. In order to get a more complete understanding of the Mathieu action on the K3 elliptic genus, it would be very desirable to find closed form expressions for all twining characters. Probably some more refined techniques (rather than just guessing and confirming the answer) will be necessary; in particular, the techniques developed by Bantay & Gannon [1, 2] should be useful for this.

The above analysis suggests that the space of $\mathcal{N}=2$ half-BPS states of K3 carries an action of the Mathieu group $\mathbb{M}_{24}$. It is believed that these $\mathcal{N}=2$ half-BPS states form a subset of the quarter-BPS states (with respect to $\mathcal{N}=4$), for which the spectrum generating algebra is the so-called BPS-algebra of Harvey & Moore [19, 7]. The above group action on the spectrum then suggests that the Mathieu group $\mathbb{M}_{24}$ should be (contained in) the automorphism group of that Borcherds algebra, in complete analogy to what happened for Monstrous Moonshine. It would be very interesting to explore this idea in more detail.

Acknowledgments

We thank Terry Gannon for useful communications and Daniel Persson for comments on the draft. The research of MRG is partially supported by a grant from the Swiss National Science Foundation, and the research of RV is supported by an INFN Fellowship.

Note added: As this paper was being finalised, a preprint appeared `arXiv:1005.5415` [4] that contains overlapping results with those of section 3.1 of the present paper.

A. Definitions

Our conventions for the Dedekind eta and the Jacobi theta functions are

$$\begin{aligned}
\eta(\tau) &= q^{\frac{1}{24}} \prod_{n=1}^{\infty}(1-q^n) \\
\vartheta_1(\tau,z) &= -iq^{\frac{1}{8}}y^{\frac{1}{2}} \prod_{n=1}^{\infty}(1-q^n)(1-yq^n)(1-y^{-1}q^{n-1}) \\
\vartheta_2(\tau,z) &= 2\,q^{\frac{1}{8}}\cos(\pi z) \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^n)(1+y^{-1}q^n) \\
\vartheta_3(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1+yq^{n-1/2})(1+y^{-1}q^{n-1/2}) \\
\vartheta_4(\tau,z) &= \prod_{n=1}^{\infty}(1-q^n)\,(1-yq^{n-1/2})(1-y^{-1}q^{n-1/2}) \quad .
\end{aligned} \tag{A.1}$$

Under modular transformations the ϑ and η functions transform as

$$\eta(\tau+1) = e^{\frac{2\pi i}{24}}\,\eta(\tau) \qquad \vartheta_2(\tau+1,z) = e^{\frac{2\pi i}{8}}\,\vartheta_2(\tau,z)\ , \tag{A.2}$$

$$\vartheta_3(\tau+1,z) = \vartheta_4(\tau,z) \qquad \vartheta_4(\tau+1,z) = \vartheta_3(\tau,z)\ , \tag{A.3}$$

as well as

$$\eta(-\tfrac{1}{\tau}) = (-i\tau)^{\frac{1}{2}}\,\eta(\tau) \qquad \vartheta_2(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_4(\tau,z)\ , \tag{A.4}$$

$$\vartheta_3(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_3(\tau,z) \qquad \vartheta_4(-\tfrac{1}{\tau},\tfrac{z}{\tau}) = (-i\tau)^{\frac{1}{2}}\,e^{\frac{i\pi z^2}{\tau}}\,\vartheta_2(\tau,z)\ . \tag{A.5}$$

The theta functions $\vartheta_a(\tau)$ are defined as $\vartheta_a(\tau) \equiv \vartheta_a(\tau, z=0)$.

A.1 McKay-Thompson series

For completeness we give here the first few terms of the McKay-Thompson series that appear in our analysis

$$T_{[8\mathrm{D}]} = q^{-1} + 4q + 2q^3 + 8q^5 - q^7 + \cdots \tag{A.6}$$

$$T_{[8\mathrm{E}]} = q^{-1} + 4q + 2q^3 - 8q^5 - q^7 + \cdots \tag{A.7}$$

$$T_{[8\mathrm{a}]} = q^{-1} - 20q - 62q^3 - 216q^5 - 641q^7 - 1636q^9 - \cdots \tag{A.8}$$

$$T_{[12\mathrm{D}]} = q^{-1} + 8q^2 + 28q^5 + 64q^8 + 134q^{11} + \cdots \tag{A.9}$$

$$T_{[12\mathrm{I}]} = q^{-1} + 2q + q^3 - 2q^7 - 2q^9 + 2q^{11} + \cdots \tag{A.10}$$

$$T_{[16\mathrm{A}]} = q^{-1} + 4q + 10q^3 + 24q^5 + 47q^7 + 84q^9 + \cdots \tag{A.11}$$

$$T_{[16\mathrm{B}]} = q^{-1} + 2q^3 - q^7 - 2q^{11} + 3q^{15} + 2q^{19} + \cdots \tag{A.12}$$

$$T_{[16\mathrm{b}]} = q^{-1} + 4q - 2q^3 + 8q^5 - q^7 + 20q^9 + \cdots \tag{A.13}$$

$$T_{[16\mathrm{d}]} = T_{[8\mathrm{D}]}(2\tau)^{1/2} = q^{-1} - 2q^3 - q^7 + 2q^{11} + \cdots \tag{A.14}$$

$$T_{[20\mathrm{C}]} = q^{-1} + q - 2q^2 + 2q^3 + 2q^4 - q^5 - 4q^7 + \cdots \tag{A.15}$$

$$T_{[24\mathrm{H}]} = q^{-1} + 2q + 5q^3 + 8q^5 + 14q^7 + 22q^9 + \cdots \tag{A.16}$$

$$T_{[24\mathrm{c}]} = q^{-1} - 2q + q^3 - 2q^7 + 2q^9 + 2q^{11} + \cdots \tag{A.17}$$

$$T_{[28\mathrm{B}]} = q^{-1} + 3q + 4q^2 + 9q^3 + 12q^4 + 15q^5 + 24q^6 + 39q^7 + \cdots \tag{A.18}$$

$$T_{[40\mathrm{a}]} = q^{-1} + 3q^3 + 4q^5 + 4q^7 + 4q^9 + 7q^{11} + \cdots \ , \tag{A.19}$$

see [15] and `http://www.research.att.com/ njas/sequences/` for more information about these series.

A.2 Twining characters for K3

Here we give the low order expansion of the remaining twining characters. Since the spectrum of the BPS states is real, the twining characters of conjugacy classes that only differ on conjugate representations agree. The remaining functions are therefore

$$\begin{aligned}\chi_{3\mathrm{B}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 4q^{\frac{1}{2}} + 4q + 4q^2 + 8q^{\frac{5}{2}} + 2q^3 + 8q^{\frac{7}{2}} + 12q^4 + 4q^{\frac{9}{2}} + 16q^5 + 16q^{\frac{11}{2}} \\ &+ 5q^6 + 26q^{\frac{13}{2}} + 21q^7 + \cdots\Big)\end{aligned} \tag{A.20}$$

$$\begin{aligned}\chi_{6\mathrm{B}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 4q^{\frac{1}{2}} + 8q + 16q^{\frac{3}{2}} + 32q^2 + 56q^{\frac{5}{2}} + 94q^3 + +152q^{\frac{7}{2}} + 240q^4 + 372q^{\frac{9}{2}} \\ &+ 560q^5 + 832q^{\frac{11}{2}} + 1197q^6 + 1594q^{\frac{13}{2}} + 1849q^7 + \cdots\Big)\end{aligned} \tag{A.21}$$

$$\begin{aligned}\chi_{7\mathrm{A}}(\tau) = \chi_{7\mathrm{B}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + q^{\frac{1}{2}} + \tfrac{9}{2}q + 8q^{\frac{3}{2}} + \tfrac{27}{2}q^2 + 23q^{\frac{5}{2}} + \tfrac{81}{2}q^3 + 68q^{\frac{7}{2}} + 104q^4 \\ &+ 154q^{\frac{9}{2}} + \tfrac{469}{2}q^5 + 352q^{\frac{11}{2}} + \tfrac{987}{2}q^6 + \tfrac{1293}{2}q^{\frac{13}{2}} + 751q^7 + \cdots\Big)\end{aligned} \tag{A.22}$$

$$\begin{aligned}\chi_{8\mathrm{A}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 2q^{\frac{1}{2}} + 6q + 12q^{\frac{3}{2}} + 23q^2 + 42q^{\frac{5}{2}} + 74q^3 + 124q^{\frac{7}{2}} + 203q^4 + 324q^{\frac{9}{2}} \\ &+ 502q^5 + 768q^{\frac{11}{2}} + 1141q^6 + 1567q^{\frac{13}{2}} + 1866q^7 + \cdots\Big)\end{aligned} \tag{A.23}$$

$$\begin{aligned}\chi_{10\mathrm{A}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 4q^{\frac{1}{2}} + 7q + 12q^{\frac{3}{2}} + 24q^2 + 40q^{\frac{5}{2}} + 63q^3 + 100q^{\frac{7}{2}} + 153q^4 + 232q^{\frac{9}{2}} \\ &+ 342q^5 + 492q^{\frac{11}{2}} + 692q^6 + 900q^{\frac{13}{2}} + 1018q^7 + \cdots\Big)\end{aligned} \tag{A.24}$$

$$\begin{aligned}\chi_{11\mathrm{A}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 2q^{\frac{1}{2}} + 4q + 4q^{\frac{3}{2}} + 8q^2 + 14q^{\frac{5}{2}} + 17q^3 + 24q^{\frac{7}{2}} + 37q^4 + 52q^{\frac{9}{2}} \\ &+ 68q^5 + 88q^{\frac{11}{2}} + 116q^6 + 141q^{\frac{13}{2}} + 147q^7 + \cdots\Big)\end{aligned} \tag{A.25}$$

$$\begin{aligned}\chi_{12\mathrm{A}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 4q^{\frac{1}{2}} + 7q + 12q^{\frac{3}{2}} + 26q^2 + 48q^{\frac{5}{2}} + 78q^3 + 128q^{\frac{7}{2}} + 211q^4 + 336q^{\frac{9}{2}} \\ &+ 516q^5 + 780q^{\frac{11}{2}} + 1157q^6 + 1592q^{\frac{13}{2}} + 1886q^7 + \cdots\Big)\end{aligned} \tag{A.26}$$

$$\begin{aligned}\chi_{14\mathrm{A}}(\tau) = \chi_{14\mathrm{B}}(\tau) = q^{-\frac{1}{4}}\Big(&1 + 3q^{\frac{1}{2}} + \tfrac{11}{2}q + 8q^{\frac{3}{2}} + \tfrac{33}{2}q^2 + 29q^{\frac{5}{2}} + \tfrac{87}{2}q^3 + 68q^{\frac{7}{2}} + 108q^4 \\ &+ 166q^{\frac{9}{2}} + \tfrac{487}{2}q^5 + 352q^{\frac{11}{2}} + \tfrac{1009}{2}q^6 + \tfrac{1335}{2}q^{\frac{13}{2}} + 761q^7 + \cdots\Big)\end{aligned} \tag{A.27}$$

Table 1: The character table of the Mathieu group. The rows correspond to the characters, while the columns describe the different conjugacy classes, numbered from 1 to 26 as in [11]. The second line gives the name of the conjugacy class that is used throughout the paper, where the number is the order of any element in the class. Where appropriate the classes of some powers are given in the third and fourth row, but only the non-trivial cases are stated. Finally, $e_p^\pm = (-1 \pm i\sqrt{p})/2$.

The McKay-Thompson series of Mathieu Moonshine modulo two

Thomas Creutzig*, Gerald Höhn† and Tsuyoshi Miezaki‡§

Abstract

In this note, we describe the parity of the coefficients of the McKay-Thompson series of Mathieu moonshine. As an application, we prove a conjecture of Cheng, Duncan and Harvey stated in connection with umbral moonshine for the case of Mathieu moonshine.

1 Introduction

In 2010, Eguchi, Ooguri, and Tachikawa [9] discovered a phenomenon connecting the Mathieu group M_{24} and the elliptic genus of a K3 surface. To describe their observation, we let $q = e^{2\pi i\tau}$ and consider the function

$$\begin{aligned}\Sigma(\tau) &= -8(\,\mu(1/2;\tau) + \mu(\tau/2;\tau) + \mu((\tau+1)/2;\tau))\\ &= q^{-\frac{1}{8}}(-2 + 90q + 462q^2 + 1540q^3 + 4554q^4 + 11592q^5 + 27830q^6 + \cdots)\end{aligned}$$

where

$$\begin{aligned}\mu(z;\tau) &= \frac{ie^{\pi iz}}{\theta_1(z;\tau)}\sum_{n\in\mathbb{Z}}(-1)^n\,\frac{q^{\frac{1}{2}n(n+1)}e^{2\pi inz}}{1-q^ne^{2\pi iz}},\\ \theta_1(z;\tau) &= \sum_{n=-\infty}^{\infty} q^{\frac{1}{2}(n+\frac{1}{2})^2}e^{2\pi i(n+\frac{1}{2})(z+\frac{1}{2})}.\end{aligned}$$

[§] This work was supported by JSPS KAKENHI Grant Number 22840003, 24740031.

The function $\Sigma(\tau)$ is a Mock modular form and counts the decomposition of the elliptic genus of a K3 surface into representations of the $\mathcal{N}$=4 Virasoro algebra.

The Mathieu moonshine phenomenon is that the first five coefficients appearing in the Fourier expansion of $\Sigma(\tau)$ divided by 2,

$$\{45, 231, 770, 2277, 5796\},$$

are equal to dimensions of irreducible representations of M_{24} and further coefficients can be written as simple sums of dimensions of the irreducible representations of M_{24}, for example $13915 = 3520 + 10395$. The reason for this mysterious phenomenon is still unknown.

This observation suggested the existence of a virtual graded M_{24}-module $K = \bigoplus_{n=-1}^{\infty} K_n \, q^{n/8}$ such that for $n \geq 0$ the K_n are honest M_{24}-representations. In analogy to the monstrous moonshine case [5], one can consider for an element g in the conjugacy class ℓX of M_{24} the so-called McKay-Thompson series

$$\Sigma_{\ell X}(\tau) = \sum_{n=-1}^{\infty} \mathrm{Tr}(g|K_n) \, q^{n/8}.$$

In [12, 7] (cf. also [1, 11, 2]), candidates for the 26 McKay-Thompson series for the Mathieu moonshine have been proposed. We note that the McKay-Thompson series for the M_{24} conjugacy classes in the pairs $(7A, 7B)$, $(14A, 14B)$, $(21A, 21B)$, $(15A, 15B)$ and $(23A, 23B)$ are equal to each other and we denote these cases shortly by ℓAB. We list in the appendix the 21 different McKay-Thompson series. Using explicit formulas, it can be shown that all the McKay-Thompson series have integer coefficients.

Elementary character theory [19] implies that the $\Sigma_{\ell X}(\tau)$ together uniquely determine the M_{24}-module K if it exists. Terry Gannon [13] showed that this is indeed the case.

Theorem 1.1 (Mathieu moonshine module)**.** *The McKay-Thompson series as in [12, 7] determine a virtual graded M_{24}-module $K = \bigoplus_{n=-1}^{\infty} K_n \, q^{n/8}$. For $n \geq 0$, the K_n are honest (and not only virtual) M_{24}-representations. Furthermore, K_n can be decomposed as a direct sum of M_{24}-representations of the form $\lambda \oplus \bar{\lambda}$ where λ is irreducible.*

This implies that if an irreducible representation λ is real, i.e. $\lambda \cong \bar{\lambda}$, then the multiplicity of an irreducible λ in K_n is even.

Unlike for the monstrous moonshine case where a vertex operator algebra structure was constructed in [10], there are yet no known underlying algebraic structures on the Mathieu moonshine module K.

To illustrate our main result, we consider the McKay-Thompson series for $7AB$:

$$\begin{aligned}\Sigma_{7AB}(\tau) =& \frac{1}{8}\,\left(\Sigma(\tau)\eta(\tau)^3 - 14\,\phi_2^{(7)}(\tau)\right)\Big/\,\eta(\tau)^3\\ =& -2q^{-1/8} - q^{7/8} + 4q^{31/8} - 2q^{47/8} + 2q^{55/8} - 3q^{63/8} + 6q^{87/8} - 6q^{103/8}\\ & -4q^{119/8} + 8q^{143/8} - 6q^{159/8} + 4q^{167/8} - 7q^{175/8} + 12q^{199/8} + \cdots .\end{aligned}$$

One observes that the coefficient of $q^{n/8}$ in $\Sigma_{7AB}(\tau)$ is odd if $n = 7m^2$, where m is odd. In general we show:

Theorem 1.2. *For a conjugacy class ℓX of M_{24}, the coefficient of $q^{n/8}$ in $\Sigma_{\ell X}(\tau)$ is odd if and only if $\ell X \in \{7AB, 14AB, 15AB, 23AB\}$ and $n = \ell m^2$, where m is odd, or $\ell X = 21AB$ and $n = \ell m^2$, where m is odd and not divisible by 3.*

For congruences of the Fourier coefficients of $\Sigma_{\ell X}(\tau)$ for other primes, we refer to the references [15, 17, 16]. One reason for considering the parity of the Fourier coefficients is that it explains the appearance of certain irreducible representations of M_{24}. The following conjecture was made in [3], which we state for the case of the Mathieu moonshine only.

Conjecture 1.1 ([3], Conj. 5.11)**.** *Let $n = \ell m^2 \equiv 7 \pmod 8$. Then the M_{24}-representation K_n determined by the coefficients of $q^{n/8}$ of the McKay-Thompson series contains the following conjugate pairs of irreducible representations:*

- *For $\ell = 7$, one of the pairs (χ_3, χ_4), (χ_{12}, χ_{13}) or (χ_{15}, χ_{16});*
- *for $\ell = 15$, the pair (χ_5, χ_6);*
- *for $\ell = 23$, the pair (χ_{10}, χ_{11}).*

Here, χ_i where $1 \leq i \leq 26$ denotes the i-th irreducible representation as listed in the ATLAS [4].

The paper is organized as follows. In Section 2, we study the cases $7AB$, $14AB$, $15AB$, $21AB$, $23AB$. In Section 3, we study the remaining cases. In the final section, we use Theorem 1.2 to prove Conjecture 1.1.

Acknowledgments. The first two authors like to thank the Hausdorff Research Institute of Mathematics for the hospitality received during their stay for the Mathematical Physics trimester program. We also like to thank M. Cheng, T. Gannon and S. Hohenegger for discussions. Finally, we are grateful to the referees for the suggested improvements of the exposition.

2 The non-even cases

In this section, we prove Theorem 1.2 for the cases $7AB$, $14AB$, $15AB$, $21AB$ and $23AB$.

The strategy is to obtain the parity properties of $\Sigma_{\ell X}(\tau)$ from the parity properties of a modular form for a group $\Gamma_0(N)$ which in turn can be proven by an application of Sturm's theorem [20]. The theorem allows to obtain a divisibility property of the Fourier coefficients of a modular form of weight k for $\Gamma_0(N)$ by veryfing this property only for the first n coefficients where n is an explicit given bound depending only on N and k,

$$n \geq \frac{k}{12}[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)].$$

We let

$$\eta(\tau) = q^{1/24} \prod_{m=1}^{\infty} (1 - q^m)$$

be the Dedekind η-function and consider for $N \geq 2$ the Eisenstein series

$$\begin{aligned} \phi_2^{(N)}(\tau) &= \frac{24}{N-1}\, q\, \frac{d}{dq} \log\left(\frac{\eta(N\tau)}{\eta(\tau)}\right) \\ &= 1 + \frac{24}{N-1} \sum_{k=1}^{\infty} \sigma_1(k)(q^k - Nq^{Nk}) \end{aligned} \tag{1}$$

of weight 2 for $\Gamma_0(N)$.

Proof of Theorem 1.2 for the case $7AB$. Define the function $f_m(\tau)$ as follows:

$$f_m(\tau) = \frac{1}{4}\Big(\vartheta_3(\frac{m\tau}{8}) - \vartheta_4(\frac{m\tau}{8})\Big)$$

where $\vartheta_3(\tau) = 1 + \sum_{m=1}^{\infty} 2q^{m^2}$ and $\vartheta_4(\tau) = 1 + \sum_{m=1}^{\infty} 2(-q)^{m^2}$. Then

$$f_7(\tau) = \frac{1}{4}\Big(\vartheta_3(\frac{7\tau}{8}) - \vartheta_4(\frac{7\tau}{8})\Big) = q^{7/8} + q^{63/8} + q^{175/8} + q^{343/8} + \cdots$$

We call $f_7(\tau)$ the "parity function."

We have to show that all coefficients of $\Sigma_{7AB}(\tau) + f_7(\tau)$ are even since the coefficient of $q^{n/8}$ in $f_7(\tau)$ is odd if and only if $n = 7m^2$, where m is odd. This follows if all coefficients of $(\Sigma_{7AB}(\tau) + f_7(\tau))\eta(\tau)^3$ are even since $\eta(\tau)^{-3}$ has integral coefficients.

Let

$$E_2(\tau) = 1 - 24\sum_{m=1}^{\infty} \sigma_1(m)q^m.$$

By [6, p. 43, Example 4], we have

$$\Sigma(\tau) = -2\,\left(E_2(\tau) + 24\sum_{n=1}^{\infty}\frac{(-1)^n n q^{\frac{1}{2}n(n+1)}}{1-q^n}\right)\Big/\,\eta(\tau)^3\,. \tag{2}$$

Thus

$$\begin{aligned}(\Sigma_{7AB}(\tau) + f_7(\tau))\eta(\tau)^3 &= \frac{1}{8}\left(\Sigma(\tau)\eta(\tau)^3 - 14\,\phi_2^{(7)}(\tau)\right) + \eta(\tau)^3 f_7(\tau)\\ &= -\frac{1}{4}\Big(E_2(\tau) + 24\sum_{n=1}^{\infty}\frac{(-1)^n n q^{\frac{1}{2}n(n+1)}}{1-q^n} + 7\phi_2^{(7)}(\tau)\Big) + \eta(\tau)^3 f_7(\tau).\end{aligned}$$

First, we observe that the constant term is even. Since all coefficients, except for the constant term, of the function

$$-\frac{1}{4}\Big(E_2(\tau) + 24\sum_{n=1}^{\infty}\frac{(-1)^n n q^{\frac{1}{2}n(n+1)}}{1-q^n}\Big)$$

are even, it is enough to show that the coefficients of the following function, again except for the constant term,

$$-\frac{7}{4}\phi_2^{(7)}(\tau) + \eta(\tau)^3 f_7(\tau) = -\frac{7}{4} - 6q - 24q^2 - 28q^3 - 44q^4 - 42q^5 + \cdots\,.$$

are even.

Define the "correction function"

$$\frac{7}{4}\vartheta_3(\tau)^4 = \frac{7}{4} + 14q + 42q^2 + 56q^3 + 42q^4 + 84q^5 + \cdots .$$

The coefficients of $\frac{7}{4}\vartheta_3(\tau)^4$ without the constant term are even, hence it is enough to show that the coefficients of the function

$$-\frac{7}{4}\phi_2^{(7)}(\tau) + \eta(\tau)^3 f_7(\tau) + \frac{7}{4}\vartheta_3(\tau)^4 = 8q + 18q^2 + 28q^3 - 2q^4 + 42q^5 + \cdots$$

are even. We are going to prove this using Sturm's theorem. The theta functions $\vartheta_3(\tau)$ and $\vartheta_4(\tau)$ can be expressed as a quotient of η-functions, namely

$$\vartheta_3(\tau) = \frac{\eta(2\tau)^5}{\eta(\tau)^2\eta(4\tau)^2} \qquad \text{and} \qquad \vartheta_4(\tau) = \frac{\eta(\tau)^2}{\eta(2\tau)}.$$

It follows using [18, Theorem 1.64] that $\eta(8\tau)^3 f_7(8\tau)$ is a modular form of weight 2 for $\Gamma_0(448)$ and hence

$$\begin{aligned}\sum_{m=1}^{\infty} a_{7AB}(m)q^m &:= -\frac{7}{4}\phi_2^{(7)}(8\tau) + \eta(8\tau)^3 f_7(8\tau) + \frac{7}{4}\vartheta_3(8\tau)^4 \\ &= 8q^8 + 18q^{16} + 28q^{24} + \cdots\end{aligned}$$

is also a modular form of weight 2 for $\Gamma_0(448)$. Using Sturm's theorem [20] (see also [18, Theorem 2.58]) and the fact that $[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(448)] = 768$, the computer verification that $a_{7AB}(m) \equiv 0 \pmod 2$ for $m \leq 129$ shows $a_{7AB}(m) \equiv 0 \pmod 2$ for all m.

This completes the proof of the case $7AB$. ☐

Since the other cases can be handled in complete analogy, we collect the relevant information in Table 1. For the definition of $\Sigma_{23AB}(\tau)$ in Appendix A, we use functions $f_{23,1}(\tau)$ and $f_{23,2}(\tau)$ which are modular forms for $\Gamma_0(23)$, explicitly given in [8, Appendix A.1].

3 The even cases

In this section, we prove that all coefficients of the McKay-Thompson series for the remaining conjugacy classes of M_{24} are divisible by two.

Table 1: Data for the proofs in Section 2

ℓX	parity function	correction function	Γ	$[\mathrm{SL}_2(\mathbb{Z}) : \Gamma]$	Sturm bound
$7AB$	$f_7(\tau)$	$\frac{7}{4}\vartheta_3(\tau)^4$	$\Gamma_0(448)$	768	129
$14AB$	$f_7(\tau)$	$\frac{23}{12}\phi_2^{(2)}(\tau)$	$\Gamma_0(448)$	768	129
$15AB$	$f_{15}(\tau)$	$\frac{23}{12}\phi_2^{(2)}(\tau)$	$\Gamma_0(960)$	2304	385
$21AB$	$f_7(\tau)$-$f_{63}(\tau)$	$2\vartheta_3(\tau)^4$	$\Gamma_0(4032)$	9216	1537
$23AB$	$f_{23}(\tau)$	$\frac{23}{12}\phi_2^{(2)}(\tau)$	$\Gamma_0(1472)$	2304	385

We remark that the case $1A$ is clear since $\Sigma_{1A}(\tau) = \Sigma(\tau)$ and equation (2). It is trivial to see that for the cases $2B$, $3B$, $4A$, $4C$, $6B$, $10A$, $12A$, $12B$, the coefficients of $\Sigma_{\ell X}(\tau)$ are even because $\Sigma_{\ell X}(\tau)$ is -2 times an η-product (see the appendix).

3.1 The cases $2A$, $3A$, $4B$, $5A$, $6A$, $8A$

We give the detailed proof for the case of $2A$.

Proof. The McKay-Thompson series for $2A$ is

$$\begin{aligned}\Sigma_{2A}(\tau) &= \frac{1}{3}\left(\Sigma(\tau)\eta(\tau)^3 - 4\phi_2^{(2)}(\tau)\right)\Big/\,\eta(\tau)^3\\ &= -2q^{-1/8} - 6q^{7/8} + 14q^{15/8} - 28q^{23/8} + 42q^{31/8} + \cdots .\end{aligned}$$

The coefficients of $\Sigma(\tau)\eta(\tau)^3$, except for the constant term, are divisible by 24 (cf. (2)). Moreover, also the coefficients of $\phi_2^{(2)}(\tau)$, again except for the constant term, are divisible by 24. The constant term of the function $\Sigma(\tau)\eta(\tau)^3 - 4\phi_2^{(2)}(\tau)$ is 6. Therefore, the coefficients of $\Sigma_{2A}(\tau)$ are divisible by two. □

The proof for the other cases is analogous. The relevant information can be read off from Table 2 together with the appendix.

3.2 The case $11A$

Finally, it remains to show that the Fourier coefficients of the McKay-Thompson series for the case $11A$ are divisible by two. Because of the extra term

Table 2: Data for the proofs in Section 3.1

ℓX	N	divisor of $\phi_2^{(N)}(\tau)-1$
$2A$	2	24
$3A$	3	12
$5A$	5	6
$4B$	2, 4	24, 8
$8A$	4, 8	8, 24/7
$6A$	2, 3, 6	24, 12, 24/5

$\frac{264}{5}(\eta(\tau)\eta(11\tau))^2$ in $\Sigma_{11A}(\tau)$, it is not obvious that the coefficients except for the constant term in the numerator for $\Sigma_{11A}(\tau)$ as given in the appendix are divisible by 24. Therefore, we proceed similar to the cases in Section 3.1.

Proof. The McKay-Thompson series for $11A$ is

$$\Sigma_{11A}(\tau)=\frac{1}{12}\left(\Sigma(\tau)\eta(\tau)^3-22\,\phi_2^{(11)}(\tau)+\frac{264}{5}(\eta(\tau)\eta(11\tau))^2\right)\Big/\;\eta(\tau)^3\,.$$

The coefficients of $\Sigma(\tau)\eta(\tau)^3$, except for the constant term are divisible by 24. We need to prove that the coefficients of the function:

$$22\,\phi_2^{(11)}(\tau)-\frac{264}{5}(\eta(\tau)\eta(11\tau))^2=22+264q^2+264q^3+264q^4+\cdots$$

are also (except for the constant term) divisible by 24. The coefficients of $22\phi_2^{(2)}(\tau)$ (except for the constant term) are divisible by 24, hence it is enough to show that the coefficients of the function

$$\begin{aligned}\sum_{m=1}^{\infty}a_{11A}(m)q^m &:= 22\phi_2^{(11)}(\tau)-\frac{264}{5}(\eta(\tau)\eta(11\tau))^2-22\,\phi_2^{(2)}(\tau)\\ &= -528q-264q^2-1848q^3-264q^4-2904q^5-1584q^6-3696q^7+\cdots\end{aligned}$$

are divisible by 24. Note that this function is a modular form for $\Gamma_0(22)$ [14, p. 130, Proposition 19]. Using Sturm's theorem [18, Theorem 2.58] again and the fact that $[\mathrm{SL}_2(\mathbb{Z}):\Gamma_0(22)]=36$, the verification that $a_{11A}(m)\equiv 0 \pmod{24}$ for $m\leq 7$ shows $a_{11A}(m)\equiv 0 \pmod{24}$ for all m. Therefore, the coefficients of $\Sigma_{11A}(\tau)$ are divisible by two. ☐

Sections 2 and 3 together prove Theorem 1.2.

4 Multiplicities of Irreducibles

Recall that χ_i denotes the i-th irreducible M_{24}-representation as in [4]. We will use Theorem 1.2 to prove the following result about the multiplicities of the M_{24}-representation $\lambda \oplus \bar{\lambda}$ with irreducible λ inside the Mathieu moonshine module constituents K_n:

Theorem 4.1. *Let $n = \ell m^2 \equiv 7 \pmod 8$ and let K_n be the degree n-part of the Mathieu moonshine module K. Then the following numbers are odd (and therefore positive):*

- *For $\ell = 7$, the multiplicity of $\chi_3 \oplus \chi_4$ in K_n plus the multiplicity of $\chi_{12} \oplus \chi_{13}$ in K_n;*
- *for $\ell = 7$ and m divisible by 3, the multiplicity of $\chi_{15} \oplus \chi_{16}$ in K_n;*
- *for $\ell = 15$, the multiplicity of $\chi_5 \oplus \chi_6$ in K_n;*
- *for $\ell = 23$, the multiplicity of $\chi_{10} \oplus \chi_{11}$ in K_n.*

Proof. Let

$$K_n = \bigoplus_{i=1}^{26} m_{\chi_i} \chi_i \tag{3}$$

be the decomposition of the M_{24}-representation K_n into its irreducible constituents, i.e. m_{χ_i} is the multiplicity in which χ_i occurs in K_n. Taking on both sides of (3) the trace for an element $g \in M_{24}$ we have

$$\mathrm{Tr}(g|K_n) = \sum_{i=1}^{26} m_{\chi_i} \, \mathrm{Tr}(g|\chi_i) \tag{4}$$

and $\mathrm{Tr}(g|K_n)$ is the coefficient of $q^{n/8}$ in $\Sigma_{\ell X}(\tau)$ with ℓX the conjugacy class of g. We note that if K_n is non-zero then n is odd, i.e. we only need to consider the cases $n = \ell m^2$ with m odd.

First, we consider the cases $\ell = 15$ and $\ell = 23$ and let g be an element of type $15A$ or $23A$, respectively. If n is of the form ℓm^2 with m odd, the left-hand side of (4) is odd by Theorem 1.2. For the right-hand side an inspection of the character table of M_{24} [4] shows that if $\lambda \neq \bar{\lambda}$ one has that $\mathrm{Tr}(g|\lambda) = \mathrm{Tr}(g|\bar{\lambda})$ is integral unless $(\lambda, \bar{\lambda}) = (\chi_5, \chi_6)$ or (χ_{10}, χ_{11}), respectively, in which case $\mathrm{Tr}(g|\lambda + \bar{\lambda}) = -1$. Using Theorem 1.1, it follows that $m_\lambda = m_{\bar{\lambda}}$ has then to be odd.

For the cases $\ell = 7$, we let g be an element of type $7A$. Here, only the characters (χ_3, χ_4) or (χ_{12}, χ_{13}) can provide an odd contribution to the right-hand side of (4) and so in total an odd number of those pairs has to appear. For m divisible by 3, we take in addition an element g of type $21A$. Here (χ_3, χ_4), (χ_{12}, χ_{13}) and (χ_{15}, χ_{16}) provide an odd contribution. Since the total number of pairs of type (χ_3, χ_4) and (χ_{12}, χ_{13}) is odd and by Theorem 1.2 the left-hand side of (4) is even, it follows that the number of pairs (χ_{15}, χ_{16}) is odd, too. $\square$

It is clear that Theorem 4.1 implies Conjecture 1.1.

The argument in the proof can also be applied to the elements g of type ℓX as studied in Section 3. One directly recovers Theorem 1.2 for those cases. However, Theorem 1.1 as stated is a refinement which uses parts of our original arguments in its proof.

We remark that it is likely that the methods in proving Theorem 1.2 and Theorem 4.1 could also be applied to the other cases of umbral moonshine.

A McKay-Thompson series

We list all McKay-Thompson series using the ATLAS [4] names for the conjugacy classes of M_{24}. We refer to Section 2 for the functions used.

$$
\begin{aligned}
\mathbf{1A}: &\quad \Sigma_{1A}(\tau) = \Sigma(\tau) \\

0. Introduction et notations

Les objets concernés par cet article sont essentiellement les solides platoniciens, i. e. les polyèdres réguliers de $\mathbb{R}^3$. La première démonstration du fait qu'ils sont au nombre de cinq (tétraèdre, octaèdre, cube, dodecaèdre et icosaèdre) est attribuée à Théétète ([P], [E]), qui a aussi prouvé qu'on peut les inscrire dans une sphère. Un groupe de rotations R qui laisse fixe un tel polyèdre est appelé groupe polyédral pur, et peut être considéré comme sous-groupe

© Gauthier-Villars

de PGL(2, $\mathbb{C}$), moyennant l'identification de la sphère S^2 avec la droite projective complexe $\mathbb{P}^1$. Le groupe G, image inverse de R par l'homomorphisme canonique de SL(2, $\mathbb{C}$) sur PGL(2, $\mathbb{C}$), est appelé groupe binaire polyédral. On trouve ainsi (à isomorphisme près) trois sous-groupes finis de SL(2, $\mathbb{C}$), car le cube et le dodecaèdre sont respectivement duaux de l'octaèdre et de l'icosaèdre par la dualité qui associe à un polyèdre celui dont les sommets sont les centres de ses faces (le tétraèdre est auto-dual), et deux polyèdres duaux ont le même groupe polyédral pur associé. Pour obtenir tous les sous-groupes finis de SL(2, $\mathbb{C}$) (à conjugaison près) il faut ajouter deux familles dénombrables : les groupes cycliques et les groupes diédraux binaires (*voir* par exemple [K] ou [D]); pour les groupes diédraux on peut aussi considérer les « groupes diédraux purs » comme étant les groupes de rotations de certains polyèdres appelés dièdres.

Soit G, donc, un sous-groupe fini de SL(2, $\mathbb{C}$), $G \neq \{1\}$; il agit naturellement sur $V = \mathbb{C}^2$; il a comme seul point fixe l'origine 0 et il agit librement sur $V - \{0\}$.

Posons $S = V/G$; notons $p : V \to S$ le morphisme de passage au quotient. La surface S a un point singulier isolé qui est un point double rationnel ([A], [Br], [D], [K]) et cette construction permet d'obtenir ainsi tous les points doubles rationnels [Br].

Soit $q : \tilde{S} \to S$ une désingularisation minimale de S, $D \subset \tilde{S}$ le diviseur exceptionnel; notons $\mathrm{Irr}(D) = \{d_1, \ldots, d_r\}$ l'ensemble des composantes irréductibles de D.

On peut associer à G un diagramme de Dynkin $\Gamma(G)$ en prenant le graphe dual de la résolution $\tilde{S}$, graphe dont les sommets sont en bijection avec Irr(D), et dont les arêtes joignant deux sommets représentent les points d'intersection des composantes de D correspondantes. Suivant le cas, le diagramme est donné par le tableau suivant :

G	$\lvert G \rvert$			$\Gamma(G)$
cyclique	$n+1$	$\mathbf{A}_n$:		
diédral binaire	$4(n-2)$	$\mathbf{D}_n$:		(n sommets, $n \geqq 1$)
tétraédral binaire	24	$\mathbf{E}_6$:		(n sommets, $n \geqq 4$)
octaédral binaire	48	$\mathbf{E}_7$:		
icosaédral binaire	120	$\mathbf{E}_8$:		

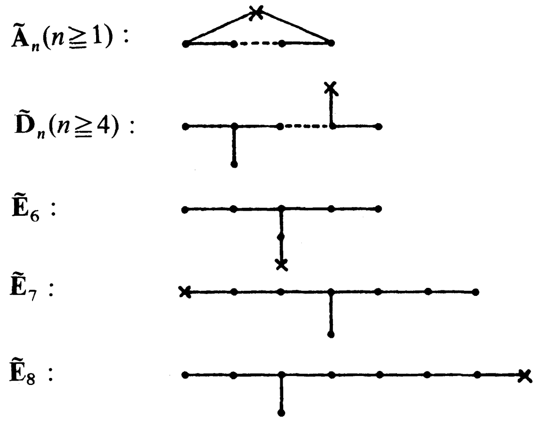
Pour tout sous-groupe fini G de SL(2, $\mathbb{C}$) on appelle $\Gamma(G)$ le type de G.

Considérons, par ailleurs, l'ensemble des classes d'équivalence de représentations non triviales de G : $\mathrm{Irr}(G)=\{\rho_1,\ldots,\rho_n\}$. Notons c la représentation canonique de G dans $\mathbb{C}^2$ donnée par l'inclusion $G \hookrightarrow SL(2, \mathbb{C})$, et ρ_0 la représentation triviale de degré 1. On définit la $(r+1)\times(r+1)$ matrice $C=((a_{ij}))$ par la formule de décomposition :

$$c\otimes\rho_i=\sum a_{ij}\,\rho_j,$$

où a_{ij} dénote la multiplicité de ρ_j dans $c\otimes\rho_i$.

J. McKay a remarqué que la matrice 2 Id – C (où Id est la matrice d'identité) est la matrice de Cartan du diagramme de Dynkin complété $\tilde{\Gamma}(G)$ de $\Gamma(G)$ ([M], Appendix III de [S1]). Du point de vue des représentations de groupes cette propriété a été analysée par J. Steinberg [St]. Ces diagrammes de Dykin complétés sont donc les suivants :



où on a indiqué par une croix le sommet ajouté.

La remarque de McKay permet de définir de façon purement combinatoire une bijection entre l'ensemble des classes d'équivalence de représentations irréductibles de G et l'ensemble de sommets de $\tilde{\Gamma}(G)$, qui induit une bijection entre le graphe de Irr(G) et celui de Irr(D) (en faisant correspondre à ρ_0 le sommet ajouté), bijection définie à automorphisme de diagramme près.

Cette bijection possède la propriété suivante : les degrés des représentations appartenant à Irr(G) coïncident avec les coefficients de la plus grande racine dans le système de racines de $\Gamma(G)$. Cette propriété peut être énoncée d'une autre façon, en considérant le cycle fondamental $\mathscr{Z}=\sum n_i d_i$ de $\tilde{S}$ (*voir* la définition dans [A]). Le cycle fondamental est (pour les singularités rationnelles) le cycle divisoriel défini par l'idéal (localement principal) $q^*(\mathscr{M}_S)$, avec $\mathscr{M}_S$ l'idéal maximal du point singulier. Soit $\mathscr{H}$ une section hyperplane générale de S contenant le point singulier. Alors l'image inverse $q^*(\mathscr{H})$ s'écrit $q^*(\mathscr{H})=\mathscr{Z}+\mathscr{T}$, où $\mathscr{T}$ est la transformée stricte et $\mathscr{Z}$ la partie de $q^*(\mathscr{H})$ à support dans D. On peut faire correspondre à $\mathscr{T}$ le sommet ajouté dans $\tilde{\Gamma}(G)$; on vérifie que les arêtes ajoutées correspondent aussi aux points d'intersection de $\mathscr{T}$ avec D. En ces termes, la bijection mentionnée associe à ρ_0 la transformée stricte $\mathscr{T}$ et à chaque $\rho\in\mathrm{Irr}(G)$ une composante $d\in\mathrm{Irr}(D)$ de telle sorte que le degré de ρ coïncide avec la multiplicité de d dans le cycle fondamental $\mathscr{Z}$.

Nous présentons ici une description géométrique de la correspondanxe de McKay. Plus précisément, à toute représentation irréductible non triviale ρ de G, on associe un fibré vectoriel $\mathscr{F}_\rho$ sur $\tilde{\mathscr{S}}$ (où $\tilde{\mathscr{S}}$ est la désingularisation minimale du germe $\mathscr{S}$ de la surface S au point singulier), fibré vectoriel dont la classe de Chern $c_1(\mathscr{F}_\rho)$ est un élément de la base canonique de $\operatorname{Pic}(\tilde{\mathscr{S}})$ en bijection avec les sommets de Irr(D) (¹).

1. Résultats préliminaires : $K(\tilde{\mathscr{S}})$ et R(G)

1.1. Soient $\mathscr{S}$ le germe de S au point singulier, $q : \tilde{\mathscr{S}} \to \mathscr{S}$ une résolution minimale, $\operatorname{Pic}(\tilde{\mathscr{S}})$ le groupe de Picard de $\tilde{\mathscr{S}}$ des classes d'isomorphisme de fibrés de rang 1 ou de $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules inversibles, et $\operatorname{Irr}(D) = \{ d_1, \ldots, d_r \}$ l'ensemble des composantes irréductibles du diviseur exceptionnel $D \subset \tilde{\mathscr{S}}$. Pour chaque $d \in \operatorname{Irr}(D)$, notons e_d la classe de $\mathcal{O}_{\tilde{\mathscr{S}}}(d)$ dans $\operatorname{Pic}(\tilde{\mathscr{S}})$, et $\operatorname{Pic}_D(\tilde{\mathscr{S}})$ le sous-groupe de $\operatorname{Pic}(\tilde{\mathscr{S}})$ engendré par les e_d. Soit $\operatorname{Pic}_D(\tilde{\mathscr{S}})^*$ le dual de $\operatorname{Pic}_D(\tilde{\mathscr{S}})$, et notons $\delta : \operatorname{Pic}(\tilde{\mathscr{S}}) \to \operatorname{Pic}_D(\tilde{\mathscr{S}})^*$ l'homomorphisme défini par la forme intersection de $\operatorname{Pic}(\tilde{\mathscr{S}})$. On sait que δ est un isomorphisme, car $\mathscr{S}$ est une singularité rationnelle [A]. Notons $\{ b_d \mid d \in \operatorname{Irr}(D) \}$ la base de $\operatorname{Pic}(\tilde{\mathscr{S}})$ transportée par δ^{-1} de la base duale de $\{ e_d \mid d \in \operatorname{Irr}(D) \}$. La matrice de l'injection canonique $\operatorname{Pic}_D(\tilde{\mathscr{S}}) \hookrightarrow \operatorname{Pic}(\tilde{\mathscr{S}})$ dans les bases $\{ e_d \}$ et $\{ b_d \}$ respectivement, est appelée la matrice d'intersection.

On considère d'autre part l'anneau de Grothendieck $K(\tilde{\mathscr{S}})$ des classes de $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules cohérents, et on note $K_D(\tilde{\mathscr{S}})$ le sous-groupe engendré par les classes de $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules à support dans D; $K_D(\tilde{\mathscr{S}})$ est un idéal de $K(\tilde{\mathscr{S}})$. Pour tout $\mathcal{O}_{\tilde{\mathscr{S}}}$-module cohérent M notons [M] sa classe dans $K(\tilde{\mathscr{S}})$, et pour tout $d \in \operatorname{Irr}(D)$ posons $[d] = [\mathcal{O}_d]$. Finalement notons $rg : K(\tilde{\mathscr{S}}) \to \mathbb{Z}$ [resp. $c_1 : K(\tilde{\mathscr{S}}) \to \operatorname{Pic}(\tilde{\mathscr{S}})$] l'application induite par celle qui associe à un $\mathcal{O}_{\tilde{\mathscr{S}}}$-module cohérent son rang (resp. sa première classe de Chern).

Avec les notations précédentes on a :

1.2. PROPOSITION. — (i) *L'application* $\varphi : K(\tilde{\mathscr{S}}) \to \mathbb{Z} \oplus \operatorname{Pic}(\tilde{\mathscr{S}})$ *définie par* $x \mapsto (rg(x), c_1(x))$ *est un isomorphisme de groupes commutatifs. Pour tout* $L \in \operatorname{Pic}(\tilde{\mathscr{S}})$ *on a* $\varphi([L]) = (1, L)$.

(ii) *Le noyau de* $rg : K(\tilde{\mathscr{S}}) \to \mathbb{Z}$ *est un idéal de carré nul.*

(iii) *L'image par* φ *de* $K_D(\tilde{\mathscr{S}})$ *est* $\operatorname{Pic}_D(\tilde{\mathscr{S}})$. *Pour tout* $d \in \operatorname{Irr}(D)$ *on a* $\varphi([d]) = (0, e_d)$.

Démonstration. — Si $L \in \operatorname{Pic}(\tilde{\mathscr{S}})$, l'égalité $\varphi([L]) = (1, L)$ résulte de la définition de φ; par suite, si $n \in \mathbb{Z}$ on a :

$$\varphi((n-1)\mathbf{1} + [L]) = (n, L),$$

d'où la surjectivité de φ.

L'injectivité résulte du fait que le noyau est le sous-groupe $K_2(\tilde{\mathscr{S}}) \subset K(\tilde{\mathscr{S}})$ des classes de modules à support de codimension ≧ 2 dont on vérifie immédiatement qu'il est nul; ceci

---

(¹) Ces résultats ont été annoncés en [G-V]. H. Knörrer nous a fait parvenir une lettre en décembre 1981, où il propose une démonstration différente, trouvée indépendamment.

montre aussi (ii). Finalement, soit $d \in \mathrm{Irr}(d)$. On a la suite exacte :

$$0 \to \mathcal{O}_{\tilde{\mathcal{S}}}(-d) \to \mathcal{O}_{\tilde{\mathcal{S}}} \to \mathcal{O}_d \to 0,$$

d'où (iii).

1.3. Soit R(G) l'anneau des représentations de G. Si ρ est une représentation de G, on note $\rho^{\vee}$ la représentation duale ou contragrédiente de ρ.

Notons $\mathcal{V}$ le germe de V à l'origine 0.

On considère l'anneau de Grothendieck $\mathrm{K}^{\mathrm{G}}(\mathcal{V})$ des classes de $\mathcal{O}_{\mathcal{V}}$-modules cohérents G-équivariants, et le sous-groupe $\mathrm{K}^{\mathrm{G}}(0)$ de $\mathrm{K}^{\mathrm{G}}(\mathcal{V})$ de classes de $\mathcal{O}_{\mathcal{V}}$-modules à support dans 0.

1.4. Proposition. — (i) *L'application qui à une représentation* ρ *de* G *dans un* ℂ*-espace vectoriel* E_ρ *associe le* $\mathcal{O}_{\mathcal{V}}$*-module* G*-équivariant* $\mathcal{O}_{\mathcal{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^{\vee}}$ *induit un isomorphisme d'anneaux* $\mathrm{R}(\mathrm{G}) \xrightarrow{\sim} \mathrm{K}^{\mathrm{G}}(\mathcal{V})$ *qui permet d'identifier ces anneaux.*

(ii) *Soit* $\mathcal{M}_{\mathcal{V}}$ *l'idéal maximal en l'origine* 0 *de* $\mathcal{V}$. *La classe* $[\mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}}]$ *dans* $\mathrm{K}^{\mathrm{G}}(\mathcal{V}) = \mathrm{R}(\mathrm{G})$ *est* $2-c$. *L'image de* $\mathrm{K}^{\mathrm{G}}(0)$ *dans* $\mathrm{K}^{\mathrm{G}}(\mathcal{V}) = \mathrm{R}(\mathrm{G})$ *est l'idéal engendré par* $2-c$.

(iii) *L'idéal* $(2-c)\,\mathrm{R}(\mathrm{G})$ *est un* ℤ*-module libre engendré par* $(2-c)\,\rho$, $\rho \in \mathrm{Irr}(\mathrm{G})$. *On a la relation :*

$$2-c = \sum_{\rho \in \mathrm{Irr}(\mathrm{G})} (\deg \rho).(c-2)\,\rho.$$

Démonstration. — L'affirmation de (i) résulte du fait que l'homomorphisme inverse est celui induit par l'application qui à un $\mathcal{O}_{\mathcal{V}}$-module G-équivariant M associe l'élément de R(G) défini par $\sum_i (-1)^i [\mathrm{Tor}_i^{\mathcal{O}_{\mathcal{V}}}(\mathrm{M}, \mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}})]$.

Pour démontrer l'égalité $[\mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}}] = 2-c$, on considère la suite exacte de Koszul de $\mathcal{O}_{\mathcal{V}}$-modules G-équivariants :

$$0 \to \Lambda^2 \mathrm{T}_{\mathcal{V}} \to \mathrm{T}_{\mathcal{V}} \to \mathcal{O}_{\mathcal{V}} \to \mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}} \to 0,$$

où $\mathrm{T}_{\mathcal{V}}$ est le faisceau tangent de $\mathcal{V}$.

Or $\mathrm{T}_{\mathcal{V}} \cong \mathcal{O}_{\mathcal{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_c$ car c est par définition la représentation canonique de G, représentation qui est auto-dual (i.e. $c = c^{\vee}$); et d'autre part $\Lambda^2 \mathrm{T}_{\mathcal{V}} \cong \mathcal{O}_{\mathcal{V}}$ car on a $\mathrm{G} \subset \mathrm{SL}(2, \mathbb{C})$. Par conséquent la suite exacte précédente fournit une résolution G-équivariante de $\mathcal{O}_{\mathcal{V}}$-modules qu'on peut écrire :

$$0 \to \mathcal{O}_{\mathcal{V}} \to \mathcal{O}_{\mathcal{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{c^{\vee}} \to \mathcal{O}_{\mathcal{V}} \to \mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}} \to 0,$$

d'où l'égalité qu'on voulait démontrer.

En considérant l'isomorphisme de R(G) sur $\mathrm{K}^{\mathrm{G}}(0)$ [analogue à celui de R(G) sur $\mathrm{K}^{\mathrm{G}}(\mathcal{V})$] induit par l'application qui à ρ associe $(\mathcal{O}_{\mathcal{V}}/\mathcal{M}_{\mathcal{V}}) \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^{\vee}}$, on a le diagramme suivant dont la commutativité résulte de la résolution précédente de $\mathcal{O}_{\mathscr{V}}/\mathcal{M}_{\mathscr{V}}$:

$$\begin{tikzcd}
\mathrm{R}(\mathrm{G}) \arrow[r, "2-c"] \arrow[d, "\cong"] & \mathrm{R}(\mathrm{G}) \arrow[d, "\cong"] \\
\mathrm{K}^{\mathrm{G}}(0) \arrow[r] & \mathrm{K}^{\mathrm{G}}(\mathscr{V})
\end{tikzcd}$$

Par suite l'image de $\mathrm{K}^{\mathrm{G}}(0)$ dans $\mathrm{K}^{\mathrm{G}}(\mathscr{V})=\mathrm{R}(\mathrm{G})$ est l'idéal engendré par $(2-c)$.

Pour démontrer (iii), on utilise le fait que la matrice $\mathrm{C}-2\,\mathrm{Id}$ [où $\mathrm{C}=((a_{ij}))$ est définie par $c\otimes\rho_i=\sum a_{ij}\,\rho_j$] restreinte au sous-groupe de $\mathrm{R}(\mathrm{G})$ engendré par les éléments de $\mathrm{Irr}(\mathrm{G})$ est définie négative, donc en particulier est non singulière. Par conséquent $(2-c)\,\mathrm{R}(\mathrm{G})$ est un $\mathbb{Z}$-module libre de rang au moins égal à $r=\mathrm{card}(\mathrm{Irr}(\mathrm{G}))$ et au plus égal à $r+1$, rang de $\mathrm{R}(\mathrm{G})$.

D'autre part, ainsi qu'on le voit en considérant les caractères correspondants, on a la relation $c\,\mathrm{reg}(\mathrm{G})=2\,\mathrm{reg}(\mathrm{G})$, où $\mathrm{reg}(\mathrm{G})=\sum_{i=0}^{r}(\deg\rho_i)\,\rho_i$ est la représentation régulière de G, car c est de degré 2. Comme $\mathrm{reg}(\mathrm{G})$ est un élément primitif de $\mathrm{R}(\mathrm{G})$, on a la suite exacte :

$$0\rightarrow\mathbb{Z}.\mathrm{reg}(\mathrm{G})\rightarrow\mathrm{R}(\mathrm{G})\xrightarrow{(2-c)}\mathrm{R}(\mathrm{G}),$$

et par suite $(2-c)\,\mathrm{R}(\mathrm{G})$ est de rang égal à r, et coïncide avec le $\mathbb{Z}$-module engendré par $(2-c)\,\rho$, $p\in\mathrm{Irr}(\mathrm{G})$. De la relation précédente on obtient :

$$2-c=\sum_{\rho\in\mathrm{Irr}(\mathrm{G})}(\deg\rho)(c-2)\,\rho,$$

car ρ_0 est la représentation triviale de degré 1; ce qui achève la démonstration de la proposition 1.4.

1.5. REMARQUE. — Le diagramme commutatif considéré dans la démonstration précédente se prolonge en le diagramme commutatif suivant :

$$\begin{tikzcd}
\mathrm{R}(\mathrm{G}) \arrow[r] \arrow[d, "\cong"] & \mathrm{R}(\mathrm{G}) \arrow[r] \arrow[d, "\cong"] & \mathrm{R}(\mathrm{G})/(2-c)\,\mathrm{R}(\mathrm{G}) \arrow[r] \arrow[d, "\cong"] & 0 \\
\mathrm{K}^{\mathrm{G}}(0) \arrow[r] & \mathrm{K}^{\mathrm{G}}(\mathscr{V}) \arrow[r] & \tilde{\mathrm{K}}^{\mathrm{G}}(\mathscr{V}-\{0\}) \arrow[r] & 0
\end{tikzcd}$$

où les lignes sont exactes et où $\tilde{\mathrm{K}}^{\mathrm{G}}(\mathscr{V}-\{0\})$ est le sous-groupe de Grothendieck construit à l'aide des faisceaux cohérents qui se prolongent à $\mathscr{V}$.

Ce diagramme permet de calculer $\tilde{\mathrm{K}}^{\mathrm{G}}(\mathscr{V}-\{0\})$: il est somme directe de son sous-groupe de torsion et de son sous-groupe cyclique infini engendré par son élément unité.

On obtient les résultat suivants :

Type de G :		$\tilde{K}^G(\mathscr{V}-\{0\})\cong$:
$\mathbf{A}_n (n \geqq 1)$		$\mathbb{Z}.1 \oplus \mathbb{Z}/(n+1)\mathbb{Z}$
$\mathbf{D}_n (n \geqq 4)$	si n pair	$\mathbb{Z}.1 \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$
	si n impair	$\mathbb{Z}.1 \oplus \mathbb{Z}/4\mathbb{Z}$
$\mathbf{E}_6$		$\mathbb{Z}.1 \oplus \mathbb{Z}/3\mathbb{Z}$
$\mathbf{E}_7$		$\mathbb{Z}.1 \oplus \mathbb{Z}/6\mathbb{Z}$
$\mathbf{E}_8$		$\mathbb{Z}.1$

2. Construction géométrique de la correspondance

2.1. On utilise les notations des paragraphes précédents.

Soit $\tilde{\mathscr{V}}=(\mathscr{V}\times_{\mathscr{S}}\tilde{\mathscr{S}})_{\text{réd}}$ le produit fibré réduit de $\mathscr{V}$ et $\tilde{\mathscr{S}}$ au-dessus de $\mathscr{S}$. On a le diagramme commutatif suivant :

$$\begin{tikzcd}
\tilde{\mathscr{V}} \arrow[r, "\mathrm{pr}_2"] \arrow[d, "\mathrm{pr}_1"'] & \tilde{\mathscr{S}} \arrow[d, "q"] \\
\mathscr{V} \arrow[r, "p"'] & \mathscr{S}
\end{tikzcd}$$

où pr_1 et pr_2 dénotent les projections canoniques.

2.2. THÉORÈME. — *Soit* π : $\mathrm{R(G)}=\mathrm{K^G}(\mathscr{V})\to \mathrm{K}(\tilde{\mathscr{S}})$ *l'application induite par la composition* $\mathrm{Inv}\circ \mathrm{pr}_{2*}\circ \mathrm{pr}_1^*$, *où* pr_1^* *et* pr_{2*} *sont les morphismes canoniques et où* Inv *est l'application qui associe à un* $\mathcal{O}_{\tilde{\mathscr{S}}}$*-module* G-*équivariant* M *le sous-module* $\mathrm{M^G}$ *des invariants pour l'action de* G. *Alors on a :*

(i) *Pour tout* $\rho\in \mathrm{Irr(G)}$ *il existe un unique* $d_\rho \in \mathrm{Irr(D)}$ *tel que* $\pi(\rho)=(\deg \rho, b_{d_\rho})$. *L'application* $\rho \to d_\rho$ *de* Irr(G) *dans* Irr(D) *est bijective. Pour* $\rho_i \neq \rho_j$ *on a* $(d_{\rho_i}.d_{\rho_j})=a_{ij}$ *(où* a_{ij} *est la multiplicité de* ρ_j *dans* $c\otimes\rho_i$*).*

(ii) $\pi(2-c)$ *est la classe* $[\mathscr{Z}]$ *du cycle fondamental, et pour tout* $\rho\in \mathrm{Irr(G)}$ *on a* $\pi((c-2)\rho)=[d_\rho]$.

(iii) *L'application* π *est un isomorphisme de* $\mathbb{Z}$*-modules.*

(iv) $\pi((2-c)\,\mathrm{R(G)})=\mathrm{Pic_D}(\tilde{\mathscr{S}})$.

(v) *Par passage au quotient* π *induit un isomorphisme d'anneaux :*

$$\mathrm{R(G)}/(2-c)\,\mathrm{R(G)} \xrightarrow{\sim} \mathrm{K}(\tilde{\mathscr{S}})/\mathrm{K_D}(\tilde{\mathscr{S}}).$$

2.3. COROLLAIRE. — *On a :*

$$[\mathscr{Z}]=\sum_{\rho\in \mathrm{Irr(G)}} (\deg \rho)\,[d_\rho].$$

Démonstration du corollaire 2.3. — En appliquant π aux deux membres de l'égalité :

$$2-c=\sum_{\rho\in \mathrm{Irr}(G)} (\deg\rho)(c-2)\,\rho$$

[prop. 1.2 (iii)], on obtient l'égalité cherchée comme conséquence du théorème 2.2 (ii).

La proposition suivante est un résultat préliminaire pour la démonstration du théorème 2.2; ses hypothèses sont un peu moins restrictives que celles satisfaites par la surface $\mathscr{S}$ de ce théorème.

2.4. PROPOSITION. — *Soit* $p:(\mathscr{V},0)\to(\mathscr{S},\bar{0})$ *un morphisme fini dominant où* $(\mathscr{V},0)$ *est un germe de surface normale, et où* $(\mathscr{S},\bar{0})$ *est un germe de singularité rationnelle de surface.*

Soit $q:\tilde{\mathscr{S}}\to\mathscr{S}$ *une désingularisation de* $\mathscr{S}$; *notons* $\mathscr{V}'=\mathscr{V}\times_{\mathscr{S}}\tilde{\mathscr{S}}$ *le produit fibré de* $\mathscr{V}$ *et* $\tilde{\mathscr{S}}$ *au-dessus de* $\mathscr{S}$ *et* $\tilde{\mathscr{V}}=\mathscr{V}'_{\mathrm{red}}$ *le réduit de* $\mathscr{V}'$. *Alors on a :*

(i) *L'homomorphisme canonique* (*de* $\mathcal{O}_{\mathscr{S}}$-*complexes*) $\mathcal{O}_{\mathscr{V}}\to q_*\mathcal{O}_{\tilde{\mathscr{V}}}$ *est un isomorphisme et on a de plus* $\mathrm{R}^1 q_*\mathcal{O}_{\tilde{\mathscr{V}}}=0$.

(ii) *Le* $\mathcal{O}_{\tilde{\mathscr{S}}}$-*module* $\mathcal{O}_{\tilde{\mathscr{V}}}$ *est localement libre.*

Montrons d'abord un lemme :

2.5. LEMME. — *Soit* A *un anneau commutatif noetherien et intègre, et* B *une* A-*algèbre finie irréductible, dominante, et génériquement réduite. Notons* $\mathscr{N}$ *l'idéal des éléments nilpotents de l'anneau* B *et* $\mathrm{Tors}_{\mathrm{A}}\,\mathrm{B}$ *la* A-*torsion de* B. *Alors on a :*

$$\mathscr{N}=\mathrm{Tors}_{\mathrm{A}}\,\mathrm{B}.$$

Démonstration du lemme 2.5. — En effet $\mathscr{N}$ est un A-module de type fini génériquement nul donc $\mathscr{N}\subset\mathrm{Tors}_{\mathrm{A}}\,\mathrm{B}$. L'algèbre $\mathrm{B}_{\mathrm{red}}$ est intègre donc sans A-torsion, car dominante, d'où $\mathrm{Tors}_{\mathrm{A}}\,\mathrm{B}\subset\mathscr{N}$.

Démonstration de la proposition 2.4. — Donc on a par la formule de projection pour les morphismes non nécessairement plats [Gr] :

$$\mathcal{O}_{\mathscr{V}}\mathop{\overset{\mathbb{L}}{\otimes}}_{\mathcal{O}_{\mathscr{S}}}\mathrm{R}q_*(\mathcal{O}_{\tilde{\mathscr{S}}})=\mathrm{R}q_*\left(\mathcal{O}_{\tilde{\mathscr{S}}}\mathop{\overset{\mathbb{L}}{\otimes}}_{\mathcal{O}_{\mathscr{S}}}\mathcal{O}_{\mathscr{V}}\right)$$

où le $\overset{\mathbb{L}}{\otimes}$ dénote le produit tensoriel dans la catégorie dérivée.

Étant donné que $\mathscr{S}$ est une singularité rationnelle, on a :

$$\mathrm{R}q_*(\mathcal{O}_{\tilde{\mathscr{S}}})=\mathcal{O}_{\mathscr{S}},$$

et par suite :

$$\mathcal{O}_{\mathscr{V}}=\mathrm{R}q_*\left(\mathcal{O}_{\tilde{\mathscr{S}}}\mathop{\overset{\mathbb{L}}{\otimes}}_{\mathcal{O}_{\mathscr{S}}}\mathcal{O}_{\mathscr{V}}\right).$$

Donc on a une suite spectrale, dont le terme $\mathrm{E}_2^{r,s}$ est $\mathrm{R}^r q_*\left(\mathscr{H}^s\left(\mathcal{O}_{\tilde{\mathscr{S}}}\mathop{\overset{\mathbb{L}}{\otimes}}_{\mathcal{O}_{\mathscr{S}}}\mathcal{O}_{\mathscr{V}}\right)\right)$, qui aboutit à $\mathcal{O}_{\mathscr{V}}$.

Comme $R^r q_* = 0$ pour $r \neq 0, 1$, on a la suite exacte de $\mathcal{O}_{\mathscr{S}}$-module :

$$0 \to R^1 q_*(\mathrm{Tor}_1^{\mathcal{O}_{\mathscr{S}}}(\mathcal{O}_{\tilde{\mathscr{S}}}, \mathcal{O}_{\mathscr{V}})) \to \mathcal{O}_{\mathscr{V}} \to q_*(\mathcal{O}_{\mathscr{V}'}) \to 0,$$

et :

$$R^1 q_* \mathcal{O}_{\mathscr{V}'} = 0.$$

Or le support de $R^1 q_*(\mathrm{Tor}_1^{\mathcal{O}_{\mathscr{S}}}(\mathcal{O}_{\tilde{\mathscr{S}}}, \mathcal{O}_{\mathscr{V}}))$ est de codimension positive, donc $R^1 q_*(\mathrm{Tor}_1^{\mathcal{O}_{\mathscr{S}}}(\mathcal{O}_{\tilde{\mathscr{S}}}, \mathcal{O}_{\mathscr{V}})) = 0$, car $\mathcal{O}_{\mathscr{V}}$ est intègre, et par suite $\mathcal{O}_{\mathscr{V}} \to q_*(\mathcal{O}_{\mathscr{V}'})$ est un isomorphisme.

Par ailleurs, $\mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'}$ est l'idéal des éléments nilpotents de $\mathcal{O}_{\mathscr{V}'}$ (lemme 2.5) car $\mathscr{V}'$ est irréductible et génériquement étale sur $\tilde{\mathscr{S}}$. Donc on a la suite exacte de $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules :

$$0 \to \mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'} \to \mathcal{O}_{\mathscr{V}'} \to \mathcal{O}_{\tilde{\mathscr{V}}} \to 0.$$

Or $q_* \mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'} = 0$ car $q_* \mathcal{O}_{\mathscr{V}'} \simeq \mathcal{O}_{\mathscr{V}}$ est intègre.

En vertu de ce qui précède on en déduit $R^1 q_* \mathcal{O}_{\tilde{\mathscr{V}}} = 0$, et la suite exacte $0 \to \mathcal{O}_{\mathscr{V}} \to q_* \mathcal{O}_{\tilde{\mathscr{V}}} \to R^1 q_* \mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'} \to 0$.

L'algèbre $q_* \mathcal{O}_{\tilde{\mathscr{V}}}$ est intègre et $R^1 q_* \mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'}$ est à support ponctuel. Comme $\mathcal{O}_{\mathscr{V}}$ est normal, on a $R^1 q_* \mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}} \mathcal{O}_{\mathscr{V}'} = 0$.

Finalement, le $\mathcal{O}_{\tilde{\mathscr{S}}}$-module $\mathcal{O}_{\tilde{\mathscr{V}}}$ est localement libre si et seulement si $\mathrm{Ext}^1_{\mathcal{O}_{\tilde{\mathscr{S}}}}(\mathcal{O}_{\tilde{\mathscr{V}}}, \omega_{\tilde{\mathscr{S}}}) = 0$, où $\omega_{\tilde{\mathscr{S}}}$ est le faisceau dualisant de $\tilde{\mathscr{S}}$, et la dualité relative pour q donne un isomorphisme :

$$\mathrm{Ext}^1_{\mathcal{O}_{\tilde{\mathscr{S}}}}(\mathcal{O}_{\tilde{\mathscr{V}}}, \omega_{\tilde{\mathscr{S}}}) = \mathrm{Ext}^1_{\mathcal{O}_{\mathscr{S}}}(Rq_* \mathcal{O}_{\tilde{\mathscr{V}}}, K_{\mathscr{S}}[-2]),$$

où $K_{\mathscr{S}}$ est le complexe dualisant de $\mathscr{S}$. Mais on a $Rq_* \mathcal{O}_{\tilde{V}} \simeq \mathcal{O}_V$, d'où un isomorphisme :

$$\mathrm{Ext}^1_{\mathcal{O}_{\tilde{\mathscr{S}}}}(\mathcal{O}_{\tilde{\mathscr{V}}}, \omega_{\tilde{\mathscr{S}}}) \simeq \mathrm{Ext}^1_{\mathcal{O}_{\mathscr{S}}}(\mathcal{O}_{\mathscr{V}}, K_{\mathscr{S}}[-2]).$$

La dualité relative pour p donne un isomorphisme :

$$\mathrm{Ext}^1_{\mathcal{O}_{\mathscr{S}}}(\mathcal{O}_{\mathscr{V}}, K_{\mathscr{S}}) \simeq \mathrm{Ext}^1_{\mathcal{O}_{\mathscr{V}}}(\mathcal{O}_{\mathscr{V}}, K_{\mathscr{V}}[-2]),$$

mais comme $\mathscr{V}$ est normale, $\mathscr{V}$ est de Cohen-Macaulay, donc $K_{\mathscr{V}}[-2]$ n'a qu'un seul module de cohomologie non nul en degré 0. Par suite $\mathrm{Ext}^1_{\mathcal{O}_{\mathscr{V}}}(\mathcal{O}_{\mathscr{V}}, K_{\mathscr{V}}[-2]) = 0$, donc $\mathcal{O}_{\tilde{\mathscr{V}}}$ est localement libre, ce qui achève la démonstration de la proposition 2.4.

2.6. Remarque. — La proposition 2.4 montre que $\tilde{\mathscr{S}}$ est un platificateur de $\mathscr{V}$ sur $\mathscr{S}$. Nous verrons plus loin que, sous les hypothèses du théorème 2.2 (i. e. $\mathscr{V}$ lisse, $\mathscr{S}$ point double rationnel et $\tilde{\mathscr{S}}$ désingularisation minimale de $\mathscr{S}$) $\tilde{\mathscr{S}}$ est le platificateur normal de $\mathscr{V}$ sur $\mathscr{S}$.

2.7. L'application $\pi : R(G) \to K(\tilde{\mathscr{S}})$ du théorème 2.2 est $\mathbb{Z}$-linéaire, donc il suffit, pour déterminer π, de calculer $\pi(\rho)$ pour chaque représentation irréductible ρ de G.

Soit $\mathscr{M}_\rho$ le $\mathcal{O}_{\mathscr{S}}$-module défini par :

$$\mathscr{M}_\rho = \mathrm{Hom}_{C[G]}(E_\rho, \mathcal{O}_{\mathscr{V}}).$$

On pose $\mathscr{F}_\rho = (\mathcal{O}_{\tilde{\mathscr{S}}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathscr{M}_\rho)/\mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}}$, où $\mathrm{Tors}_{\mathcal{O}_{\tilde{\mathscr{S}}}}$ dénote la $\mathcal{O}_{\tilde{\mathscr{S}}}$-torsion de $\mathcal{O}_{\tilde{\mathscr{S}}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathscr{M}_\rho$.

Avec les notations précédentes on a :

2.8. PROPOSITION. — *Les $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules $(\mathcal{O}_{\tilde{\mathscr{V}}} \underset{\mathcal{O}_{\mathscr{V}}}{\otimes} (\mathcal{O}_{\mathscr{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee}))^{\mathrm{G}}$ et $\mathscr{F}_\rho$ sont isomorphes.*

Démonstration. — Notons $\mathscr{N}$ l'idéal des éléments nilpotents d'un anneau et T_{A} la torsion d'un A-module.

On a :

$$(\mathcal{O}_{\tilde{\mathscr{V}}} \underset{\mathcal{O}_{\mathscr{V}}}{\otimes} (\mathcal{O}_{\mathscr{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee}))^{\mathrm{G}}$$

$$\simeq (\mathcal{O}_{\tilde{\mathscr{V}}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})^{\mathrm{G}} \text{ (par simplification du produit tensoriel)}$$

$$= (((\mathcal{O}_{\mathscr{V}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathcal{O}_{\tilde{\mathscr{S}}})/\mathscr{N}) \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})^{\mathrm{G}} \text{ (définition de } \mathcal{O}_{\tilde{\mathscr{V}}})$$

$$= (((\mathcal{O}_{\mathscr{V}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathcal{O}_{\tilde{\mathscr{S}}})/\mathrm{T}_{\mathcal{O}_{\tilde{\mathscr{S}}}}) \underset{\mathbb{C}}{\otimes} \mathrm{E}_\rho)^{\mathrm{G}} \text{ (lemme 2.5)}$$

$$\simeq ((\mathcal{O}_{\mathscr{V}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathcal{O}_{\tilde{\mathscr{S}}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})/\mathrm{T}_{\mathcal{O}_{\tilde{\mathscr{S}}}})^{\mathrm{G}}$$

(commutativité de la torsion avec la somme directe)

$$\simeq (\mathcal{O}_{\mathscr{V}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} \mathcal{O}_{\tilde{\mathscr{S}}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})^{\mathrm{G}}/\mathrm{T}^{\mathrm{G}}_{\mathcal{O}_{\tilde{\mathscr{S}}}}$$

(commutativité de l'action de G avec la torsion)

$$\simeq (\mathcal{O}_{\tilde{\mathscr{S}}} \underset{\mathcal{O}_{\mathscr{S}}}{\otimes} (\mathcal{O}_{\mathscr{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})^{\mathrm{G}})/\mathrm{T}^{\mathrm{G}}_{\mathcal{O}_{\tilde{\mathscr{S}}}}$$

(car $\mathcal{O}_{\tilde{\mathscr{S}}}$ et $\mathcal{O}_{\mathscr{S}}$ sont invariants par G).

$\simeq \mathscr{F}_\rho$ car on a un isomorphisme canonique :

$$\mathscr{M}_\rho = \mathrm{Hom}_{\mathbb{C}[\mathrm{G}]}(\mathrm{E}_\rho, \mathcal{O}_{\mathscr{V}}) \xrightarrow{\sim} (\mathcal{O}_{\mathscr{V}} \underset{\mathbb{C}}{\otimes} \mathrm{E}_{\rho^\vee})^{\mathrm{G}}.$$

En vue de la définition de l'application π du théorème 2.2, on a :

2.9. COROLLAIRE (prop. 2.8). — *L'application $\pi : \mathrm{R}(\mathrm{G}) \to \mathrm{K}(\tilde{\mathscr{S}})$ est induite aussi par celle qui associe à chaque représentation irréductible ρ de G le $\mathcal{O}_{\tilde{\mathscr{S}}}$-module $\mathscr{F}_\rho$.*

2.10. COROLLAIRE. — (i) *On a $q_* \mathscr{F}_\rho = \mathscr{M}_\rho$, $\mathrm{R}^1 q_* \mathscr{F}_\rho = 0$.*

(ii) *Le $\mathcal{O}_{\tilde{\mathscr{S}}}$-module $\mathscr{F}_\rho$ est localement libre de rang égal au degré de ρ.*

Démonstration. — Notons $\mathring{\mathrm{Irr}}(\mathrm{G}) := \mathrm{Irr}(\mathrm{G}) \cup \{\rho_0\}$. Si A est un anneau, A [G] dénote la A-algèbre du groupe G.

Il résulte de la proposition 2.8 et de la décomposition canonique des G-modules qu'on a un isomorphisme canonique de $\mathcal{O}_{\mathcal{Z}}$ [G]-modules :

$$\mathcal{O}_{\tilde{\mathcal{V}}} \simeq \bigoplus_{\rho \in \mathring{\mathrm{Irr}}(\mathrm{G})} \mathcal{F}_\rho \underset{\mathbb{C}}{\otimes} \mathrm{E}_\rho$$

et par suite :

$$q_* \mathcal{O}_{\tilde{\mathcal{V}}} \simeq \bigoplus_{\rho \in \mathring{\mathrm{Irr}}(\mathrm{G})} q_* \mathcal{F}_\rho \underset{\mathbb{C}}{\otimes} \mathrm{E}_\rho,$$

$$\mathrm{R}^1 q_* \mathcal{O}_{\tilde{\mathcal{V}}} \simeq \bigoplus_{\rho \in \mathring{\mathrm{Irr}}(\mathrm{G})} \mathrm{R}^1 q_* \mathcal{F}_\rho \underset{\mathbb{C}}{\otimes} \mathrm{E}_\rho.$$

De même, on a un isomorphisme canonique de $\mathcal{O}_{\mathcal{S}}$ [G]-modules :

$$\mathcal{O}_{\mathcal{V}} \simeq \bigoplus_{\rho \in \mathring{\mathrm{Irr}}(\mathrm{G})} \mathcal{M}_\rho \underset{\mathbb{C}}{\otimes} \mathrm{E}_\rho$$

d'où (i) d'après la proposition 2.4 et le fait que $\mathcal{F}_\rho$, facteur direct d'un module localement libre, est localement libre.

Localement, en dehors du diviseur D, $\mathcal{O}_{\tilde{\mathcal{V}}}$ est isomorphe à $\mathcal{O}_{\mathcal{Z}}$ [G], et (ii) résulte alors de la structure de la représentation régulière.

3. Rappel sur les groupes engendrés par des réflexions; les modules M_ρ

3.1. Pour chaque sous-groupe fini G de SL(2, $\mathbb{C}$), il existe un produit scalaire hilbertien de $\mathrm{V} = \mathbb{C}^2$ invariant par G et dans la suite on supposera donc que G est un sous-groupe fini de SU(2, $\mathbb{C}$); on sait par ailleurs que deux sous-groupes de SU(2, $\mathbb{C}$) sont conjugués si et seulement si ils le sont dans SL(2, $\mathbb{C}$).

Pour la démonstration du théorème 2.2 on utilisera le fait que chaque groupe polyédral binaire G est un sous-groupe d'indice 2 d'un groupe $\mathrm{G}' \subset \mathrm{U}(2, \mathbb{C})$ engendré par des réflexions complexes d'ordre 2 (*voir* [S – T], [Co]). Ceci est dû essentiellement au fait que déjà les groupes polyédraux purs sont des sous-groupes d'indice 2 de groupes engendrés par des réflexions de $\mathbb{R}^3$; ces derniers sont obtenus en considérant, en plus des rotations, les réflexions qui laissent fixe un polyèdre (*voir* [K], chap. 1, § 11 ou [D], § 12). Nous utiliserons le fait que G′/G opère sur les représentations de G en associant à chaque représentation ρ, sa contragrédiente $\check{\rho}$.

3.2. Notons $\mathrm{S}' = \mathrm{V}/\mathrm{G}'$ la surface obtenue comme quotient de V par G′, A_V l'anneau de polynômes à deux variables à coefficients dans $\mathbb{C}$, A_S (resp. $\mathrm{A}_{\mathrm{S}'}$) l'anneau de fonctions régulières globales sur S (resp. sur S′). Dans la suite on identifie l'anneau A_S (resp. $\mathrm{A}_{\mathrm{S}'}$) au sous-anneau de A_V des invariants de A_V par G (resp. G′).

On sait que A_V est un $A_{S'}$-module libre, et que $A_{S'}$ est une $\mathbb{C}$-algèbre (graduée) de polynômes ([Ch], [Bo], chap. V, § 5).

Notons Y, Z deux invariants homogènes de G′ qui engendrent $A_{S'}$ comme $\mathbb{C}$-algèbre; et considérons $X = J(Y, Z)$ le déterminant jacobien de Y et Z.

Alors X est un semi-invariant de G′ (*cf.* [Bo]), dont le carré est invariant par G′ car les réflexions de G′ sont d'ordre 2; et X, Y, Z sont trois invariants homogènes de G qui engendrent A_S comme $\mathbb{C}$-algèbre ([K], chap. 2).

Pour fixer les notations, soient Y et Z choisis de telle façon que $\deg(Z) \leqq \deg(Y)$; cette convention détermine X à un facteur constant près (sauf si G est de type $\mathbf{A}_1$), de même pour Y (sauf si G est de type $\mathbf{A}_n$ avec n impair ou $\mathbf{D}_n$ avec n pair), de même pour Z (sauf si G est de type $\mathbf{A}_1$ ou $\mathbf{D}_4$).

Dans le tableau suivant on donne les degrés de X, Y, Z dans chaque cas :

Type de G	deg(X)	deg(Y)	deg(Z)
$\mathbf{A}_n (n \geqq 1)$	$n+1$	$n+1$	2
$\mathbf{D}_n (n \geqq 4)$	$2(n-1)$	$2(n-2)$	4
$\mathbf{E}_6$	12	8	6
$\mathbf{E}_7$	18	12	8
$\mathbf{E}_8$	30	20	12

3.3. Notons ε la représentation de degré 1 de G′ définie par l'action de G′ sur $\mathbb{C}X$, où X est le semi-invariant considéré au paragraphe précédent.

Soit ρ (resp. ρ') une représentation de G (resp. G′). Par abus de notation on écrira $\varepsilon\rho'$ au lieu de $\varepsilon \otimes \rho$, $\operatorname{Ind}\rho$ au lieu de $\operatorname{Ind}_G^{G'}\rho$ (i. e. la représentation induite sur G′ par ρ [Se], § 7.1) et $\operatorname{Res}\rho'$ au lieu de $\operatorname{Res}_G \rho'$ (i. e. la représentation restreinte à G de ρ').

3.4. PROPOSITION. — *Soit* ρ *une représentation irréductible de* G. *Alors on a :*

(i) $\varepsilon \operatorname{Ind}\rho = \operatorname{Ind}\rho = \operatorname{Ind}\rho^{\vee}$.

(ii) $\rho \neq \rho^{\vee}$ *si et seulement si* $\operatorname{Ind}\rho$ *est irréductible.*

(iii) $\rho = \rho^{\vee}$ *si et seulement si* $\operatorname{Ind}\rho = \rho' \oplus \varepsilon\rho'$, *où* ρ' *est une représentation irréductible de* G′.

Soit ρ' *une représentation irréductible de* G′. *Alors on a :*

(i′) $\operatorname{Res}\rho' = \operatorname{Res}\varepsilon\rho' = (\operatorname{Res}\rho')^{\vee}$.

(ii′) $\rho' \neq \varepsilon\rho'$ *si et seulement si* $\operatorname{Res}\rho'$ *est irréductible.*

(iii′) $\rho' = \varepsilon\rho'$ *si et seulement si* $\operatorname{Res}\rho' = \rho \oplus \rho^{\vee}$, *où* ρ *est une représentation irréductible de* G.

Démonstration. — Quelque soit ρ' représentation de G′ on a :

$$(\operatorname{Ind}\rho) \otimes \rho' = \operatorname{Ind}(\rho \otimes \operatorname{Res}\rho'), \tag{1}$$

donc, si $\rho' = \varepsilon$ on a :

$$\varepsilon \operatorname{Ind}\rho = \operatorname{Ind}\rho, \tag{2}$$

car $\operatorname{Res}\varepsilon = \rho_0$, où ρ_0 est la représentation triviale de rang 1 de G; et si $\rho = \rho_0$ dans (1), alors :

$$\operatorname{Ind}\operatorname{Res}\rho' = \rho' \oplus \varepsilon\rho', \tag{3}$$

car $\operatorname{Ind}\rho_0=\rho'_0\oplus\varepsilon$, où ρ'_0 est la représentation triviale de rang 1 de G'. Par ailleurs, le groupe quotient G'/G agit sur les représentations de G en associant à chaque représentation ρ la contragrédiente $\rho^{\vee}$. Par suite on a :

$$\operatorname{Res}\operatorname{Ind}\rho=\rho\oplus\rho^{\vee}. \tag{4}$$

En appliquant Ind aux deux membres de (4), on a, par (3) :

$$\operatorname{Ind}\rho\oplus\varepsilon\operatorname{Ind}\rho=\operatorname{Ind}\rho\oplus\operatorname{Ind}\rho^{\vee},$$

par suite $\varepsilon\operatorname{Ind}\rho=\operatorname{Ind}\rho^{\vee}$, d'où (i), par (2).

Par le critère d'irréductibilité de Mackey ([Se], § 7.5), on a que $\operatorname{Ind}\rho$ est irréductible si et seulement si $\rho\neq\rho^{\vee}$, d'où (ii), et on a $\rho=\rho^{\vee}$ si et seulement si $\operatorname{Ind}\rho=\bigoplus_{i=1}^{m}\rho'_i$, avec $m>1$ et ρ'_i irréductible pour tout i. Or en appliquant Res aux deux membres on a , par (4), une somme de deux représentations irréductibles, donc $m\leqq 2$ et par suite $m=2$. Si $\rho=\rho^{\vee}$ on a donc

$$\operatorname{Res}(\rho'_1\oplus\rho'_2)=\rho\oplus\rho,$$

par suite

$$\operatorname{Res}\rho'_1=\operatorname{Res}\rho'_2=\rho,\quad \text{d'où}\quad \rho'_1\oplus\rho'_2=\operatorname{Ind}\rho=\operatorname{Ind}\operatorname{Res}\rho'_1=\rho'_1\oplus\varepsilon\rho'_1,$$

la dernière égalité par (3), d'où $\varepsilon\rho'_1=\rho'_2$, ce qui montre (iii).

Par ailleurs on a $\operatorname{Res}\varepsilon\rho'=(\operatorname{Res}\varepsilon)\otimes(\operatorname{Res}\rho')=\operatorname{Res}\rho'$, car $\operatorname{Res}\varepsilon=\rho_0$; et par (4) on a :

$$(\operatorname{Res}\rho')\oplus(\operatorname{Res}\rho')^{\vee}=\operatorname{Res}\operatorname{Ind}\operatorname{Res}\rho'=\operatorname{Res}(\rho'\oplus\varepsilon\rho')=(\operatorname{Res}\rho')\oplus(\operatorname{Res}\rho')$$

par suite $\operatorname{Res}\rho'=(\operatorname{Res}\rho')^{\vee}$, d'où (i').

Soit $\operatorname{Res}\rho'=\bigoplus_{i=1}^{m}\rho_i$ la décomposition en somme de représentation irréductibles de $\operatorname{Res}\rho'$; alors, par (3), on a $m\leqq 2$.

Si $\operatorname{Res}\rho'=\rho_1\oplus\rho_2$, alors $\rho'\oplus\varepsilon\rho'=\operatorname{Ind}\operatorname{Res}\rho'=(\operatorname{Ind}\rho_1)\oplus(\operatorname{Ind}\rho_2)$ et par suite $\operatorname{Ind}\rho_i$ est irréductible ($i=1$, 2), et on peut supposer $\operatorname{Ind}\rho_1=\rho'$, $\operatorname{Ind}\rho_2=\varepsilon\rho'$. En ce cas on a, par (4), $\rho_1\oplus\rho_1^{\vee}=\operatorname{Res}\operatorname{Ind}\rho_1=\operatorname{Res}\rho'=\rho_1\oplus\rho_2$, d'où $\rho_1^{\vee}=\rho_2$ et par (i) on a $\rho'=\varepsilon\rho'$.

Finalement, si $\operatorname{Res}\rho'=\rho$, alors par (3) on a $\operatorname{Ind}\rho=\rho'\oplus\varepsilon\rho'$. Or par la formule de réciprocité de Frobenius on a :

$$1=(\chi_\rho\mid\chi_{\operatorname{Res}\rho'})_G=(\chi_{\operatorname{Ind}\rho}\mid\chi_{\rho'})_{G'},$$

où χ dénote le caractère, et par conséquent $\rho'\neq\varepsilon\rho'$, ce qui achève la démonstration.

3.5. Soit ρ (resp. ρ') une représentation irréductible de G (resp. de G'). On considère le A_S-module gradué (resp. le $A_{S'}$-module gradué) M_ρ (resp. $M_{\rho'}$) défini par :

$$M_\rho=\operatorname{Hom}_{C[G]}(E_\rho, A_V)\quad [\text{resp. } M_{\rho'}=\operatorname{Hom}_{C[G']}(E_{\rho'}, A_V)].$$

On pose $U_\rho = M_\rho / \mathscr{M}_{S'} M_\rho$ et $U_{\rho'} = M_{\rho'} / \mathscr{M}_{S'} M_{\rho'}$, où $\mathscr{M}_{S'}$ est l'idéal maximal de $A_{S'}$ des éléments de degré strictement positif [i. e. $\mathscr{M}_{S'} = (Y, Z)$]; U_ρ (resp. $U_{\rho'}$) est un $\mathbb{C}$-espace vectoriel muni de la graduation canonique induite par celle de M_ρ (resp. $M_{\rho'}$). Il résulte de la proposition 3.4 le corollaire suivant :

3.6. Corollaire. — (i) *Si* $\rho \neq \check{\rho}$, *soit* $\rho' = \operatorname{Ind} \rho$. *On a des* $A_{S'}$*-isomorphismes* (*resp. des* $\mathbb{C}$*-isomorphismes*) *homogènes de degré* 0 :

$$M_\rho = M_{\rho'} = M_{\check{\rho}} \quad (\textit{resp. } U_\rho = U_{\rho'} = U_{\check{\rho}})$$

(ii) *Si* $\rho = \check{\rho}$, *soit* $\operatorname{Ind} \rho = \rho' \oplus \varepsilon \rho'$ *la décomposition en représentations irréductibles de* $\operatorname{Ind} \rho$. *On a un* $A_{S'}$*-isomorphisme* (*resp. un* $\mathbb{C}$*-isomorphisme*) *homogène de degré* 0 :

$$M_\rho = M_{\rho'} \oplus M_{\varepsilon\rho'} \quad (\textit{resp. } U_\rho = U_{\rho'} \oplus U_{\varepsilon\rho'}).$$

3.7. Notons c' la représentation canonique de G' définie par l'inclusion $G' \subset U(2, \mathbb{C})$. On peut définir un diagramme $\tilde{\Gamma}(G')$, de façon analogue à celle qui définit $\tilde{\Gamma}(G)$, en considérant maintenant le produit tensoriel par la représentation c'. Or, étant donné qu'on a en général $c' \neq \varepsilon c'$ (en fait on a égalité seulement si G est de type $\mathbf{A}_n$), on introduit lorsque $c' \neq \varepsilon c'$ des arêtes orientées : si ρ'_1 et ρ'_2 sont deux représentations irréductibles de G', on joint les deux sommets correspondants par une arête orientée de source ρ'_1 et de but ρ'_2 si ρ'_2 apparaît dans la décomposition de $c' \otimes \rho'_1$ en représentations irréductibles.

Dans la liste suivante on donne les diagrammes qu'on obtient. On utilise les notations de la proposition 3.4, et on fixe une numérotation des sommets qui sera maintenue dans la suite. Le sommet correspondant à la représentation triviale est indiqué par une croix.

4. Résolution G-équivariante de $\mathrm{A_V}$; l'opérateur Θ

4.1. On utilise les notations du paragraphe précédent. L'anneau $\mathrm{A_V}$ est muni d'une structure de $\mathrm{A_S}\,[\mathrm{G}]$-module gradué (resp. de $\mathrm{A_{S'}}\,[\mathrm{G'}]$-module gradué, resp. de $\mathrm{A_{S'}}\,[\mathrm{G}]$-module gradué).

Soit $\Theta : \mathrm{A_V} \to \mathrm{A_V}$ l'opérateur $\mathrm{A_{S'}}\,[\mathrm{G}]$-linéaire défini par $\Theta f = \mathrm{X} f$ pour $f \in \mathrm{A_V}$; il est homogène de degré égal au degré de X et il est aussi $\mathrm{A_S}\,[\mathrm{G}]$-linéaire.

Notons $\sigma : \mathrm{A_S} \to \mathrm{A_S}$ l'automorphisme d'ordre 2 de $\mathrm{A_{S'}}$-algèbre tel que $\sigma(\mathrm{X}) = -\mathrm{X}$. Pour tout $f \in \mathrm{A_V}$ et $h \in \mathrm{A_S}$ posons $h\,._{\sigma} f = \sigma(h) f$. On obtient ainsi une nouvelle structure de $\mathrm{A_S}$-module sur $\mathrm{A_V}$; cet $\mathrm{A_S}$-module est noté $\mathrm{A_V^{\sigma}}$.

Considérons le $\mathrm{A_{S'}}\,[\mathrm{G'}]$-module $\mathrm{A_V} \underset{\mathrm{A_{S'}}}{\otimes} \mathrm{A_S}$; il est aussi muni d'une structure de $\mathrm{A_S}\,[\mathrm{G}]$-module, et il est libre en tant que $\mathrm{A_S}$-module.

4.2. Lemme. — (i) *Le rang de* $\mathrm{A_V} \underset{\mathrm{A_{S'}}}{\otimes} \mathrm{A_S}$ *comme* $\mathrm{A_{S'}}$*-module est égal à* $2\,|\,\mathrm{G'}\,|$ *— où* $|\,\mathrm{G'}\,|$ *dénote l'ordre de* $\mathrm{G'}$ *—; et son rang comme* $\mathrm{A_S}$*-module est* $2\,|\,\mathrm{G}\,|$.

(ii) *On a deux suites exactes de* $\mathrm{A_S}\,[\mathrm{G}]$*-modules :*

$$0 \to \mathrm{A_V^{\sigma}} \xrightarrow{i^-} \mathrm{A_V} \underset{\mathrm{A_{S'}}}{\otimes} \mathrm{A_S} \xrightarrow{j^+} \mathrm{A_V} \to 0,$$

$$0 \to \mathrm{A_V} \xrightarrow{i^+} \mathrm{A_V} \underset{\mathrm{A_{S'}}}{\otimes} \mathrm{A_S} \xrightarrow{j^-} \mathrm{A_V^{\sigma}} \to 0$$

avec $i^+(f) = i^-(f) = f \otimes \mathrm{X} - \Theta f \otimes 1$ *:*

$$j^+(f \otimes h) = fh, \qquad j^-(f \otimes h) = h\,._{\sigma} f,$$
$$\forall f \in \mathrm{A_V}, \qquad \forall h \in \mathrm{A_S}.$$

Démonstration. — On a un isomorphisme de $\mathrm{A_{S'}}\,[\mathrm{G'}]$-modules $\mathrm{A_V} \simeq \mathrm{A_{S'}} \underset{\mathbb{C}}{\otimes} \mathrm{A_V} / \mathscr{M}_{\mathrm{S'}} \mathrm{A_V}$, où $\mathscr{M}_{\mathrm{S'}}$ dénote l'idéal maximal de $\mathrm{A_{S'}}$ engendré par Y et Z [Bo]; et d'autre part le $\mathbb{C}\,[\mathrm{G}]$-module gradué $\mathrm{A_V} / \mathscr{M}_{\mathrm{S'}} \mathrm{A_V}$ fournit une représentation régulière de $\mathrm{G'}$, d'où (i). La vérification de l'exactitude des suites de (ii) est immédiate.

4.3. Considérons par ailleurs l'opérateur $\mathrm{A_{S'}}\,[\mathrm{G}]$-linéaire homogène de $\mathrm{A_S}$ dans lui-même défini par la multiplication par X; on le notera aussi X. Il est aussi $\mathrm{A_S}\,[\mathrm{G}]$-linéaire.

4.4. PROPOSITION. — (i) *On a l'égalité* $\Theta^2 = X^2 \, \mathrm{Id}_{A_V}$ *où* $X^2 \, \mathrm{Id}_{A_V}$ *désigne la multiplication par* $X^2 \in A_{S'}$.

(ii) *Soient* T^+ (*resp.* T^-) : $A_V \otimes_{A_{S'}} A_S \to A_V \otimes_{A_{S'}} A_S$ *l'opérateur* $A_S[G]$-*linéaire homogène défini par :*

$$T^+ = \Theta \otimes \mathrm{Id}_{A_S} + \mathrm{Id}_{A_V} \otimes X \quad (\textit{resp.}\ T^- = \Theta \otimes \mathrm{Id}_{A_S} - \mathrm{Id}_{A_V} \otimes X).$$

Alors on a la suite exacte de $A_S[G]$-*modules :*

$$\ldots \xrightarrow{T^-} A_V \otimes_{A_{S'}} A_S \xrightarrow{T^+} A_V \otimes_{A_{S'}} A_S \xrightarrow{T^-} A_V \otimes_{A_{S'}} A_S \xrightarrow{j^+} A_V \to 0$$

où j^+ *est défini dans le lemme* 4.2. *On obtient ainsi une résolution du* $A_S[G]$-*module gradué* A_V *par des* $A_S[G]$-*modules gradués libres en tant que* A_S-*modules.*

Démonstration. — L'opérateur Θ est défini comme étant la multiplication par X, or $X^2 \in A_{S'}$, d'où (i). D'autre part on a $T^+ = i^+ \circ j^+$ et $T^- = i^- \circ j^-$. L'exactitude de la suite de (ii) est donc conséquence du lemme 4.1 (ii).

4.5. Pour chaque représentation irréductible ρ de G, on considère le module M_ρ comme $A_{S'}$-module (§ 3.5).

Soit $\theta_\rho = M_\rho \to M_\rho$ (resp. $j_\rho^+ : M_\rho \otimes_{A_{S'}} A_S \to M_\rho$) l'application $A_{S'}$-linéaire obtenue en appliquant $\mathrm{Hom}_{\mathbb{C}[G]}(E_\rho, -)$ à Θ (resp. à j^+). Posons :

$$T_\rho^+ = \theta_\rho \otimes \mathrm{Id}_{A_S} + \mathrm{Id}_{M_\rho} \otimes X$$
$$T_\rho^- = \theta_\rho \otimes \mathrm{Id}_{A_S} - \mathrm{Id}_{M_\rho} \otimes X.$$

On définit ainsi des opérateurs $A_{S'}$-linéaires (resp. A_S-linéaires) homogènes de $M_\rho \otimes_{A_{S'}} A_S$ dans lui-même. On a alors :

4.6. COROLLAIRE. — *On a la suite exacte de* A_S-*modules gradués :*

$$\ldots \xrightarrow{T_\rho^-} M_\rho \otimes_{A_{S'}} A_S \xrightarrow{T_\rho^+} M_\rho \otimes_{A_{S'}} A_S \xrightarrow{T_\rho^-} M_\rho \otimes_{A_{S'}} A_S \xrightarrow{j_\rho^+} M_\rho \to 0.$$

Cette suite exacte fournit une résolution de M_ρ *par des* A_S-*modules gradués libres* (*sur* A_S) *de rang* 2 deg ρ.

4.7. REMARQUE. — Pour $\rho \neq \rho_0$, on peut montrer que cette résolution est une résolution minimale.

5. La série de Poincaré; graduations et matrices

5.1. Soit $\rho \in \mathring{\mathrm{I}}\mathrm{rr}(G)$ [resp. $\rho' \in \mathring{\mathrm{I}}\mathrm{rr}(G')$] une représentation irréductible de G (resp. de G'). On considère le $\mathbb{C}$-espace vectoriel gradué $U_\rho = M_\rho / \mathscr{M}_{S'} M_\rho$ (resp. $U_{\rho'} = M_{\rho'} / \mathscr{M}_{S'} M_{\rho'}$) de dimension égal à 2 deg ρ (resp. égale à deg ρ'). Notons $U_{\rho,n}$ (resp. $U_{\rho',n}$) le sous-espace des éléments homogènes de degré n.

Posons :

$$P_\rho(T)=\sum_n(\dim_{\mathbb{C}} U_{\rho,n})\,T^n, \qquad P_{\rho'}(T)=\sum_n(\dim_{\mathbb{C}} U_{\rho',n})\,T^n;$$

ce sont des polynômes dans $\mathbb{Z}(T)$.

Soit $R(G)[T]$ (resp. $R(G')[T]$) l'anneau des polynômes à une variable à coefficients dans $R(G)$ [resp. dans $R(G')$].

Soit c (resp. c') la représentation canonique de G (resp. de G') et ρ_0 (resp. ρ'_0) la représentation triviale de degré 1 de G (resp. de G').

5.2. Proposition. — *Dans l'anneau* $R(G)[T]$ (*resp.* $R(G')[T]$) *on a l'égalité :*

$$\Big(\sum_{\rho\in \operatorname{Irr}(G)} \rho\, P_\rho(T)\Big)(\rho_0(1+T^2)-c\,T)=\rho_0(1-T^{\deg Y})(1-T^{\deg Z})$$

$$\Big[\textit{resp. } \Big(\sum_{\rho'\in \operatorname{Irr}(G')} \rho'\, P_{\rho'}(T)\Big)(\rho'_0-c'\,T+\varepsilon T^2)=\rho'_0(1-T^{\deg Y})(1-T^{\deg Z})\Big].$$

Démonstration. — Nous ferons la démonstration pour G, celle pour G' est analogue. Si M est un $\mathbb{C}[G]$-module, on note $[M]$ sa classe dans $R(G)$. Soit $A_V=\bigoplus_{n=0}^{\infty} A_{V,n}$ la décomposition en sous-espaces homogènes de A_V. On définit la série de Poincaré $\langle A_V\rangle$ dans l'anneau de séries formelles $R(G)[[T]]$ par :

$$\langle A_V\rangle=\sum_{n=0}^{\infty}[A_{V,n}]\,T^n.$$

Étant donnée que $[A_{V,n}]=[\operatorname{sym}^n(c)]$, alors on a :

$$\langle A_V\rangle=\sum_{n=0}^{\infty}[\operatorname{sym}^n(c)]\,T^n=1\Big/\Big(\sum_{n=0}^{\infty}(-1)^n[\Lambda^n(c)]\,T^n\Big).$$

Or $\Lambda^0(c)=\rho_0$, $\Lambda^1(c)=c$, $\Lambda^2(c)=\rho_0$ car $G\subset SU(2,\mathbb{C})$, et $\Lambda^n(c)=0$, $\forall n>2$. Par suite on a :

$$(1)\qquad \langle A_V\rangle=1/(\rho_0(1+T^2)-c\,T).$$

Considérons par ailleurs la décomposition de A_V en $\mathbb{C}[G]$-sous-modules isotypiques, $A_V=\bigoplus_{\rho\in\operatorname{Irr}(G)} A_{V,\rho}$, et soit $\langle A_{V,\rho}\rangle$ la série de Poincaré de $A_{V,\rho}$ dans $R(G)[[T]]$. Alors on a :

$$(2)\qquad \langle A_V\rangle=\sum_{\rho\in\operatorname{Irr}(G)}\langle A_{V,\rho}\rangle.$$

Posons $S_\rho(T)=\sum_{n=0}^{\infty}(\dim_{\mathbb{C}} M_{\rho,n})\,T^n\in\mathbb{C}[[T]]$. Par la définition de M_ρ on a un isomorphisme homogène $A_{V,\rho}=M_\rho \underset{\mathbb{C}}{\otimes} E_\rho$. Par suite on a :

$$\langle A_{V,\rho}\rangle=\rho\, S_\rho(T). \tag{3}$$

Finalement on a $M_\rho=U_\rho \underset{\mathbb{C}}{\otimes} A_{S'}$, d'où :

$$S_\rho(T)=P_\rho(T)/(1-T^{\deg Y})(1-T^{\deg Z}). \tag{4}$$

La proposition résulte des égalités (1) à (4).

5.3. La proposition précédente fournit une méthode effective pour le calcul de la graduation de U_ρ (resp. de $U_{\rho'}$), qui est donné par le polynôme $P_\rho(T)$ [resp. $P_{\rho'}(T)$]. Par ailleurs, on a (cor. 3.6) :

$$\begin{aligned} P_\rho(T)=P_{\check{\rho}}(T)=P_{\rho'}(T) \qquad &\text{si} \quad \rho\neq\check{\rho} \quad \text{et} \quad \rho'=\operatorname{Ind}\rho,\\ P_\rho(T)=P_{\rho'}(T)+P_{\varepsilon\rho'}(T) \qquad &\text{si} \quad \rho=\check{\rho} \quad \text{et} \quad \operatorname{Ind}\rho=\rho'\oplus\varepsilon\rho'; \end{aligned}$$

par conséquent, il sugfit de calculer $P_{\rho'}(T)$ pour toute représentation irréductible ρ' de G' pour déterminer $P_\rho(T)$ pour toute représentation irréductible ρ de G.

Dans la table suivante on donne la liste des résultats. Le calcul est réalisé en utilisant le fait que $P_{\rho'_0}(T)=1$ et $P_\varepsilon(T)=T^{\deg X}$. Si $P_{\rho'}(T)=\sum_{i=1}^{k} a_i T^{n_i}$, on donne la suite des degrés n_i, avec chaque entier n_i répété a_i fois, $i=1,\ldots,k$.

Les notations utilisées pour les représentations sont celles introduites au paragraphe 3.7.

5.3.1. *Type* $\mathbf{A}_n (n\geqq 1)$

	représentation	*degrés*

5.4. DÉFINITION DES MATRICES $[\theta_\rho]$; QUELQUES REMARQUES UTILES.

5.4.1. Soit M un $\mathrm{A}_{\mathrm{S}'}$-module gradué libre de type fini. Posons $\mathrm{U}=\mathrm{M}/\mathscr{M}_{\mathrm{S}'}\mathrm{M}$; U est gradué canoniquement par la graduation induite par celle de M. Notons M_n (resp. U_n) le sous-groupe de M (resp. de U) des éléments homogènes de degré n. Soit n un entier tel que $\mathrm{U}_n \neq 0$. On considère le sous-ensemble I_n de $\mathbb{Z}$ défini par :

$$\mathrm{I}_n=\{m \mid m=n+i, \text{ avec } \mathrm{U}_m \neq 0, \mathrm{A}_{\mathrm{S}',i} \neq 0\}.$$

On dira que M est bien gradué s'il satisfait la condition suivante : (BGr) : Si n et n' sont deux entiers tels que $n<n'$, $\mathrm{U}_n \neq 0$, $\mathrm{U}_{n'} \neq 0$, alors :

$$n' \in \mathrm{I}_n \Rightarrow \mathrm{I}_n \subset \mathrm{I}_{n'}$$
$$n' \notin \mathrm{I}_n \Rightarrow \mathrm{I}_n \cap \mathrm{I}_{n'} = \emptyset.$$

Soient $\mathrm{I}(1), \ldots, \mathrm{I}(h)$ les éléments maximaux (pour l'inclusion) de la famille $\{\mathrm{I}_n \mid n \in \mathbb{Z}\}$. Avec les notations précédentes on a :

5.4.2. Proposition. — *Supposons que* M *soit bien gradué.*

(i) *On a une décomposition canonique de* U *en somme directe :*

$$\mathrm{U} = \bigoplus_{k=1}^{h} \mathrm{U}^{(k)} \qquad \textit{avec} \quad \mathrm{U}^{(k)} = \bigoplus_{l \in \mathrm{I}_k} \mathrm{U}_l, \qquad 1 \leqq k \leqq h.$$

(ii) *Il existe une décomposition unique de* M *en somme directe de sous-modules gradués* $\mathrm{M} = \bigoplus_{k=1}^{h} \mathrm{M}^{(k)}$, *qui induit, modulo* $\mathscr{M}_{\mathrm{S}'}$, *la décomposition de* U *précédente.*

Démonstration. — Puisque M satisfait la condition (BGr), la famille $\{\mathrm{I}(k) \mid 1 \leqq k \leqq h\}$ est une partition de l'ensemble $\{n \mid \mathrm{U}_n \neq 0\}$, d'où (i).

Par ailleurs, si $\mathrm{M} = \bigoplus_{k} \mathrm{M}^{(k)}$ est une décomposition de M en somme directe telle que $\mathrm{M}^{(k)} / \mathscr{M}_{\mathrm{S}'} \mathrm{M}^{(k)} = \mathrm{U}^{(k)}$, alors $\mathrm{M}^{(k)}$ est le $\mathrm{A}_{\mathrm{S}'}$-sous-module de M engendré par les sous-groupes M_l avec $l \in \mathrm{I}(k)$; et il est clair que la famille des sous-modules $\mathrm{M}^{(k)}$ ainsi définie donne une décomposition de M en somme directe, d'où (ii).

5.4.3. Par inspection de la table 5.3, on vérifie que le module $\mathrm{M}_{\rho'}$ est bien gradué pour toute représentation irréductible ρ' de G′, à la seule exception de ρ'_3 du type $\mathbf{E}_7$ et ρ'_5 de $\mathbf{E}_8$. Or le type $\mathbf{E}_7$ est traité facilement à partir du type $\mathbf{E}_6$ (comme on verra dans le paragraphe 5.5) et le cas ρ_5 de $\mathbf{E}_8$ sera traité à part; donc, sauf indication contraire, on exclue dans la suite les cas exceptionnels. En conséquence de la proposition précédente, il y a une décomposition canonique de $\mathrm{M}_{\rho'}$ en somme directe de sous-modules $\mathrm{M}_{\rho'}^{(k)}$, avec $1 \leqq k \leqq h = h(\rho')$.

Supposons maintenant que ρ' apparaisse dans la décomposition en représentations irréductibles de $\operatorname{Ind} \rho$ où ρ est une représentation irréductible de G. Étant donné que l'opérateur θ_ρ est défini par la multiplication par le semi-invariant X de G′, on a l'inclusion : $\theta_\rho(\mathrm{M}_{\rho'}) \subset \mathrm{M}_{\varepsilon\rho'}$.

Notons $\theta_{\rho'} : \mathrm{M}_{\rho'} \to \mathrm{M}_{\varepsilon\rho'}$ la restriction de θ_ρ à $\mathrm{M}_{\rho'}$. On appelle *matrice* $[\theta_{\rho'}]$ associée à l'opérateur $\theta_{\rho'}$ le tableau indexé par $\{(k, \bar{k}), 1 \leqq k \leqq h(\rho'), 1 \leqq \bar{k} \leqq h(\varepsilon\rho')\}$ formé des blocks $[\theta_{\rho'}^{(k, \bar{k})}] : \mathrm{M}_{\rho'}^{(k)} \to \mathrm{M}_{\varepsilon\rho'}^{(\bar{k})}$.

5.4.4. *Remarques.* — (1) Notons $\mathrm{I}_{\rho'}$ l'ensemble de degrés $\{l \mid \mathrm{U}_{\rho', l} \neq 0\}$, et $\{\mathrm{I}_{\rho'}(k) \mid 1 \leqq k \leqq h\}$ la partition canonique de $\mathrm{I}_{\rho'}$ définie en 5.4.1. La table 5.3 montre que $\dim_{\mathbb{C}} \mathrm{U}_{\rho'}^{(k)}$ est égal à 1 ou 2 (et par suite $\operatorname{rang}_{\mathrm{A}_{\mathrm{S}'}} \mathrm{M}_{\rho'}^{(k)}$ est égal à 1 ou 2).

De fait on trouve trois cas possibles :

(*a*) $\mathrm{I}_{\rho'}(k) = \{l\}$ et $\dim_{\mathbb{C}} \mathrm{U}_{\rho', l} = 1$;

(*b*) $\mathrm{I}_{\rho'}(k) = \{l\}$ et $\dim_{\mathbb{C}} \mathrm{U}_{\rho', l} = 2$;

(*c*) $\mathrm{I}_{\rho'}(k) = \{l_1, l_2\}$ avec $l_1 < l_2$
et $\dim_{\mathbb{C}} \mathrm{U}_{\rho', l_1} = \dim_{\mathbb{C}} \mathrm{U}_{\rho', l_2} = 1$.

Dans le dernier cas on a une filtration de $\mathrm{M}_{\rho'}(k)$, $\mathrm{N}_{\rho'}^{(k)} \subset \mathrm{M}_{\rho'}^{(k)}$, où $\mathrm{N}_{\rho'}^{(k)}$ est le $\mathrm{A}_{\mathrm{S}'}$-sous-module de $\mathrm{M}_{\rho'}^{(k)}$ engendré par le sous-groupe M_{ρ', l_1}.

(2) En considérant les différents cas possibles [(*a*), (*b*) ou (*c*) de la remarque précédente] pour k et $\bar{k}$, on constate le fait suivant : Soit $B_{\rho'}^{(k)}$ une base, formée d'éléments homogènes, de $M_{\rho'}^{(k)}$. Alors il existe une base $B_{\varepsilon\rho'}^{(\bar{k})}$, formée d'éléments homogènes, de $M_{\varepsilon\rho'}^{(\bar{k})}$ telle que la matrice de $[\theta_{\rho'}^{(k,\bar{k})}]$ soit du type indiqué suivant le cas :

$\operatorname{rang}_{A_{S'}} M_{\rho'}^{(k)}$	$\operatorname{rang}_{A_{S'}} M_{\varepsilon\rho'}^{(\bar{k})}$	matrice de $[\theta_{\rho'}^{(k,\bar{k})}]$
1	1	$[f]$
1	2	$\begin{bmatrix} f \\ 0 \end{bmatrix}$
2	1	$[f \ \ 0]$
2	2	$\begin{bmatrix} f & h \\ 0 & g \end{bmatrix}$

où f (resp. g, resp. h) est un élément de $A_{S'}$ déterminé à un facteur scalaire près, ou nul.

(3) Posons $I_{S'} = \{ i \mid A_{S',i} \neq 0 \}$. Soit $l \in I_{\rho'}(k)$, et $\bar{l} \in I_{\rho'}(\bar{k})$. Considérons un élément m (resp. $\bar{m}$) homogène de degré l (resp. $\bar{l}$) appartenant à une base homogène $B_{\rho'}^{(k)}$ (resp. $B_{\varepsilon\rho'}^{(\bar{k})}$) de $M_{\rho'}^{(k)}$ (resp. de $M_{\varepsilon\rho'}^{(\bar{k})}$).

Alors, la composante de $\theta_{\rho'}(m)$ suivant $\bar{m}$ est un polynôme de la forme $\sum_{(a,b)} \alpha_{a,b} Y^a Z^b$, où a, b est un couple d'entiers positifs ou nuls parcourant l'ensemble :

$$\{ (a, b) \mid a \deg Y + b \deg Z = l - \bar{l} + \deg X \},$$

et où les $\alpha_{a,b}$ sont des constantes.

On en déduit donc, que si $(l - \bar{l} + \deg X) \notin I_{S'}$, alors ce polynôme est nul. De plus, sauf pour quelques représentations dans les cas $\mathbf{D}_n$ et $\mathbf{E}_7$, les polynômes en question sont des monômes.

(4) Soit ρ une représentation autoduale de G, et $\rho' \oplus \varepsilon\rho' = \operatorname{Ind} \rho$ la décomposition de $\operatorname{Ind} \rho$ en représentations irréductibles de G′ (prop. 3.4). Alors la décomposition $M_\rho = M_{\rho'} \oplus M_{\varepsilon\rho'}$ (cor. 3.6) induit une décomposition antidiagonale de θ_ρ, i. e. de la forme :

$$\begin{bmatrix} 0 & [\theta_{\varepsilon\rho'}] \\ [\theta_{\rho'}] & 0 \end{bmatrix}$$

(5) Soient ρ une représentation irréductible de G et $(x_i)_{i\in I}$ une famille finie d'éléments homogènes de A_V tels que pour tout i, $\mathbb{C}[G]x_i$ soit un sous-G-module simple de A_V de type ρ et tels que pour tout couple (i, j) il existe un $\mathbb{C}[G]$-isomorphisme $u_{i,j} : \mathbb{C}[G]x_i \to \mathbb{C}[G]x_j$ qui envoie x_i sur x_j. Alors il existe une famille $\langle x_i \rangle$, $i \in I$, d'éléments homogènes de $M_\rho = \operatorname{Hom}_{\mathbb{C}[G]}(E_\rho, A_V)$ tels que :
(*a*) $\langle x_i \rangle (E_\rho) = \mathbb{C}[G]x_i$.

(*b*) Le diagramme suivant soit commutatif :

$$\begin{tikzcd}
 & \mathbb{C}[G]\, x_i \arrow[dd, "u_{i.j}"] \\
E_\rho \arrow[ur, "\langle x_i\rangle"] \arrow[dr, "\langle x_j\rangle"'] & \\
 & \mathbb{C}[G]\, x_j
\end{tikzcd}$$

Une telle famille est déterminée au choix d'un scalaire non nul près. La même remarque est valable si on remplace G par G′.

(6) Étant donné que X^2 est un invariant du groupe G′, on a une relation de la forme :

$$(\star) \qquad X^2 = f(Y, Z)$$

où f est un polynôme à coefficients constants. On retrouve ainsi le fait que les points singuliers considérés sont des points doubles. Soient $\langle 1 \rangle$, $\langle X \rangle$ les éléments de la base de M_{ρ_0} (comme $A_{S'}$-module) déterminés par le polynôme constant 1 et par X respectivement. Avec cette base, la matrice de θ_{ρ_0} est la suivante :

$$\begin{bmatrix} 0 & f(Y, Z) \\ 1 & 0 \end{bmatrix}$$

(7) Comme conséquence de la proposition 4.4 (i), on a l'égalité :

$$(\theta_\rho)^2 = f(Y, Z) . \mathrm{Id}_{M_\rho},$$

où $f(Y, Z)$ provient de l'équation $(\star)$ de la remarque précédente. En particulier, si ρ est autoduale [*voir* remarque (4)], on a :

$$[\theta_{\rho'}]\,[\theta_{\varepsilon\rho'}] = f(Y, Z)\, \mathrm{Id}_{M_{\varepsilon\rho'}},$$
$$[\theta_{\varepsilon\rho'}]\,[\theta_{\rho'}] = f(Y, Z)\, \mathrm{Id}_{M_{\rho'}}$$

(8) Soient ρ_i, ρ_j et ρ_k trois représentations de G telles qu'on ait $\rho_i \otimes \rho_j = \rho_k$. Alors on a l'inclusion $M_{\rho_i} . M_{\rho_j} \subset M_{\rho_k}$, où $M_{\rho_i} . M_{\rho_j}$ dénote le produit symétrique de M_{ρ_i} avec M_{ρ_j}. Par suite, si m_i (resp. m_j) est un élément de M_{ρ_i} (resp. de M_{ρ_j}) on a les égalités :

$$\theta_{\rho_k}(m_i . m_j) = (\theta_{\rho_i}(m_i)) . m_j = m_i . (\theta_{\rho_j}(m_j)).$$

5.5. CALCUL DE LA RÉSOLUTION G-ÉQUIVARIANTE DE A_V (PROP. 4.4). — On utilisera la notation du paragraphe 3.7 pour les représentations. Les matrices données dans la liste suivante sont associées à des bases dont les éléments sont ordonnés par degrés croissants (*voir* table 5.3), pour chaque module $M_{\rho'}$. Les calculs sont effectués en utilisant les remarques 5.4.4. Pour chaque matrice on donne ses coordonnées en précisant la valeur du facteur constant seulement dans les cas où cette information est utile pour la suite, i. e. si la coordonnée en question n'est pas un monôme, ou si la représentation n'est pas autoduale; dans les autres cas on indique par $\star$ un coefficient constant non nul.

5.5.1. *Type* $\mathbf{A}_n$ $(n \geqq 1)$. — Dans ce cas il est plus facile de faire un calcul explicite.

Soit G le sous-groupe de SL(2, $\mathbb{C}$) engendré par $g=\begin{bmatrix} \xi & 0 \\ 0 & \xi^{-1} \end{bmatrix}$, où $\xi = e^{2\,i\pi/(n+1)}$.

Dans l'algèbre $A_V = \mathbb{C}[x, y]$ les polynômes $Y = x^{n+1} + y^{n+1}$ et $Z = xy$ engendrent $A_{S'}$, et le jacobien de Y et Z est égal (à un facteur scalaire près) à $(x^{n+1} - y^{n+1})$.

Pour simplifier les calculs, on considère les invariants de A_V pour l'action de G, définis par :

$$\overline{X} = x^{n+1}, \qquad \overline{Y} = y^{n+1}, \qquad \overline{Z} = Z = xy.$$

On notera que $\overline{X}$ et $\overline{Y}$ ne sont pas des invariants sous G′ et qu'on a $X = \overline{X} - \overline{Y}$ à un facteur près.

Notons $\rho_j (1 \leqq j \leqq n)$ la représentation irréductible (à isomorphisme près) dont le caractère en g vaut :

$$\chi_{\rho_j}(g) = \xi^j.$$

Posons $s_1(j) = \langle x^j \rangle$, $s_2(j) = \langle y^{n+1-j} \rangle$; ils forment une base de M_{ρ_j} [*cf.* remarque (5) de 5.4.4], $1 \leqq j \leqq n$.

Alors on a les relations :

$$\text{(R)} \qquad \begin{cases} \overline{Y}\, s_1(j) = \overline{Z}^j s_2(j) \\ \overline{Z}^{(n+1-j)} s_1(j) = \overline{X}\, s_2(j) \end{cases} \qquad (1 \leqq j \leqq n).$$

La relation $\overline{X}\,\overline{Y} = \overline{Z}^{(n+1)}$, qui n'est autre chose que l'équation, en termes de $\overline{X}$, $\overline{Y}$, $\overline{Z}$, de la singularité quotient, détermine avec les relations (R) la résolution de A_V (comme $A_S[G]$-module) de la proposition 4.4.

5.5.2. *Type* $\mathbf{D}_n (n \geqq 4)$. — Dans ce cas aussi on peut faire les calculs explicitement, en considérant le groupe dihédral binaire G engendré par :

$$g = \begin{bmatrix} \xi & 0 \\ 0 & \xi^{-1} \end{bmatrix} \quad \text{avec} \quad \xi = e^{2\,i\pi/2\,(n-2)} \quad \text{et par} \quad \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}.$$

Soient $Y = x^{2\,(n-2)} + (-1)^n y^{2\,(n-2)}$, $Z = x^2 y^2$ deux générateurs de $A_{S'}$, et notons X le polynôme $xy(x^{2\,(n-2)} + (-1)^{n-1} y^{2\,(n-2)})$, qui est égal au jacobien de Y et Z à un facteur scalaire près. On détermine une base de M_ρ, $\rho \in \operatorname{Irr}(G)$, en utilisant le cas cyclique (5.5.1) et le fait que G contient le sous-groupe distingué cyclique d'ordre $2(n-2)$ engendré par g. Avec les notations du paragraphe 3.7 pour les représentations de G on trouve :

(a) ρ_1 :

$$[\theta_{\rho_1}] = \begin{bmatrix} 0 & Y^2 + 4(-1)^{(n-1)} Z^{(n-2)} \\ Z & 0 \end{bmatrix}.$$

[Avec les bases de $M_{\varepsilon\rho'_1}$ et $M_{\rho'_1}$ respectivement : $\langle xy \rangle$, $\langle x^{2n-4} + (-1)^{n-1} y^{2n-4} \rangle$].

(*b*) ρ_j, $2 \leqq j \leqq n-2$:

j pair :

$$[\theta_{\rho_j}] = \begin{bmatrix} 0 & 0 & \star YZ & \star Z^{(n-1-j/2)} \\ 0 & 0 & \star Z^{j/2} & \star Y \\ \star Y & \star Z^{n-1-j/2} & 0 & 0 \\ \star Z^{j-2} & \star YZ & 0 & 0 \end{bmatrix}$$

(Avec les bases :
de $M_{\rho'_j}$: $\langle x^{j-1} \rangle$, $\langle xy^{2n-j-2} \rangle$;
de $M_{\varepsilon\rho'_j}$: $\langle x^j y \rangle$, $\langle y^{2n-j-3} \rangle$).

j impair :

$$[\theta_{\rho_j}] = \begin{bmatrix} 0 & 0 & \star YZ & \star Z^{(n-1-(j-1)/2)} \\ 0 & 0 & \star Z^{(j+1)/2} & \star YZ \\ \star Y & \star Z^{(n-2-(j-1)/2)} & 0 & 0 \\ \star Z^{(j-1)/2} & \star Y & 0 & 0 \end{bmatrix}$$

(Avec les bases :
de $M_{\rho'_j}$: $\langle x^{j-1} \rangle$, $\langle y^{2n-j-3} \rangle$;
de $M_{\varepsilon\rho'_j}$: $\langle x^j y \rangle$, $\langle xy^{2n-j-2} \rangle$).

(*c*) ρ_{n-1} :

n pair :

$$[\theta_{\rho_{n-1}}] = \begin{bmatrix} 0 & Y + 2Z^{(n-2)/2} \\ YZ - 2Z^{n/2} & 0 \end{bmatrix}.$$

[Avec les bases :
de $M_{\rho'_{n-1}}$: $\langle xy(x^{n-2} + (-1)^{n-1} y^{n-2}) \rangle$;
de $M_{\varepsilon\rho'_{n-1}}$: $\langle x^{n-2} + (-1)^j y^{n-2} \rangle$].

n impair :

$$[\theta_{\rho_{n-1}}] = \begin{bmatrix} YZ & -2Z^{(n-1)/2} \\ 2Z^{(n-1)/2} & Y \end{bmatrix}.$$

(même base).

(*d*) ρ_n :

n pair :

$$[\theta_{\rho_n}] = \begin{bmatrix} 0 & Y - 2Z^{(n-2)/2} \\ YZ + 2Z^{n/2} & 0 \end{bmatrix}.$$

[Avec les bases :
de $M_{\rho'_n}$: $\langle xy(x^{n+2} + (-1)^n y^{n-2}) \rangle$;
de $M_{\varepsilon\rho'_n}$: $\langle x^{n-2} + (-1)^{n-1} y^{n-2} \rangle$].

n impair :

$$[\theta_{\rho_n}]=\begin{bmatrix} YZ & 2Z^{(n-1)/2} \\ -2Z^{(n-1)/2} & Y \end{bmatrix}$$

(même base).

5.5.3. *Type* $\mathbf{E}_6$

Quitte à multiplier X, Y, Z par des facteurs scalaires, on peut normaliser l'équation de S de sorte qu'on ait :

$$X^2=Y^3+Z^4.$$

Les représentations ρ_1 et ρ_2 sont autoduales. On peut choisir des bases ordonnées par ordre ascendant des degrés telles que les matrices soient :

$$[\theta_{\rho'_1}]=\begin{bmatrix} \star Y & \star Z^3 \\ \star Z & \star Y^2 \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_1}]=\begin{bmatrix} \star Y^2 & \star Z^3 \\ \star Z & \star Y \end{bmatrix},$$

$$[\theta_{\rho'_2}]=\begin{bmatrix} \star Y & 0 & \star Z^2 \\ \star Z & \star Y & 0 \\ 0 & \star Z & \star Y \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_2}]=\begin{bmatrix} \star Y^2 & \star Z^3 & \star YZ^2 \\ \star YZ & \star Y^2 & \star Z^3 \\ \star Z^2 & \star YZ & \star Y^2 \end{bmatrix},$$

Pour les représentations ρ_3, $\rho_3^\vee$, ρ_4, $\rho_4^\vee$ on trouve :

$$[\theta_{\rho_3}]=\begin{bmatrix} \alpha Z^2 & 0 & Y^2 & 0 \\ 0 & \alpha Z^2 & \beta YZ & Y^2 \\ Y & 0 & -\alpha Z^2 & 0 \\ -\beta Z & Y & 0 & -\alpha Z^2 \end{bmatrix},$$

$$[\theta_{\rho_3^\vee}]=\begin{bmatrix} -\alpha Z^2 & 0 & Y^2 & 0 \\ 0 & -\alpha Z^2 & \beta YZ & Y^2 \\ Y & 0 & \alpha Z^2 & 0 \\ -\beta Z & Y & 0 & \alpha Z^2 \end{bmatrix},$$

$$[\theta_{\rho_4}]=\begin{bmatrix} \alpha Z^2 & Y^2 \\ Y & -\alpha Z^2 \end{bmatrix}, \qquad [\theta_{\rho_4^\vee}]=\begin{bmatrix} -\alpha Z^2 & Y^2 \\ Y & \alpha Z^2 \end{bmatrix},$$

où α et β sont deux constantes non nulles, $\alpha^2=1$ (on peut déterminer la valeur de β, mais c'est inutile pour la suite).

En fait le choix $\alpha=1$ (ou $\alpha=-1$) précise la représentation de G notée ρ_3 (et par suite détermine les trois autres).

On a utilisé en particulier le fait qu'on a les égalités :

$$\rho_1\otimes\rho_4=\rho_3 \qquad \text{et} \qquad \rho_4\otimes\rho_4^\vee=\rho_0$$

et la remarque (8) de 5.4.4.

A titre d'exemple, on montre comment on détermine les matrices dans le cas ρ_1 :

Notons $\{(1),(11)\}$ [resp. $\{(5),(7)\}$] une base de $M_{\rho_1'}$ (resp. de $M_{\varepsilon\rho_1'}$) dont les éléments sont de degré égal au chiffre indiqué (*voir* table 5.3.3).

Par des considérations de degrés [remarque (3) de 5.4.4], en considérant les degrés de X, Y, Z (*voir* § 3.2), les matrices associées aux opérateurs $\theta_{\rho_1'} : M_{\rho_1'} \to M_{\varepsilon\rho_1'}$ et $\theta_{\varepsilon\rho_1'} \to M_{\rho_1'}$ avec ces bases, sont de la forme :

$$[\theta_{\rho_1'}]=\begin{array}{c} \begin{array}{cc} \theta(1) & \theta(11) \end{array} \\ \begin{bmatrix} aY & bZ^3 \\ cZ & dY^2 \end{bmatrix} \end{array} \begin{array}{l} \\ (5) \\ (7), \end{array} \qquad [\theta_{\varepsilon\rho_1'}]=\begin{array}{c} \begin{array}{cc} \theta(5) & \theta(7) \end{array} \\ \begin{bmatrix} eY^2 & fZ^3 \\ gZ & hY \end{bmatrix} \end{array} \begin{array}{l} \\ (1) \\ (11) \end{array}$$

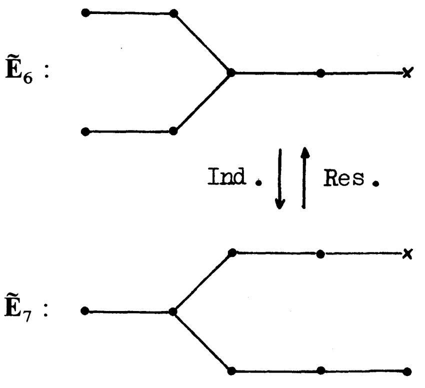
où $a, b, \ldots, h$ sont des coefficients constants. Or ces matrices doivent satisfaire les égalités :

$$[\theta_{\rho_1'}][\theta_{\varepsilon\rho_1'}]=(Y^3+Z^4)\,\mathrm{Id}_{M_{\varepsilon\rho_1'}} \quad \text{et} \quad [\theta_{\varepsilon\rho_1'}][\theta_{\rho_1'}]=(Y^3+Z^4)\,\mathrm{Id}_{M_{\rho_1'}}$$

[remarque (7) de 5.4.4], d'où en particulier : $ae=bg=ef=dh=1$, et par suite tous les coefficients sont non nuls. En fait on peut être plus précis, car en faisant des homothéties sur les éléments des bases, on peut supposer $a=b=c=1$, d'où $e=f=g=1$. D'autre part on a aussi $1+h=af+bh=0$, d'où $h=-1$ et par suite $d=-1$:

$$\begin{bmatrix} Y & Z^3 \\ Z & -Y^2 \end{bmatrix}, \quad \begin{bmatrix} Y^2 & Z^3 \\ Z & -Y \end{bmatrix}.$$

5.5.4. *Type* $\mathbf{E}_7$. — Un groupe G de type $\mathbf{E}_7$ contient un sous-groupe distingué d'indice 2 de type $\mathbf{E}_6$ (ceci est dû essentiellement au fait que la réunion des sommets d'un tétraèdre et du tétraèdre dual est l'ensemble de sommets d'un cube). La relation (par induction ou restriction) entre les représentations irréductibles de l'un et de l'autre est exprimée schématiquement par la correspondance de diagrammes suivante :



de sorte que la restriction (resp. l'induction) d'une représentation irréductible du groupe de type $\tilde{\mathbf{E}}_7$ (resp. de type $\tilde{\mathbf{E}}_6$) correspondante à un sommet du diagramme $\tilde{\mathbf{E}}_7$ (resp. de $\tilde{\mathbf{E}}_6$) est la somme de représentations correspondantes aux sommets du diagramme $\tilde{\mathbf{E}}_6$ (resp. $\tilde{\mathbf{E}}_7$) qui se trouvent sur la même verticale.

D'autre part, si on note Y_6, Z_6 (resp. Y_7, Z_7) des générateurs de $A_{S'}$ et X_6 (resp. X_7) leur jacobien dans le cas $\mathbf{E}_6$ (resp. $\mathbf{E}_7$), on a les égalités (à un facteur constant non nul près) suivantes :

$$X_7 = X_6 Z_6, \qquad Y_7 = Z_6^2, \qquad Z_7 = Y_6.$$

Ces deux remarques permettent de déduire la résolution équivariante de A_V pour le type $\mathbf{E}_7$ à partir de celle de type $\mathbf{E}_6$.

Quitte à multiplier $X = X_7$, $Y = Y_7$ et $Z = Z_7$ par des constantes, on a la relation :

$$X^2 = Y(Y^2 + Z^3).$$

Les matrices trouvées sont les suivantes :

$$[\theta_{\rho'_1}] = \begin{bmatrix} \star Y & \star YZ^2 \\ \star Z & \star Y^2 \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_1}] = \begin{bmatrix} \star Y^2 & \star YZ^2 \\ \star Z & \star Y \end{bmatrix},$$

$$[\theta_{\rho'_2}] = \begin{bmatrix} \star Y & 0 & \star YZ \\ \star Z & \star Y & 0 \\ 0 & \star Z & \star Y \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_2}] = \begin{bmatrix} \star Y^2 & \star YZ^2 & \star Y^2 Z \\ \star YZ & \star Y^2 & \star YZ^2 \\ \star Z^2 & \star YZ & \star Y^2 \end{bmatrix},$$

$$[\theta_{\rho'_3}] = \begin{bmatrix} 0 & \star YZ & \star Y^2 & \star YZ^2 \\ \star Y & 0 & \star YZ & \star Y^2 \\ \star Y & \star Z^2 & 0 & 0 \\ \star Z & \star Y & 0 & 0 \end{bmatrix},$$

$$[\theta_{\varepsilon\rho'_3}] = \begin{bmatrix} 0 & 0 & \star Y^2 & \star YZ^2 \\ 0 & 0 & \star YZ & \star Y^2 \\ \star Y & \star Z^2 & 0 & \star YZ \\ \star Z & \star Y & \star Y & 0 \end{bmatrix}$$

$$[\theta_{\rho'_4}] = \begin{bmatrix} 0 & \star YZ & \star Y^2 \\ \star Y & 0 & \star YZ \\ \star Z & \star Y & 0 \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_4}] = \begin{bmatrix} \star YZ & \star Y^2 & \star YZ^2 \\ \star Z^2 & \star YZ & \star Y^2 \\ \star Y & \star Z^2 & \star YZ \end{bmatrix},$$

$$[\theta_{\rho'_5}] = \begin{bmatrix} \star Z^2 & \star Y \\ \star Y & \star YZ \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_5}] = \begin{bmatrix} \star YZ & \star Y^2 \\ \star Y & \star Z^2 \end{bmatrix},$$

$$[\theta_{\rho'_6}] = [Y], \qquad [\theta_{\varepsilon\rho'_6}] = [Y^2 + Z^3],$$

$$[\theta_{\rho'_7}] = \begin{bmatrix} \star Y & \star Z^2 \\ \star Z & \star Y \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_7}] = \begin{bmatrix} \star Y^2 & \star YZ^2 \\ \star YZ & \star Y^2 \end{bmatrix},$$

5.5.5. *Type* $\mathbf{E}_8$. — Quitte à multiplier X, Y, Z par des facteurs constants, on a la relation :

$$X^2 = Y^3 + Z^5$$

Les matrices trouvées sont les suivantes :

$$[\theta_{\rho'_1}] = \begin{bmatrix} \star Y & \star Z^4 \\ \star Z & \star Y^2 \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_1}] = \begin{bmatrix} \star Y^2 & \star Z^4 \\ \star Z & \star Y \end{bmatrix},$$

$$[\theta_{\rho'_2}] = \begin{bmatrix} \star Y & 0 & \star Z^3 \\ \star Z & \star Y & 0 \\ 0 & \star Z & \star Y \end{bmatrix}, \qquad [\theta_{\varepsilon\rho'_2}] = \begin{bmatrix} \star Y^2 & \star Z^4 & \star YZ^3 \\ \star YZ & \star Y^2 & \star Z^4 \\ \star Z^2 & \star YZ & \star Y^2 \end{bmatrix},$$

$$[\theta_{\rho'_3}] = \begin{bmatrix} \star Z^2 & 0 & \star Y^2 & \star Z^4 \\ \star Y & 0 & \star Z^3 & \star YZ^2 \\ 0 & \star Z^2 & \star YZ & \star Y^2 \\ \star Z & \star Y & 0 & \star Z^3 \end{bmatrix},$$

$$[\theta_{\varepsilon\rho'_3}] = \begin{bmatrix} \star Z^3 & \star Y^2 & \star YZ^2 & \star Z^4 \\ 0 & \star YZ & \star Z^3 & \star Y^2 \\ \star Y & \star Z^2 & 0 & 0 \\ \star Z & 0 & \star Y & \star Z^2 \end{bmatrix},$$

$$[\theta_{\rho'_4}] = \begin{bmatrix} \star Z^2 & 0 & 0 & 0 & \star Y^2 \\ \star Y & 0 & 0 & 0 & \star Z^3 \\ 0 & \star Y & \star Z^2 & 0 & 0 \\ \star Z & 0 & \star Y & \star Z^2 & 0 \\ 0 & \star Z & 0 & \star Y & \star Z^2 \end{bmatrix},$$

$$[\theta_{\varepsilon\rho'_4}] = \begin{bmatrix} \star Z^3 & \star Y^2 & 0 & 0 & 0 \\ 0 & \star Z^3 & \star Y^2 & \star YZ^2 & \star Z^4 \\ 0 & \star YZ & \star Z^3 & \star Y^2 & \star YZ^2 \\ \star Z^2 & 0 & \star YZ & \star Z^3 & \star Y^2 \\ \star Y & \star Z^2 & 0 & 0 & 0 \end{bmatrix},$$

$$[\theta_{\rho'_5}]=\begin{bmatrix} 0 & 0 & \bigstar Z^3 & \bigstar Y^2 & \bigstar YZ^2 & \bigstar Z^4 \\ \bigstar Z^2 & 0 & 0 & \bigstar Z^3 & \bigstar Y^2 & \bigstar YZ^2 \\ 0 & \bigstar Z^2 & 0 & \bigstar YZ & \bigstar Z^3 & \bigstar Y^2 \\ \bigstar Y & \bigstar Z^2 & 0 & 0 & 0 & 0 \\ 0 & \bigstar Y & \bigstar Z^2 & 0 & 0 & 0 \\ \bigstar Z & 0 & \bigstar Y & 0 & 0 & 0 \end{bmatrix},$$

$$[\theta_{\varepsilon\rho'_5}]=\begin{bmatrix} 0 & 0 & 0 & \bigstar Y^2 & \bigstar YZ^2 & \bigstar Z^4 \\ 0 & 0 & 0 & \bigstar Z^3 & \bigstar Y^2 & \bigstar YZ^2 \\ 0 & 0 & 0 & \bigstar YZ & \bigstar Z^3 & \bigstar Y^2 \\ \bigstar Y & \bigstar Z^2 & 0 & 0 & 0 & \bigstar Z^3 \\ 0 & \bigstar Y & \bigstar Z^2 & \bigstar Z^2 & 0 & 0 \\ \bigstar Z & 0 & \bigstar Y & 0 & \bigstar Z^2 & 0 \end{bmatrix},$$

$$[\theta_{\rho'_6}]=\begin{bmatrix} 0 & \bigstar Z^3 & \bigstar Y^2 & \bigstar YZ \\ \bigstar Z^2 & 0 & 0 & \bigstar Y^2 \\ \bigstar Y & 0 & 0 & \bigstar Z^3 \\ \bigstar Z & \bigstar Y & \bigstar Z & 0 \end{bmatrix},$$

$$[\theta_{\varepsilon\rho'_6}]=\begin{bmatrix} O & \bigstar Z^3 & \bigstar Y^2 & 0 \\ \bigstar Z^2 & 0 & \bigstar YZ & \bigstar Y^2 \\ \bigstar Y & \bigstar Z^2 & 0 & \bigstar Z^3 \\ 0 & \bigstar Y & \bigstar Z^2 & 0 \end{bmatrix},$$

$$[\theta_{\rho'_7}]=\begin{bmatrix} \bigstar Z^2 & \bigstar Y^2 \\ \bigstar Y & \bigstar Z^3 \end{bmatrix},\qquad [\theta_{\varepsilon\rho'_7}]=\begin{bmatrix} \bigstar Z^3 & \bigstar Y^2 \\ \bigstar Y & \bigstar Z^2 \end{bmatrix},$$

$$[\theta_{\rho'_8}]=\begin{bmatrix} \bigstar Y & \bigstar Z^2 & 0 \\ 0 & \bigstar Y & \bigstar Z^2 \\ \bigstar Z & \bigstar Z^2 & \bigstar Y^2 \end{bmatrix},\qquad [\theta_{\varepsilon\rho'_8}]=\begin{bmatrix} \bigstar Y^2 & \bigstar YZ^2 & \bigstar Z^4 \\ \bigstar Z^3 & \bigstar Y^2 & \bigstar YZ^2 \\ \bigstar YZ & \bigstar Z^3 & \bigstar Y^2 \end{bmatrix},$$

Les matrices correspondantes aux indices 1, 2, 7 et 8 sont déterminées par des considérations de degrés [remarque (3), § 5.4.4] et par la condition de la remarque (7), § 5.4.4. La même méthode détermine les autres matrices, à quelques coefficients près; et ces derniers sont déterminés par la connaissance des matrices d'indices 1, 2, 7, 8 et la remarque (8) appliquée (par exemple) aux égalités :

$$\rho_1\otimes\rho_8=\rho_5,\qquad \rho_1\otimes\rho_7=\rho_6,\qquad \rho_1\otimes\rho_2=\rho_1\oplus\rho_3,\qquad \rho_1\otimes\rho_3=\rho_2\oplus\rho_4.$$

6. Désingularisations minimales; démonstration du théorème 2.2

6.1. On dispose de désingularisations minimales explicites $q : \tilde{S} \rightarrow S$ qui sont construites par une procédure de « soudure » à partir de plusieurs copies de $\mathbb{C}^2$ ([G], *voir* aussi [H], [L]). Le morphisme q qui contracte le diviseur exceptionnel $D = \bigcup_k d_k$ de $\tilde{S}$ est déterminé essentiellement par la donnée des cycles (à support dans D) de la forme $\sum_n n_k d_k$, qui seront représentés par des diagrammes analogues au graphe dual associé à D, où on remplace le sommet correspondant à une composante irréductible d_k par la multiplicité n_k.

6.1.1. *Type* $\mathbf{A}_n$ $(n \geqq 1)$. — Pour chaque entier k, $0 \leqq k \leqq n$, soit $\mathcal{U}_k$ une copie de $\mathbb{C}^2$ de coordonnées (u_k, v_k). Soit $\tilde{S}$ la surface (lisse) obtenue en identifiant les ouverts $\mathcal{U}_{k-1} - \{u_{k-1} = 0\}$ et $\mathcal{U}_k - \{v_k = 0\}$, $1 \leqq k \leqq n$, par les recollements :

$$u_{k-1} = 1/v_k, \qquad v_{k-1} = u_k v_k^2.$$

Soit d_k la courbe rationnelle lisse définie par $v_{k-1} = 0$ dans $\mathcal{U}_{k-1}$ et par $u_k = 0$ dans $\mathcal{U}_k$, $1 \leqq k \leqq n$. Alors chaque d_k a une auto-intersection -2 et le graphe dual associé à $D = \bigcup_k d_k$ est $\mathbf{A}_n$. Notons $C(\overline{X})$, $C(\overline{Y})$, $C(\overline{Z})$ les cycles à support dans D définis par les diagrammes :

$$C(\overline{X}) : n(n-1)\ldots 1 \left[\text{i.e. } C(\overline{X}) = \sum_{k=1}^{n} (n+1-k)\, d_k\right]$$

$$C(\overline{Y}) : 1\ \ 2\ldots n \left[\text{i.e. } C(\overline{Y}) = \sum_{k=1}^{n} k\, d_k\right]$$

$$C(\overline{Z}) : 1\ \ 1\ldots 1 \left[\text{i.e. } C(\overline{Z}) = \sum_{k=1}^{n} d_k\right].$$

A l'aide de ces cycles on définit une application $q : \tilde{S} \rightarrow \mathbb{C}^3$ par :

$$q|_{\mathcal{U}_k}(u_k, v_k) = (u_k^{(n+1-k)}\, v_k^{(n-k)},\ u_k^k\, v_k{}^{+1},\ u_k v_k), \qquad 0 \leqq k \leqq n.$$

Notons $(\overline{X}, \overline{Y}, \overline{Z})$ les coordonnées de $\mathbb{C}^3$. On vérifie que l'application q est une désingularisation minimale de la surface S (plongée dans $\mathbb{C}^3$) d'équation : $\overline{X}\,\overline{Y} = \overline{Z}^{(n+1)}$.

6.1.2. *Type* $\mathbf{D}_n$ $(n \geqq 4)$. — Pour chaque entier k, $0 \leqq k \leqq n$, soit $\mathcal{U}_k$ une copie de $\mathbb{C}^2$ de coordonnées (u_k, v_k). Soit $\tilde{S}$ la surface (lisse) obtenue en identifiant :

les ouverts $\mathcal{U}_{k-1} - \{u_{k-1} = 0\}$ et $\mathcal{U}_k - \{v_k = 0\}$, $1 \leqq k \leqq n-2$ par les recollements :

$$u_{k-1} = 1/v_k \quad \text{et} \quad v_{k-1} = u_k v_k^2,$$

les ouverts $\mathcal{U}_{n-2} - \{u_{n-2} = 0\}$ et $\mathcal{U}_{n-1} - \{v_{n-1} = 0\}$ par les recollements :

$$u_{n-2} = 1/v_{n-1} \quad \text{et} \quad \begin{cases} v_{n-2} + i = u_{n-1} v_{n-1}^2 & \text{si } n \text{ pair,} \\ v_{n-2} + 1 = u_{n-1} v_{n-1}^2 & \text{si } n \text{ impair,} \end{cases}$$

les ouverts $\mathscr{U}_{n-2}-\{u_{n-2}=0\}$ et $\mathscr{U}_{n}-\{v_{n}=0\}$ par les recollements :

$$u_{n-2}=1/v_n \qquad \text{et} \qquad \begin{cases} v_{n-2}-i=u_n v_n^2 & \text{si } n \text{ pair,} \\ v_{n-2}-1=u_n v_n^2 & \text{si } n \text{ impair,} \end{cases}$$

Soit d_k la courbe rationnelle lisse définie par $v_{k-1}=u_k=0$, avec $1 \leqq k \leqq n-2$;

d_{n-1} définie par :

$$u_{n-1}=0 \qquad \text{et} \qquad \begin{cases} v_{n-2}+i=0 & \text{si } n \text{ pair,} \\ v_{n-2}+1=0 & \text{si } n \text{ impair,} \end{cases}$$

d_n définie par :

$$u_n=0 \qquad \text{et} \qquad \begin{cases} v_{n-2}-i=0 & \text{si } n \text{ pair,} \\ v_{n-2}-1=0 & \text{si } n \text{ impair,} \end{cases}$$

Alors chaque d_k a une auto-intersection -2 et le graphe dual associé à $\mathrm{D}=\bigcup_k d_k$ est $\mathbf{D}_n$.

Avec les cycles C(X), C(Y), C(Z) définis par :

$$\begin{array}{rll} & n \text{ pair} & n \text{ impair} \\ \mathrm{C(X)}: & 2\ 3 \ldots (n-1)\begin{smallmatrix} n/2 \\ n/2 \end{smallmatrix} & 2\ 3 \ldots (n-1)\begin{smallmatrix} (n-1)/2 \\ (n-1)/2 \end{smallmatrix} \\ \mathrm{C(Y)}: & 1\ 2 \ldots (n-2)\begin{smallmatrix} n/2-1 \\ n/2-1 \end{smallmatrix} & 1\ 2 \ldots (n-2)\begin{smallmatrix} (n-1)/2 \\ (n-1)/2 \end{smallmatrix} \\ \mathrm{C(Z)}: & 2\ 2 \ldots 2_1^1 & 2\ 2 \ldots 2_1^1 \end{array}$$

On définit une application $q : \tilde{\mathrm{S}} \rightarrow \mathbb{C}^3$, dont les restrictions aux ouverts précédents sont données par :

si $0 \leqq k \leqq n-3$:

$$\mathrm{X}=u_k^{k+1} v_k^{k+2}(1+(-1)^n u_k^{2(n-k-2)} v_k^{2(n-k-3)})^{a_k},$$

$$\text{avec } a_k=\begin{cases} n/2 & \text{si } n \text{ pair,} \\ (n-1)/2 & \text{si } n \text{ impair,} \end{cases}$$

$$\mathrm{Y}=u_v^k v_k^{k+1}(1+(-1)^n u_k^{2(n-k-2)}) v_k^{2(n-k-3)})^{b_k},$$

$$\text{avec } b_k=\begin{cases} n/2-1 & \text{si } n \text{ pair,} \\ (n-1)/2 & \text{si } n \text{ impair,} \end{cases}$$

$$\mathrm{Z}=u_k^2 v_k^2(1+(-1)^n u_k^{2(n-k-2)} v_k^{2(n-k-3)}).$$

- -

$$\mathrm{X}=\begin{cases} u_{n-2}^{n-1}(1+v_{n-2}^2)^{n/2} & \text{(si } n \text{ pair),} \\ u_{n-2}^{n-1} v_{n-2}(v_{n-2}^2-1)^{(n-1)/2} & \text{(si } n \text{ impair),} \end{cases}$$

$$\mathrm{Y}=\begin{cases} u_{n-2}^{n-2} v_{n-2}(1+v_{n-2}^2)^{n/2-1} & \text{(si } n \text{ pair),} \\ u_{n-2}^{n-2}(v_{n-2}^2-1)^{(n-1)/2} & \text{(si } n \text{ impair),} \end{cases}$$

$$\mathrm{Z}=\begin{cases} u_{n-2}^2(1+v_{n-2}^2) & \text{(si } n \text{ pair),} \\ u_{n-2}^2(v_{n-2}^2-1) & \text{(si } n \text{ impair),} \end{cases}$$

$$X=\begin{cases}[u_{n-1}(u_{n-1}v_{n-1}^2-2i)]^{n/2}v_{n-1} & \text{si } n \text{ pair,}\\ [u_{n-1}(u_{n-1}v_{n-1}^2-2)]^{(n-1)/2}(u_{n-1}v_{n-1}^2-1) & \text{si } n \text{ impair,}\end{cases}$$

$$Y=\begin{cases}[u_{n-1}(u_{n-1}v_{n-1}^2-2i)]^{n/2-1}(u_{n-1}v_{n-1}^2-i & \text{si } n \text{ pair,}\\ [u_{n-1}(u_{n-1}v_{n-1}^2-2)]^{(n-1)/2}v_{n-1} & \text{si } n \text{ impair,}\end{cases}$$

$$Z=\begin{cases}u_{n-1}(u_{n-1}v_{n-1}^2-2i) & \text{si } n \text{ pair,}\\ u_{n-1}(u_{n-1}v_{n-1}^2-2) & \text{si } n \text{ impair,}\end{cases}$$

$$X=\begin{cases}[u_n(u_nv_n^2+2i)]^{n/2}v_n & \text{si } n \text{ pair,}\\ [u_n(u_nv_n^2+2)]^{(n-1)/2}(u_nv_n^2+1) & \text{si } n \text{ impair,}\end{cases}$$

$$Y=\begin{cases}[u_n(u_nv_n^2+2i)]^{n/2-1}(u_nv_n^2+i) & \text{si } n \text{ pair,}\\ [u_n(u_nv_n^2+2)]^{(n-1)/2} & \text{si } n \text{ impair,}\end{cases}$$

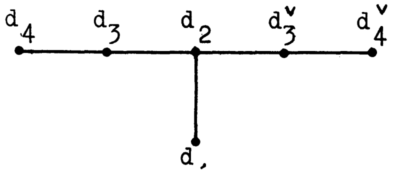
$$Z=\begin{cases}u_n(u_n v_n^2+2i) & \text{si } n \text{ pair,}\\ u_n(u_nv_n^2+2) & \text{si } n \text{ impair.}\end{cases}$$

L'application q est une désingularisation minimale de la surface S (plongée dans $\mathbb{C}^3$) d'équation $X^2=Z(Y^2+Z^{n-2})$.

6.1.3. *Type* $\mathbf{E}_6$. — Soient $\mathscr{U}_k$, $0\leqq k\leqq 4$, $\check{\mathscr{U}}_3$, $\check{\mathscr{U}}_4$ des copies de $\mathbb{C}^2$ de coordonnée (u_k, v_k), $0\leqq k\leqq 4$, $(\check{u}_3, \check{v}_3)$, $(\check{u}_4, \check{v}_4)$, respectivement. On considère la surface $\tilde{S}$ (lisse) (resp. la famille **des courbes rationnelles lisses** $\boldsymbol{d}$. **de** $\tilde{\mathbf{S}}$**) définie par les recollements (resp. par les équations) :**

$$\begin{array}{lll}
u_1=u_0^2v_0, & v_1=1/u_0, & d_1 : u_1=v_0=0,\\
u_2=u_0v_0^2, & v_2=1/v_0, & d_2 : u_2=u_0=0,\\
u_3=u_0^2(v_0+1), & v_3=1/u_0, & d_3 : u_3=v_0+1=0,\\
\check{u}_3=u_0^2(v_0-1), & \check{v}_3=1/u_0, & \check{d}_3 : \check{u}_3=v_0-1=0,\\
u_4=u_3^2v_3, & v_4=1/u_3, & d_4 : u_4=v_3=0,\\
\check{u}_4=\check{u}_3^2\check{v}_3, & \check{v}_4=1/\check{u}_3, & \check{d}_4 : \check{u}_4=\check{v}_3=0.
\end{array}$$

Chacune de ces courbes rationnelles a une auto-intersection -2, et le graphe dual associé à leur réunion est $\mathbf{E}_6$:



A l'aide des cycles définis par les diagrammes suivants :

$$C(X):\ \begin{matrix}2&4&6&4&2\\&&3&&\end{matrix},\qquad C(Y):\ \begin{matrix}2&3&4&3&2\\&&2&&\end{matrix},\qquad C(Z):\ \begin{matrix}1&2&3&2&1\\&&2&&\end{matrix}$$

on définit une application $q : \tilde{S}\rightarrow\mathbb{C}^3$ dont les restrictions aux ouverts précédents sont données par :

$$
\begin{aligned}
X &= u_0^6 v_0^3 (v_0^2-1)^4 = u_1^3 (u_1^2 v_1^4 - 1)^4 \\
&= u_2^6 v_2 (v_2^2-1)^4 = u_3^4 v_3^2 (u_3 v_3^2+1)^3 (u_3 v_3^2+2)^4 = u_4^2 (u_4^2 v_4^3+1)^3 (u_4^2 v_4^3+2)^4 \\
Y &= -u_0^4 v_0^2 (v_0^2-1)^3 = -u_1^2 (u_1^2 v_1^4-1)^3 \\
&= u_2^4 (v_2^2-1)^3 = -u_3^3 v_3^2 (u_3 v_3^2+1)^2 (u_3 v_3^2+2)^3 = -u_4^2 v_4 (u_4^2 v_4^3+1)^2 (u_4^2 v_4^3+2) \\
Z &= u_0^3 v_0^2 (v_0^2-1)^2 = u_1^2 v_1 (u_1^2 v_1^4-1)^2 \\
&= u_2^3 (v_2^2-1)^2 = u_3^2 v_3 (u_3 v_3^2+1)^2 (u_3 v_3^2+2)^2 = u_4 (u_4^2 v_4^3+1)^2 (u_4^2 v_4^3+2)^2.
\end{aligned}
$$

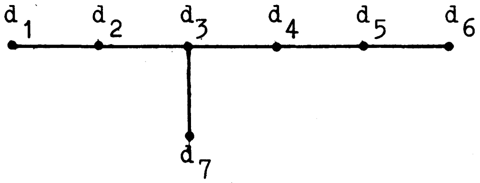
Pour l'ouvert $\check{\mathscr{U}}_3$ (resp. $\check{\mathscr{U}}_4$) on remplace u_3, v_3, $+1$, $+2$ (resp. u_4, v_4, $+1$, $+2$) dans l'expression correspondante à $\mathscr{U}_3$ (resp. à $\mathscr{U}_4$) par $\check{u}_3$, $\check{v}_3$, -1, -2 (resp. par $\check{u}_4$, $\check{v}_4$, -1, -2).

L'application q est une désingularisation minimale de la surface S (plongée dans $\mathbb{C}^3$) d'équation $X^2 = Y^3 + Z^4$.

6.1.4. *Type* $\mathbf{E}_7$. — Soient $\mathscr{U}_k$, $0 \leqq k \leqq 7$, des copies de $\mathbb{C}^2$ de coordonnées (u_k, v_k). On considère la surface $\tilde{S}$ (lisse) (resp. la famille des corbes rationnelles lisses d de $\tilde{S}$) définie par les recollements (resp. par les équations) :

$$
\begin{array}{llll}
u_k = v_{k-1} u_{k-1}^2, & v_k = 1/u_{k-1} & (1 \leqq k \leqq 6), & d_k : \ u_k = v_{k-1} = 0 \\
u_7 = (v_3+1) u_3^2, & v_7 = 1/u_3, & & d_7 : \ u_7 = v_3 + 1 = 0.
\end{array}
$$

Chacune de ces courbes rationnelles a une auto-intersection -2, et le graphe dual associé à leur réunion est $\mathbf{E}_7$:



A l'aide des cycles définis par les diagrammes suivants :

$$
C(X) : \begin{array}{cccccc} 3 & 6 & 9 & 7 & 5 & 3, \\ & & 5 & & & \end{array} \qquad
C(Y) : \begin{array}{cccccc} 2 & 4 & 6 & 5 & 4 & 3, \\ & & 3 & & & \end{array} \qquad
C(Z) : \begin{array}{cccccc} 2 & 3 & 4 & 3 & 2 & 1. \\ & & 2 & & & \end{array}
$$

On définit une application $q : \tilde{S} \to \mathbb{C}^3$ dont les restrictions aux ouverts précédents sont données par :

$$
\begin{aligned}
X &= v_0^3 (u_0^3 v_0^2+1)^5 = u_1^3 v_1^6 (u_1^2 v_1+1)^5 \\
&= u_2^6 v_2^9 (u_2+1)^5 = u_3^9 v_3^7 (1+v_3)^5 = u_4^7 v_4^5 (u_4 v_4^2+1)^5 \\
&= u_5^5 v_5^3 (u_5^2 v_5^3+1)^5 = u_6^3 v_6 (u_6^3 v_6^4+1)^5 = u_7^5 v_7 (u_7 v_7^2-1)^7,
\end{aligned}
$$

$$\begin{aligned}\mathrm{Y}&=v_0^2(u_0^3v_0^2+1)^3=u_1^2v_1^4(u_1^2v_1+1)^3\\&=u_2^4v_2^6(u_2+1)^3=u_3^6v_3^5(1+v_3)^3=u_4^5v_4^4(u_4v_4^2+1)^3\\&=u_5^4v_5^3(u_5^2v_5^3+1)^3=u_6^3v_6^2(u_6^3v_6^4+1)^3=u_7^3(u_7v_7^2-1)^5,\end{aligned}$$

$$\begin{aligned}\mathrm{Z}&=u_0v_0^2(u_0^3v_0^2+1)^2=u_1^2v_1^3(u_1^2v_1+1)^2\\&=u_2^3v_2^4(u_2+1)^2=u_3^4v_3^3(1+v_3)^2=u_4^3v_4^2(u_4v_4^2+1)^2\\&=u_5^2v_5(u_5^2v_5^3+1)^2=u_6(u_6^3v_6^4+1)^2=u_7^2(u_7v_7^2-1)^3.\end{aligned}$$

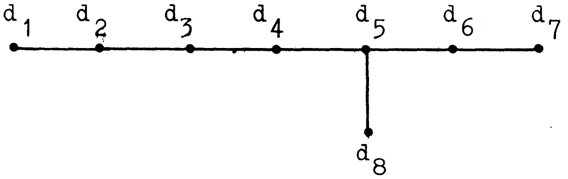
L'application q donne une résolution minimale de la surface S (plongée dans $\mathbb{C}^3$) d'équation $\mathrm{X}^2=\mathrm{Y}(\mathrm{Y}^2+\mathrm{Z}^3)$.

6.1.5. *Type* $\mathbf{E}_8$. — Soient $\mathcal{U}_k$, $0\leqq k\leqq 8$, des copies de $\mathbb{C}^2$ de coordonnées (u_k, v_k). On considère la surface $\tilde{\mathrm{S}}$ (lisse) (resp. la famille des courbes rationnelles lisses d de $\tilde{\mathrm{S}}$) définie par les recollements (resp. par les équations) :

$$u_k=v_{k-1}u_{k-1}^2,\qquad v_k=1/u_{k-1}\qquad(1\leqq k\leqq 7),\qquad d_k:\ u_k=v_{k-1}=0,$$

$$u_8=(v_5+1)u_5^2,\qquad v_8=1/u_5,\qquad d_8:\ u_8=v_5+1=0.$$

Chacune de ces courbes rationnelles a une auto-intersection -2, et le graphe dual associé à leur réunion est $\mathbf{E}_8$:



A l'aide des cycles définis par les diagrammes suivants :

$$\mathrm{C(X)}:\ \begin{matrix}3&6&9&12&15&10&5\\&&&&8&&\end{matrix},\qquad \mathrm{C(Y)}:\ \begin{matrix}2&4&6&8&10&7&4\\&&&&5&&\end{matrix}$$

$$\mathrm{C(Z)}:\ \begin{matrix}2&3&4&5&6&4&2\\&&&&3&&\end{matrix}$$

on définit une application $q:\tilde{\mathrm{S}}\to\mathbb{C}^3$ dont les restrictions aux ouverts précédents sont données par :

$$\begin{aligned}\mathrm{X}&=v_0^3(u_0^5v_0^4+1)^8=u_1^3v_1^6(u_1^4v_1^3+1)^8=u_2^6v_2^9(u_2^3v_2^2+1)^8=u_3^9v_3^{12}(u_3^2v_3+1)^8\\&=u_4^{12}v_4^{15}(u_4+1)^8=u_5^{15}v_5^{10}(v_5+1)^8=u_6^{10}v_6^5(u_6v_6^2+1)^8=u_7^5(u_7^2v_7^3+1)^8\\&=u_8^8v_8(u_8v_8^2-1)^{10},\end{aligned}$$

$$\begin{aligned}\mathrm{Y}&=v_0^2(u_0^5v_0^4+1)^5=u_1^2v_1^4(u_1^4v_1^3+1)^5=u_2^4v_2^6(u_2^3v_2^2+1)^5=u_3^6v_3^8(u_3^2v_3+1)^5\\&=u_4^8v_4^{10}(u_4+1)^5=u_5^{10}v_5^7(v_5+1)^5=u_6^7v_6^4(u_6v_6^2+1)^5=u_7^4v_7(u_7^2v_7^3+1)^5\\&=u_8^5(u_8v_8^2-1)^7,\end{aligned}$$

$$\begin{aligned}\mathrm{Z}=u_0 v_0^2(u_0^5 v_0^4+1)^3=u_1^2 v_1^3(u_1^4 v_1^3+1)^3=u_2^3 v_2^4(u_2^3 v_2^2+1)^3=u_3^4 v_3^5(u_3^2 v_3+1)^3\\ =u_4^5 v_4^6(u_4+1)^3=u_5^6 v_5^4(v_5+1)^3=u_6^4 v_6^2(u_6 v_6^2+1)^3=u_7^2(u_7^2 v_7^3+1)^3\\ =u_8^3(v_8 v_8-1)^4.\end{aligned}$$

L'application q est une désingularisation minimale de la surface S (plongée dans $\mathbb{C}^3$) d'équation $\mathrm{X}^2=\mathrm{Y}^3+\mathrm{Z}^5$.

6.2. DÉMONSTRATION DU THÉORÈME 2.2

6.2.1. *Démonstration de* (i) *: plan de la démonstration.* — Pour tout $\rho\in\mathrm{Irr}(\mathrm{G})$, considérons le fibré $\mathscr{F}_\rho$ (défini en paragraphe 2.7). On a $(rg\,\mathscr{F}_\rho, c_1(\mathscr{F}_\rho))=\pi(\rho)$ (prop. 1.2, cor. 2.9).

Nous allons montrer, cas par cas, qu'il existe un et un seul $d_\rho\in\mathrm{Irr}(\mathrm{D})$ tel que $\deg(\mathscr{F}_\rho|_{d_\rho})=1$ et $\deg(\mathscr{F}_\rho|_d)=0$ pour $d\neq d_\rho$, $d\in\mathrm{Irr}(\mathrm{D})$. Par inspection on vérifiera que $\rho\mapsto d_\rho$ est bijective et que $(d_{\rho_i}.\,d_{\rho_j})=a_{ij}$ pour $\rho_i\neq\rho_j$. On aura donc $c_1(\mathscr{F}_\rho)=b_{d_\rho}$ ce qui achèvera la démonstration de (i).

Le fibré $\mathscr{F}_\rho$ s'obtient en annulant la torsion de $q^*\mathscr{M}_\rho$, torsion qui est à support dans D. On a une résolution (induite par celle de 4.6) :

$$\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\mathscr{S}}\xrightarrow{\mathrm{T}_\rho^-}\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\mathscr{S}}\to\mathscr{M}_\rho\to 0$$

d'où une suite exacte sur $\tilde{\mathscr{S}}$:

$$\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\tilde{\mathscr{S}}}\xrightarrow{\tilde{\mathrm{T}}_\rho^-}\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\tilde{\mathscr{S}}}\to q^*\mathscr{M}_\rho\to 0$$

et par suite un homomorphisme surjectif :

$$\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\tilde{\mathscr{S}}}\xrightarrow{\overline{\varpi}_\rho}\mathscr{F}_\rho\to 0.$$

Les modules $\mathscr{M}_\rho$ sont des $\mathcal{O}_{\tilde{\mathscr{S}}}$-modules libres, et les homomorphismes $\mathrm{T}_\rho^-=\theta_\rho\otimes\mathrm{Id}_{\mathcal{O}_{\tilde{\mathscr{S}}}}-\mathrm{Id}_{\mathscr{M}_\rho}\otimes\mathrm{X}$ ont été décrits par des matrices (§ 5.5).

Sur chaque ouvert $\mathscr{U}_k$ de $\tilde{\mathscr{S}}$ on va décrire un sous-module libre L_k de $(\mathscr{M}_\rho\underset{\mathcal{O}_{\mathscr{S}'}}{\otimes}\mathcal{O}_{\tilde{\mathscr{S}}})|_{\mathscr{U}_k}$ tel que la projection $\varpi_\rho|_{\mathscr{U}_k}$ induise un isomorphisme de L_k sur L_k sur $\mathscr{F}_\rho|_{\mathscr{U}_k}$.

Le $c_1(\mathscr{F}_\rho)$ s'obtient alors en examinant les diviseurs sur D des matrices de changement de base de L_k à $\mathrm{L}_{k'}$, sur $\mathscr{U}_k\cap\mathscr{U}_{k'}$. Comme on connait explicitement les matrices décrivant T_ρ^- et l'application $q|_{\mathscr{U}_k}:\mathscr{U}_k\to\mathscr{S}$, le calcul est purement mécanique. On se bornera donc à traiter l'exemple de $\mathbf{A}_n$ et l'exemple de la représentation ρ_5 de $\mathbf{E}_8$ (correspondant au sommet central de $\mathbf{E}_8$).

6.2.2. *Démonstration de* (i), *type* $\mathbf{A}_n(n\geqq 1)$. — Soit j un entier, $1\leqq j\leqq n$. En vue de la définition de $q|_{\mathscr{U}_k}$ (*voir* § 6.1.1) on a $q^*\overline{\mathrm{Z}}^j|_{\mathscr{U}_k}=u_k^j v_k^j$, $q^*\overline{\mathrm{Y}}|_{\mathscr{U}_k}=u_k^k v_k^{k+1}$, $0\leqq k\leqq n$. Par conséquent, si $k \geqq j$, $q^* \overline{Z}^j |_{\mathscr{U}_k}$ divise $q^* \overline{Y} |_{\mathscr{U}_k}$, et si $k<j$, $q^* \overline{Y} |_{\mathscr{U}_k}$ divise $q^* \overline{Z}^j |_{\mathscr{U}_k}$; et par suite le $\mathscr{O}_{\mathscr{U}_k}$-module $\mathscr{F}_{\rho_j} |_{\mathscr{U}_k}$ est isomorphe au module libre de rang 1, L_k, engendré par :

$$\begin{array}{lll} s_1(j) & \text{si} & k \geqq j, \\ s_2(j) & \text{si} & k<j \end{array}$$

(*voir* § 5.5.1).

On a donc $\deg \mathscr{F}_{\rho_j} |_{d_k} = 0$ si $k \neq j$, $1 \leqq k \leqq n$, car les changements de base sur $\mathscr{U}_{k-1} \cap \mathscr{U}_k$ sont triviaux, et $\deg \mathscr{F}_{\rho_j} |_{d_j} = 1$, car le changement de base sur $\mathscr{U}_{j-1} \cap \mathscr{U}_j$ est : $s_2(j) = v_j s_1(j)$. Par suite $d_{\rho_j} = d_j$, $1 \leqq j \leqq n$, et $(d_i . d_j) = a_{ij}$, $1 \leqq i \neq j \leqq n$, d'où (i).

6.2.3. *Cas* ρ_5, *type* $\mathbf{E}_8$. — Avec la décomposition $M_{\rho_5} = M_{\rho'_5} \oplus M_{\varepsilon\rho'_5}$, l'homomorphisme $T^-_{\rho_5}$ est de la forme :

$$\begin{bmatrix} [-X \, \mathrm{Id}_{M_{\rho'_5}}] & [\theta_{\varepsilon\rho'_5}] \\ [\theta_{\rho'_5}] & [-X \, \mathrm{Id}_{M_{\varepsilon\rho'_5}}] \end{bmatrix}$$

où $[\theta_{\rho'_5}]$ et $[\theta_{\varepsilon\rho'_5}]$ ont été décrites en paragraphe 5.5.5 avec des bases qu'on notera de la façon suivante : $(s_1, s_2, s_3, s_4, s_5, s_6)$ pour $M_{\rho'_5}$ et $(s_7, s_8, s_9, s_{10}, s_{11}, s_{12})$ pour $M_{\varepsilon\rho'_5}$ où les s_i, $1 \leqq i \leqq 12$, sont homogènes de degrés (5, 9, 13, 17, 21, 25) et (7, 11, 15, 15, 19, 23) respectivement (§ 5.3.5).

Nous allons montrer que le $\mathscr{O}_{\mathscr{U}_k}$-module $\mathscr{F}_{\rho_5} |_{\mathscr{U}_k}$ est isomorphe au module libre de rang 6, L_k, engendré par :

$$\begin{array}{lll} s_1, s_2, s_3, s_7, s_8, s_9 & \text{si} & 0 \leqq k \leqq 4, \\ s_1, s_2, s_3, s_7, s_8, s_{10} & \text{si} & 5 \leqq k \leqq 8. \end{array}$$

Notons c_i la colonne correspondante à $T^-_{\rho_5}(s_i)$, $1 \leqq i \leqq 12$,de la matrice associée à $T^-_{\rho_5}$ avec les bases précédentes. Par abus de notation on écrira, dans ce paragraphe, X, Y, Z, à la place de $q^* X$, $q^* Y$, $q^* Z$, respectivement. En vue de la définition du morphisme de désingularisation q (§ 6.1.5) on a :

Sur $\mathscr{U}_0$, $\mathscr{U}_1$: X divise c_4, c_5, c_6, c_{10}, et Y divise c_2, c_3, d'où on peut éliminer s_4, s_5, s_6, s_{10} et s_{11}, s_{12} respectivement.

Sur $\mathscr{U}_2$, $\mathscr{U}_3$, $\mathscr{U}_4$: X divise c_4, c_5, c_6, et Y divise c_2, c_3; d'où on peut éliminer s_4, s_5, s_6 et s_{11}, s_{12} respectivement. Par ailleurs Z^2 divise c_{10}, donc on peut former une combinaison linéaire de la forme $c_{10}/Z^2 + \star c_5/X$ qui soit divisible par X/Z^2, d'où on peut éliminer s_{10}.

Sur $\mathscr{U}_5$, $\mathscr{U}_6$: par les mêmes propriétés de divisibilité que pour $\mathscr{U}_2$, $\mathscr{U}_3$, $\mathscr{U}_4$, on peut éliminer s_4, s_5, s_6, s_{11}, s_{12}. Or la combinaison linéaire $c_1/Z^2 + \star c_5/X$ précédente est divisible par Z^3/X, d'où on peut éliminer s_9.

Sur $\mathscr{U}_7$: Z divise c_1, c_7 et Z^2 divise c_2, c_3, c_8, c_9; d'où on peut éliminer s_{12}, s_6 et s_9, s_{11}, s_4, s_5 respectivement.

Sur $\mathscr{U}_8$: Y divise c_2, c_3, c_8, c_9 et YZ divise c_4, d'où on peut éliminer s_{11}, s_{12}, s_5, s_6 et s_9 respectivement. Par ailleurs Z^2 divise c_{10}, donc on peut former une combinaison linéaire de la forme $c_{10}/Z^2 + \star c_8/Y$ qui soit divisible par Z^2/Y, d'où on peut éliminer s_9.

La discussion précédente montre que la projection $\varpi_{\rho_5}|_{\mathscr{U}_5}$ induit un homomorphisme surjectif de L_k sur $\mathscr{F}_{\rho_5}|_{\mathscr{U}_k}$; l'injectivité résulte du corollaire 2.10(ii).

Finalement, on a $\deg \mathscr{F}_{\rho_5}|_{d_k}=0$ si $k\neq 5$, $1\leqq k\leqq 8$, car les changements de base sur $\mathscr{U}_{k-1}\cap\mathscr{U}_k$ $(k\neq 5,\ 1\leqq k\leqq 7)$ et sur $\mathscr{U}_8\cap\mathscr{U}_5$ sont triviaux; et $\deg \mathscr{F}_{\rho_5}|_{d_5}=1$, parce que sur $\mathscr{U}_4\cap\mathscr{U}_5$ on a la relation :

$$s_9=\star(v_5+1)\,s_{10}+f(s_1,\ s_2,\ s_3,\ s_7,\ s_8)$$

où f est une combinaison linéaire à coefficients dans $\mathscr{O}_{\mathscr{U}_5}$, et où (v_5+1) provient de la restriction à $\mathscr{U}_5$ du quotient X^2/Z^5.

6.2.4. *Fin de la démonstration.* — La représentation canonique c est (avec les notations de paragraphe 3.7) $\rho_1\oplus\rho_n$ pour le type $\mathbf{A}_n (n\geqq 1)$, ρ_2 pour le type $\mathbf{D}_n (n\geqq 4)$, et ρ_1 pour les types $\mathbf{E}_6$, $\mathbf{E}_7$, $\mathbf{E}_8$. Avec les notations de paragraphe 6.1 pour les composantes irréductibles du diviseur D on trouve dans la démonstration de (i) :

$$\pi(c)=\begin{cases}(2,\ b_{d_1}+b_{d_n}) \text{ pour le type } \mathbf{A}_n & (n\geqq 1),\\ (2,\ b_{d_2}) \text{ pour le type } \mathbf{D}_n & (n\geqq 4),\\ (2,\ b_{d_1}) \text{ pour les types } \mathbf{E}_6,\ \mathbf{E}_7,\ \mathbf{E}_8.\end{cases}$$

Par ailleurs, le cycle fondamental $\mathscr{Z}$ est égal à $\sum_{k=1}^{n} d_k$ pour le type $\mathbf{A}_n$, et il est représenté par les diagrammes suivants pour les autres types :

Type	$\mathscr{Z}$
$\mathbf{D}_n (n\geqq 4)$	$\begin{array}{cccc} & & & 1\\ 1 & 2\ldots & 2 & \\ & & & 1\end{array}$
$\mathbf{E}_6$	$\begin{array}{ccccc}1&2&3&2&1\\ &&2&&\end{array}$
$\mathbf{E}_7$	$\begin{array}{cccccc}2&3&4&3&2&1\\ &&2&&&\end{array}$
$\mathbf{E}_8$	$\begin{array}{ccccccc}2&3&4&5&6&4&2\\ &&&&3&&\end{array}$

On vérifie donc, avec les conventions de paragraphe 1.1, les égalités dans $K(\mathscr{S})$:

$$(\mathscr{Z})=\begin{cases}(0,\ -b_{d_1}-b_{d_n}) \text{ pour le type } \mathbf{A}_n & (n\geqq 1),\\ (0,\ -b_{d_2}) \text{ pour le type } \mathbf{D}_n & (n\geqq 4),\\ (0,\ -b_{d_1}) \text{ pour les types } \mathbf{E}_6,\ \mathbf{E}_7,\ \mathbf{E}_8.\end{cases}$$

Par conséquent on a (dans tous les cas) l'égalité :

$$\pi(2-c)=[\mathscr{Z}].$$

Par ailleurs, on a, pour $i\neq 0$:

$$(c-2)\,\rho_i=\sum_j a_{ij}\,\rho_j-2\,\rho_i$$

d'où :

$$\pi((c-2)\,\rho_i)=(0,\ \sum_{j>0} a_{ij}\,\rho_j-2\,\rho_i).$$

Or l'élément e_{d_i} de $\mathrm{Pic}_{\mathrm{D}}(\tilde{\mathscr{S}})$ s'exprime dans la base $\{b_d\}$ de $\mathrm{Pic}(\tilde{\mathscr{S}})$ de la façon suivante :

$$e_{d_i}=\sum_{j>0} a_{ij}\,b_{d_j}-2\,b_{d_i}$$

où on a d_i à la place de d_{ρ_i}. Par suite de ce qui précède et de la proposition 1.2(iii), on a :

$$\pi((c-2)\,\rho_i)=[d_{\rho_i}],\qquad \forall\, i>0,$$

d'où l'assertion (ii).

L'assertion (i) et le fait que $\pi(\rho_0)=(1,0)$ impliquent (iii). L'assertion (iv) résulte immédiatement de la dernière partie de (ii). L'assertion (v) est conséquence du fait que $\mathrm{R(G)}/(2-c)\,\mathrm{R(G)}$ est isomorphe à $\tilde{\mathrm{K}}^{\mathrm{G}}(\mathscr{V}-\{0\})$ (*voir* § 1.5), et du fait que

$$q^{-1}\circ p|_{\mathscr{V}-\{0\}} : \mathscr{V}-\{0\}\to\tilde{\mathscr{S}}-\mathrm{D}$$

est un morphisme étale, ce qui achève la démonstration du théorème.

7. Corollaire : Caractérisation de la désingularisation minimale

Soit $\mathscr{V}$ *le germe de* $\mathbb{C}^2$ *à l'origine,* G *un sous-groupe fini de* $\mathrm{SL}(2,\mathbb{C})$ *qui agit librement sur* $\mathscr{V}-\{0\}$; $p:\mathscr{V}\to\mathscr{S}=\mathscr{V}/\mathrm{G}$ *le morphisme quotient. Alors la désingularisation minimale* $q:\tilde{\mathscr{S}}\to\mathscr{S}$ *est le platificateur normal minimal de* $\mathscr{V}$ *sur* $\mathscr{S}$.

Démonstration. — Soit $\bar{q}:\mathscr{P}\to\mathscr{S}$ le platificateur normal minimal de $\mathscr{V}$ sur $\mathscr{S}$. En vertu de la proposition 2.4 on sait que $q:\tilde{\mathscr{S}}\to\mathscr{S}$ est un platificateur de $\mathscr{V}$ sur $\mathscr{S}$, qui de plus est normal car $\tilde{\mathscr{S}}$ est lisse. Par suite, le morphisme q se factorise par $\mathscr{P}$, i. e. on a un diagramme commutatif :

$$\begin{tikzcd}
\tilde{\mathscr{S}} \arrow[dr, "\sigma"] \arrow[dd, "q"'] & \\
& \mathscr{P} \arrow[dl, "\bar{q}"] \\
\mathscr{S} &
\end{tikzcd}$$

Par minimalité, le morphisme σ est un isomorphisme en dehors du diviseur exceptionnel $\mathrm{D}\subset\tilde{\mathscr{S}}$. Nous allons montrer que, en fait, σ est un isomorphisme. S'il ne l'est pas, alors, en vertu de la normalité de $\mathscr{P}$ il contracte un sous-diviseur $\mathrm{D}^c\subset\mathrm{D}$, i. e. $\sigma(\mathrm{D}^c)$ est de dimension zéro. Soit ρ une représentation irréductible de G dans un $\mathbb{C}$-espace vectoriel E_ρ. Posons $\overline{\mathscr{F}}_\rho=\bar{q}^*\mathscr{M}_\rho/\mathrm{Tors}_{\mathscr{P}}$ où $\mathscr{M}_\rho=\mathrm{Hom}_{\mathbb{C}[\mathrm{G}]}(\mathrm{E}_\rho,\mathscr{O}_{\mathscr{V}})$; on a :

$$\mathscr{O}_{\mathscr{V}}=\bigoplus_{\rho}(\mathscr{M}_\rho\otimes_{\mathbb{C}}\mathrm{E}_\rho)\qquad\text{d'où}\quad \bar{q}^*\mathscr{O}_{\mathscr{V}}/\mathrm{Tors}_{\mathscr{P}}=\bigoplus_{\rho}(\overline{\mathscr{F}}_\rho\otimes_{\mathbb{C}}\mathrm{E}_\rho).$$

Par conséquent, $\overline{\mathscr{F}}_{\rho}$ est localement libre car $\mathscr{P}$ est un platificateur de $\mathscr{V}$ sur $\mathscr{S}$. De même, le $\mathscr{O}_{\tilde{\mathscr{S}}}$-module $\mathscr{F}_{\rho}=q^{*}\mathscr{M}_{\rho}/\mathrm{Tors}_{\tilde{\mathscr{S}}}$ est localement libre, et par la commutativité du diagramme précédent on a :

$$\sigma^{*}\overline{\mathscr{F}}_{\rho}=\mathscr{F}_{\rho}.$$

Soit ρ telle que la composante irréductible d_{ρ} de D (th. 2.2) soit contractée par σ, i. e. telle que $d_{\rho}\subset D^{c}$. Alors on a une contradiction, car d'une part la restriction de $\mathscr{F}_{\rho}$ à d_{ρ} est non triviale [car $(c_1(\mathscr{F}_{\rho}).d_{\rho})=1$], et d'autre part $\overline{\mathscr{F}}_{\rho}$ est libre au voisinage du point $\sigma(d_{\rho})\in\mathscr{P}$, et par suite $\sigma^{*}\overline{\mathscr{F}}_{\rho}$ est trivial au voisinage de d_{ρ}. Par conséquent D^{c} est vide et σ est un isomorphisme.

Introduction to the monster Lie algebra.

Groups, Combinatorics, and geometry, p. 99–107, edited by M. W. Liebeck and J. Saxl, L.M.S. lecture note series 165, C.U.P. 1992.

Richard E. Borcherds,

I would like to thank J. M. E. Hyland for suggesting many improvements to this paper.

The monster sporadic simple group, of order

$$2^{46}3^{20}5^{9}7^{6}11^{2}13^{3}17.19.23.29.31.41.47.59.71,$$

acts on a graded vector space $V=\oplus_{n\in\mathbf{Z}}V_n$ constructed by Frenkel, Lepowsky and Meurman [Fre] The dimension of V_n is equal to the coefficient $c(n)$ of the elliptic modular function

$$j(\tau)-744=\sum_n c(n)q^n=q^{-1}+196884q+21493760q^2+\cdots$$

(where we write q for $e^{2\pi i\tau}$, and $\mathrm{Im}(\tau)>0$). The main problem is to describe V as a graded representation of the monster, or in other words to calculate the trace $\mathrm{Tr}(g|V_n)$ of each element g of the monster on each space V_n. The best way to describe this information is to define the Thompson series

$$T_g(q)=\sum_{n\in\mathbf{Z}}\mathrm{Tr}(g|V_n)q^n$$

for each element g of the monster, so that our problem is to work out what these Thompson series are. For example, if 1 is the identity element of the monster then $\mathrm{Tr}(1|V_n)=\dim(V_n)=c(n)$, so that the Thompson series $T_1(q)=j(\tau)-744$ is the elliptic modular function. McKay, Thompson, Conway and Norton conjectured [Con] that the Thompson series $T_g(q)$ are always Hauptmoduls for certain modular groups of genus 0 (I will explain what this means in a moment.) In this paper we describe the proof of this in [Bor] using an infinite dimensional Lie algebra acted on by the monster called the monster Lie algebra. These Hauptmoduls are known explicitly, so this gives a complete description of V as a representation of the monster.

We now recall the definition of a Hauptmodul. The group $SL_2(\mathbf{Z})$ acts on the upper half plane $H=\{\tau\in\mathbf{C}|\mathrm{Im}(\tau)>0\}$ by $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)(\tau)=\frac{a\tau+b}{c\tau+d}$. The elliptic modular function $j(\tau)$ is more or less the simplest function defined on H that is invariant under $SL_2(\mathbf{Z})$ in much the same way that the function $e^{2\pi i\tau}$ is the simplest function invariant under $\tau\mapsto\tau+1$. The element $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ of $SL_2(\mathbf{Z})$ takes τ to $\tau+1$, so in particular $j(\tau)$ is periodic and can be written as a Laurent series in $q=e^{2\pi i\tau}$. The exact expression for j is

$$j(\tau)=\frac{(1+240\sum_{n>0}\sigma_3(n)q^n)^3}{q\prod_{n>0}(1-q^n)^{24}}$$

where $\sigma_3(n)=\sum_{d|n}d^3$ is the sum of the cubes of the divisors of n; see any book on modular forms or elliptic functions, for example [Ser]. Another way of thinking about j is that it is an isomorphism from the quotient space $H/SL_2(\mathbf{Z})$ to the complex plane, which can be thought of as the Riemann sphere minus the point at infinity.

There is nothing particularly special about the group $SL_2(\mathbf{Z})$ acting on H. We can consider functions invariant under any group G acting on H, for example some group G of finite index in $SL_2(\mathbf{Z})$. If G satisfies some mild conditions then the quotient H/G will again be a compact Riemann surface with a finite number of points removed. If this compact Riemann surface is a sphere, rather than something of higher genus, then we say that G is a genus 0 group. When this happens there is a more or less unique map from H/G to the complex plane $\mathbf{C}$, which induces a function from H to $\mathbf{C}$ which is invariant under the group G acting on H. When this function is correctly normalized it is called a Hauptmodul for the genus 0 group G. For example, $j(\tau) - 744$ is the Hauptmodul for the genus 0 group $SL_2(\mathbf{Z})$.

For example, we could take G to be the group $\Gamma_0(2)$, where $\Gamma_0(N) = \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbf{Z}) | c \equiv 0 \bmod N\}$. The quotient H/G is then a sphere with 2 points removed, so that G is a genus 0 group. Its Hauptmodul starts off $T_{2-}(q) = q^{-1} + 276q - 2048q^2 + \cdots$, and is equal to the Thompson series for a certain element of the monster of order 2 (of type 2B in atlas notation). Similarly $\Gamma_0(N)$ is a genus 0 subgroup for several other values of N which correspond to elements of the monster. (However the genus of $\Gamma_0(N)$ tends to infinity as N increases, so there are only a finite number of integers N for which it has genus 0; more generally Thompson has shown that there are only a finite number of conjugacy classes of genus 0 subgroups of $SL_2(\mathbf{R})$ which are commensurable with $SL_2(\mathbf{Z})$.) The first person to notice any connection between the monster and genus 0 subgroups of $SL_2(\mathbf{R})$ was probably Ogg, who observed that the primes p for which the normalizer of $\Gamma_0(p)$ in $SL_2(\mathbf{R})$ has genus 0 are exactly those which divide the order of the monster.

So the problem we want to solve is to calculate the Thompson series $T_g(\tau)$ and show that they are Hauptmoduls of genus 0 subgroups of $SL_2(\mathbf{R})$. The difficulty with doing this is as follows. Frenkel, Lepowsky, and Meurman constructed V as the sum of two subspaces V^+ and V^-, which are the $+1$ and -1 eigenspaces of an element of order 2 in the monster. If an element g of the monster commutes with this element of order 2, then it is not difficult to to work out its Thompson series $T_g(q) = \sum_n \mathrm{Tr}(g|V_n)q^n$ as the sum of two series given by its traces on V^+ and V^- and it would be tedious but straightforward to check that these all gave Hauptmoduls. However if an element of the monster is not conjugate to something that commutes with this element of order 2 then there is no obvious direct way of working out its Thompson series, because it muddles up V^+ and V^- in a very complicated way.

We now give a bird's eye view of the rest of this paper. We first construct a Lie algebra from V, called the monster Lie algebra. This is a generalized Kac-Moody algebra, so we recall some facts about such algebras, and in particular show how each such algebra gives an identity called its denominator formula. A well known example of this is that the denominator formulas of affine Kac-Moody algebras are the Macdonald identities. The denominator formula for the monster Lie algebra turns out to be the product formula for the elliptic modular function j, and we use this to work out the structure of the monster Lie algebra, and in particular to find its "simple roots". Once we know the simple roots, we can write down a sort of twisted denominator formula for each element of the monster group. These twisted denominator formulas imply some relations between the coefficients of the Thompson series of the monster, which are strong enough to characterize them and verify that they are indeed Hauptmoduls.

We now introduce the the monster Lie algebra. This is a $\mathbf{Z}^2$-graded Lie algebra, whose piece of degree $(m,n) \in \mathbf{Z}^2$ is isomorphic as a module over the monster to V_{mn} if $(m,n) \neq (0,0)$ and to $\mathbf{R}^2$ if $(m,n) = (0,0)$, so for small degrees it looks something like

$$\begin{array}{ccccccccc}
 & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
\cdots & 0 & 0 & 0 & 0 & V_3 & V_6 & V_9 & \cdots \\
\cdots & 0 & 0 & 0 & 0 & V_2 & V_4 & V_6 & \cdots \\
\cdots & 0 & 0 & V_{-1} & 0 & V_1 & V_2 & V_3 & \cdots \\
\cdots & 0 & 0 & 0 & \mathbf{R}^2 & 0 & 0 & 0 & \cdots. \\
\cdots & V_3 & V_2 & V_1 & 0 & V_{-1} & 0 & 0 & \cdots \\
\cdots & V_6 & V_4 & V_2 & 0 & 0 & 0 & 0 & \cdots \\
\cdots & V_9 & V_6 & V_3 & 0 & 0 & 0 & 0 & \cdots \\
 & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots &
\end{array}$$

This is a very big Lie algebra because the dimension of V_n increases exponentially fast; most infinite dimensional Lie algebras that occur in mathematics can be graded so that the dimensions of the graded pieces have only polynomial growth.

Very briefly, the construction of this Lie algebra goes as follows (this construction is not used later, so it does not matter if the reader finds this meaningless). The graded vector space V is a vertex algebra; roughly speaking this means that V has an infinite number of products on it which satisfy some rather complicated identities. (The Griess product on the 196884 dimensional space V_1 is a special case of one of the vertex algebra products.) We can also construct a vertex algebra from any even lattice, and the tensor product of two vertex algebras is a vertex algebra. We take the tensor product of the monster vertex algebra V with that of the two dimensional even Lorentzian lattice (defined by the matrix $\left(\begin{smallmatrix}0,1\\1,0\end{smallmatrix}\right)$) to get a new vertex algebra W. The monster Lie algebra is then the space of physical states of the vertex algebra W; this is a subquotient of W, which is roughly a space of highest weight vectors for an action of the Virasoro algebra on W. The subquotient can be identified exactly using the no-ghost theorem from string theory, and turns out to be as described above.

We need to know what the structure of the monster Lie algebra is. It turns out to be something called a generalized Kac-Moody algebra, so we will now have a digression to explain what these are.

To motivate Kac-Moody algebras we first look at the structure of finite dimensional simple Lie algebras. A typical finite dimensional Lie algebra is $sl_4(\mathbf{R})$, the algebra of 4×4 matrices of trace 0 with bracket given by $[a,b] = ab - ba$. If we look at this Lie algebra we see that it has three subalgebras $sl_2(\mathbf{R})$ as indicated below (as well as many others):

$$\begin{pmatrix} * & * & & \\ * & * & & \\ & & & \\ & & & \end{pmatrix}, \begin{pmatrix} & & & \\ & * & * & \\ & * & * & \\ & & & \end{pmatrix}, \begin{pmatrix} & & & \\ & & & \\ & & * & * \\ & & * & * \end{pmatrix}.$$

The Dynkin diagram of $sl_4(\mathbf{R})$ is constructed by drawing a point for each of these sl_2's, and connecting them by various numbers of lines depending on how the sl_2's are arranged; for example, if the two sl_2's commute then we draw no lines between the corresponding points, and if the sl_2's overlap in one corner we draw a single line between the points. The Dynkin diagram of sl_4 is therefore $\bullet - \bullet - \bullet$, where the two outer dots are not joined because the corresponding sl_2's of sl_4 commute, and so on. Conversely we can reconstruct sl_4 from its Dynkin diagram by writing down some generators and relations from the Dynkin diagram. Roughly speaking, sl_4 is generated by an sl_2 for each point of the Dynkin diagram together with some relations depending on the lines between points; for example, if two points are not joined we add relations saying that the corresponding sl_2's commute. We can construct all other finite dimensional split semisimple Lie algebras from their Dynkin diagrams (usually denoted by A_n, B_n, C_n, D_n, E_6, E_7, E_8, F_4, and G_2) in a similar way. If we are given some graph which is not one of these Dynkin diagrams of finite dimensional Lie algebras we can still write down generators and relations; the main difference is that these Lie algebras will be infinite dimensional rather than finite dimensional. We can think of a Kac-Moody algebra as a Lie algebra generated by a copy of sl_2 for each point of its Dynkin diagram.

The simplest example of an infinite dimensional Kac-Moody algebra is the Lie algebra $sl_2(\mathbf{R}[z,z^{-1}])$ of 2×2 matrices whose entries are Laurent polynomials. (This is a slight simplification; the Kac-Moody algebra is really a central extension of this Lie algebra, but we will ignore this.) The Dynkin diagram is $\bullet = \bullet$, so this algebra is generated by 2 copies of $sl_2(\mathbf{R})$, which are the subalgebras of elements of the form $\left(\begin{smallmatrix} a,b \\ c,-a \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} a,bz \\ cz^{-1},-a \end{smallmatrix}\right)$. The algebra $sl_2(\mathbf{R}[z,z^{-1}])$ can be $\mathbf{Z}^2$-graded by letting $\left(\begin{smallmatrix} 0,z^n \\ 0,0 \end{smallmatrix}\right)$ have degree $(2n+1,1)$, letting $\left(\begin{smallmatrix} z^n,0 \\ 0,-z^n \end{smallmatrix}\right)$ have degree (2n,0), and letting $\left(\begin{smallmatrix} 0,0 \\ z^n,0 \end{smallmatrix}\right)$ have degree $(2n-1,-1)$. The picture we get looks like

$$\begin{array}{ccccccccc}
\cdots\begin{pmatrix} 0 & 0 \\ z^{-2} & 0 \end{pmatrix} & & \begin{pmatrix} 0 & 0 \\ z^{-1} & 0 \end{pmatrix} & & \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} & & \begin{pmatrix} 0 & 0 \\ z & 0 \end{pmatrix}\cdots \\
\cdots & \begin{pmatrix} z^{-1} & 0 \\ 0 & -z^{-1} \end{pmatrix} & & \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} & & \begin{pmatrix} z & 0 \\ 0 & -z \end{pmatrix} & \cdots \\
\cdots\begin{pmatrix} 0 & z^{-1} \\ 0 & 0 \end{pmatrix} & & \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} & & \begin{pmatrix} 0 & z \\ 0 & 0 \end{pmatrix} & & \begin{pmatrix} 0 & z^2 \\ 0 & 0 \end{pmatrix}\cdots
\end{array}$$

where on each point of $\mathbf{Z}^2$ we have written something that spans the corresponding subspace of the Lie algebra.

We now describe the denominator formula of Kac-Moody algebras, and as an example show that for the Lie algebra $sl_2(\mathbf{R}[z,z^{-1}])$ it becomes the Jacobi triple product identity. The characters $Ch(V)$ of finite dimensional irreducible representations V of finite dimensional simple Lie algebras are described by the Weyl character formula

$$Ch(V) = \frac{\sum_{w\in W}\det(w)e^{w(\lambda-\rho)}}{e^{-\rho}\prod_{\alpha>0}(1-e^{\alpha})^{\mathrm{mult}(\alpha)}}$$

and the same formula turns out to be true for the characters of lowest weight representations of Kac-Moody algebras. The only case we will use this is when V is the trivial one dimensional representation with character 1, when the character formula becomes the denominator formula

$$e^{-\rho}\prod_{\alpha>0}(1-e^{\alpha})^{\mathrm{mult}(\alpha)}=\sum_{w\in W}\det(w)e^{-w(\rho)}.$$

Rather than explain precisely what all the terms in this formula mean, we will just describe them in the case of $sl_2(\mathbf{R}[z,z^{-1}])$. The product is over the "positive roots" α; for $sl_2(\mathbf{R}[z,z^{-1}])$ these are the vectors $\alpha=(m,n)$ with $m>0$ for which there is something in $sl_2(\mathbf{R}[z,z^{-1}])$ of that degree, in other words the vectors $(2m,0)$, $(2m-1,1)$, and $(2m-1,-1)$ for $m>0$. The multiplicity $\mathrm{mult}(\alpha)$ is the dimension of the subspace of that degree, which for $sl_2(\mathbf{R}[z,z^{-1}])$ is always 1. If we put $e^{(m,n)}=x^m y^n$, then the product becomes

$$\prod_{m>0}(1-x^{2m})(1-x^{2m-1}y)(1-x^{2m-1}y^{-1}).$$

The sum is a sum over all elements of the "Weyl group" W, which is a reflection group generated by one reflection for each point of the Dynkin diagram. In this case the Weyl group is the infinite dihedral group, which has an infinite cyclic subgroup of index 2, so the sum over the Weyl group is essentially a sum over the integers $\mathbf{Z}$. If we work out explicitly what it is, the Weyl denominator formula becomes

$$\prod_{m>0}(1-x^{2m})(1-x^{2m-1}y)(1-x^{2m-1}y^{-1})=\sum_{n\in\mathbf{Z}}(-1)^n x^{n^2}y^n.$$

which is the Jacobi triple product identity.

Not surprisingly, we can do the same with sl_2 replaced by any other simple finite dimensional Lie algebra, and we then obtain some identities called the Macdonald identities. (In fact there is more than one Macdonald identity for some finite dimensional Lie algebras, because there are sometimes ways of "twisting" this construction.)

Generalized Kac-Moody algebras are rather like Kac-Moody algebras except that we are allowed to glue together the sl_2's in more complicated ways, and are also allowed to use Heisenberg Lie algebras as well as sl_2's to generate the algebra. In technical terms, the roots of a Kac-Moody algebra may be either real (norm >0) or imaginary (norm ≤ 0) but all the simple roots must be real. Generalized Kac-Moody algebras may also have imaginary simple roots. They have a denominator formula which is similar to the one above, except that it has some extra correction terms corresponding to the imaginary simple roots. (The simple roots of a generalized Kac-Moody algebra correspond to a minimal set of generators for the subalgebra corresponding to the positive roots; for example, the simple roots of $sl_2(\mathbf{R}[z,z^{-1}])$ are $(1,1)$ and $(1,-1)$. For Kac-Moody algebras the simple roots also correspond to the points of the Dynkin diagram and to the generators of the Weyl group.)

We now return to the monster Lie algebra. This is a generalized Kac-Moody algebra, and we are going to write down its denominator formula, which says that a product over the positive roots is a sum over the Weyl group. The positive roots are the vectors (m,n) with $m>0$, $n>0$, and the vector $(1,-1)$, and the root (m,n) has multiplicity $c(mn)$. The Weyl group has order 2 and its nontrivial element maps (m,n) to (n,m), so it exchanges

$p = e^{(1,0)}$ and $q = e^{(0,1)}$. The denominator formula is the product formula for the j function

$$p^{-1}\prod_{m>0,n\in\mathbf{Z}}(1-p^mq^n)^{c(mn)} = j(p)-j(q).$$

(The left side is apparently not antisymmetric in p and q but in fact it is because of the factor of $p^{-1}(1-p^1q^{-1})$ in the product.) The reason why we get $j(p)$ and $j(q)$ rather than just a monomial in p and q on the right hand side (as we would for ordinary Kac-Moody algebras) is because of the correction due to the imaginary simple roots of M. The simple roots of M correspond to a set of generators of the subalgebra E of the elements of M whose degree is to the right of the y axis (so the roots of E are the positive roots of M), and turn out to be the vectors $(1,n)$ each with multiplicity $c(n)$. In the picture of the monster Lie algebra given earlier, the simple roots are given by the column just to the right of the one containing $\mathbf{R}^2$. The sum of the simple root spaces is isomorphic to the space V. The simple root $(1,-1)$ is real of norm 2, and the simple roots $(1,n)$ for $n>0$ are imaginary of norm $-2n$ and have multiplicity $c(n)=\dim(V_n)$. As these multiplicities are exactly the coefficients of the j function, it is not surprising that j appears in the correction caused by the imaginary simple roots. This discussion is slightly misleading because we have implied that we obtain the product formula of the j function as the denominator formula of the monster Lie algebra by using our knowledge of the simple roots; in fact we really have to use this argument in reverse, using the product formula for the j function in order to work out what the simple roots of the monster Lie algebra are.

We will now extract information about the coefficients of the Thompson series $T_g(\tau)$ from a twisted denominator formula for the monster Lie algebra. For an arbitrary generalized Kac-Moody algebra there is a more high powered version of the Weyl denominator formula which states that

$$\Lambda(E) = H_*(E),$$

where E is the subalgebra corresponding to the positive roots. Here $\Lambda(E) = \Lambda^0(E)\ominus\Lambda^1(E)\oplus\Lambda^2(E)\ldots$ is the alternating sum of the exterior powers of E, and similarly $H_*(E)$ is the alternating sum of the homology groups $H_i(E)$ of the Lie algebra E (see [Car]). This identity is true for any Lie algebra because the H_i's are the homology groups of a complex whose terms are the Λ^i's. The left hand side corresponds to a product over the positive roots because $\Lambda(A\oplus B)=\Lambda(A)\otimes\Lambda(B)$, $\Lambda(A)=1-A$ if A is one dimensional, and E is the sum of $\mathrm{mult}(\alpha)$ one dimensional spaces for each positive root α. It is more difficult to identify H_* with a sum over the Weyl group, and we do this roughly as follows. For Kac-Moody algebras H_i turns out to have dimension equal to the number of elements in the Weyl group of length i; for finite dimensional Lie algebras this was first observed by Bott, and was used by Kostant to give a homological proof of the Weyl character formula. The sum over the homology groups can therefore be identified with a sum over the Weyl group. For generalized Kac-Moody algebras things are a bit more complicated. The sum over the homology groups becomes a sum over the Weyl group, which is generated by an involution for each simple root, and the things we sum contain terms corresponding to the imaginary simple roots.

Anyway, we can work out the homology groups of E explicitly provided we know the simple roots of our Lie algebra; for example, the first homology group H_1 is the sum of the simple root spaces. For the monster Lie algebra we have worked out the simple roots using its denominator formula, which is the product formula for the j function, and the homology groups of E turn out to be $H_0 = \mathbf{R}$, $H_1 = \sum_{n\in\mathbf{Z}} V_n p q^n$, $H_2 = \sum_{m>0} V_m p^{m+1}$, and all the higher homology groups are 0. Each homology group is a $\mathbf{Z}^2$-graded representation of the monster, and we use the p's and q's to keep track of the grading. If we substitute these values into the formula $\Lambda(E) = H_*$ we find that

$$\Lambda(\sum_{n\in\mathbf{Z},m>0} V_{mn} p^m q^n) = \sum_m V_m p^{m+1} - \sum_n V_n p q^n.$$

Both sides of this are virtual graded representations of the monster. If we replace everything by its dimension we recover the product formula for the j function. More generally, we can take the trace of some element of the monster on both sides, which after some calculation gives the identity

$$p^{-1}\exp\Big(-\sum_{i>0}\sum_{m>0,n\in\mathbf{Z}} \mathrm{Tr}(g^i|V_{mn}) p^{mi} q^{ni}/i\Big) = \sum_{m\in\mathbf{Z}} \mathrm{Tr}(g|V_m) p^m - \sum_{n\in\mathbf{Z}} \mathrm{Tr}(g|V_n) q^n$$

where $\mathrm{Tr}(g|V_n)$ is the trace of g on the vector space V_n.

These relations between the coefficients of the Thompson series turn out to be strong enough to characterize them and check that they are Hauptmoduls for genus 0 subgroups. Unfortunately this final step of the proof is rather messy. The relations above determine the Thompson series from their first few coefficients. Norton and Koike checked that certain modular functions of genus 0 also satisfy the same recursion relations. We can therefore prove that the Thompson series $T_g(q)$ are modular functions of genus 0 by checking that the first few coefficients of both functions are the same. Norton has conjectured that Hauptmoduls with integer coefficients are essentially the same as functions satisfying relations similar to the ones above, and a conceptual proof or explanation of this would be a big improvement to the final step of the proof. (It should be possible to prove this conjecture by a very long and tedious case by case check, because all functions which are either Hauptmoduls or which satisfy the relations above can be listed explicitly.)
